There were three stages in the development of detergents: first, their appearance on the market and the addition of builders to improve their action upon cotton; they were a boon, especially in hard water. The second step was that of adding a bleach, and the third was the addition of a white substance with blue fluorescence—the optical bleach to give the "whiter-than-white" look. This is a dye and a very bad one because it is not fast to detergents; it is now broadcast throughout the washtub. It might be possible for the dyestuff makers to produce an optical bleach that is fast. Alternatively, following Mr. Ward's suggestion of different products for different duties, Dr. Lawrence suggested three types of detergent; one, consisting of detergent and builder only for use in washing up, for paint, etc., and for all coloured and dark textiles; the second would contain also the bleach for occasional use on whites; and the third would have detergent, bleach and the fluorescent optical bleach for those who wanted it. The makers should sell each in a distinctively coloured package—say, red, blue or white—upon which their name and instructions should be printed. Members of the public have been so confused by advertisement campaigns that they either fail to read the maker's directions or mistakenly suppose that all brands are equally good.

Dr. Lawrence said that all the intelligent young women whom he had questioned said that they used only carboxylate soap for their clothes and synthetic detergents (often those containing the bleaches) only for domestic housework—a duty for which their formulation makes them unsuitable and uneconomical.

The basic reason for holding the meeting was the policy of marketing detergents which are compounded as Jacks-of-all-trades and masters of none. There seems to be a need for fundamental research into the nature of the soil responsible for the greying of whites and of the forces responsible for its persistent adhesion. The paradox which this material presents is that it is removed by the non-detergent components and not by the soap.

In the discussion, much evidence was given of complaints of faults arising during washing being reported to the manufacturer of the textile article. Patchy changes of shade due to the optical bleaches occur on twin-sets; rhodamine pink is not fast to detergents. The maximum degree of brightness from the optical bleach can be built up in an article free of it by washing in suds, containing none, from other articles which have been loaded. Faults due to the perborate chemical bleach include yellowing, said to be due to incomplete rinsing, and loss of colour, both generally and in spots. The latter were attributed to incomplete solution of the perborate in the hot water before the articles to be washed were put in. Two speakers said that they had seen advertisements for detergents on television in which this incorrect and dangerous procedure was shown. It was generally agreed that loss of strength is not a problem and that when it does occur, faulty rinsing is the cause. Bleaching on the line, especially during drying in sunlight, was also attributed to this cause. Serious disquiet was expressed at a report of the addition of bleaches containing chlorine to domestic detergents in the United States, and of their possible use in Britain.

A number of speakers made it clear that they considered that some detergent compositions, likely to cause damage to some textile goods of high quality, are being sold to housewives without adequate and sufficiently clear instructions. It is claimed by the manufacturers of these detergents that their inquiry and education services find none of the faults described. On the other hand, a manufacturer of baby clothes who guarantees to replace faulty goods has reported numerous complaints of change of colour, and said that a recommendation to use a selected detergent free from the objectionable additions has led to a large decrease in the number of complaints. He suggested clear classification of all detergents into two groups, one for whites and one for coloured goods. This and similar labelling proposals were received with applause by the meeting. It was stated that the dyestuff makers were unable to produce an optical bleach fast to detergents.

Dr. A. S. C. Lawrence, summing up, said that three main points had emerged from the meeting. First, that the light-fast dyes, which the dye maker can produce, require dyeing processes to make them fast to detergent compositions as now generally sold and this involves extra cost. Secondly, that the textile manufacturer receives the complaints, for the obvious reason that a woman who has purchased a relatively expensive article will complain to the shop where she bought it rather than write to the manufacturer from whom she has obtained a few pennyworth of detergent. Thirdly, that communication of highly technical matters to and from a technologically ignorant public is impossible, and the claims of success of inquiry and education services of the detergent manufacturers must be regarded with suspicion. New textile goods heavily loaded with optical bleach are already being sold, so that a ban on fluorescent brighteners in detergents would not be enough. It seems that some co-operative standard of labelling by makers of detergents, to distinguish in a simple and unequivocal manner for the ordinary housewife the basic types of composition, is the only satisfactory solution and one much overdue. Alternatively, makers of textiles will have to label their goods, specifying a safe detergent, until the makers of the present potentially harmful compositions, so widely sold, are driven to a more critical consideration of their duty to the public. A. S. C. LAWRENCE

FORESTRY IN THE UNITED KINGDOM

WHILE the Society of Foresters of Great Britain, having been formed in 1925, is the youngest of the British societies concerned with forestry, its membership is the most representative of the profession as, although it has an ordinary membership open to all who are interested, it caters primarily for the university graduate and others with equivalent qualifications. Its journal, *Forestry*, is published twice yearly. During the past year, it has published about a dozen original articles ranging over a very wide field, tending to be ecological rather than technical, though some of them link the two aspects; for example, a study of the effect of rate of growth on the density of timber.

The opening article in the 1958 volume is a thoughtful study by G. B. Ryle (at the time, the Forestry Commission director for Wales) on the social problems and possible developments in upland grazing areas where forestry is the obvious alternative use to sheep farming. A strong case is made for integration of farming and forestry, both uses being taken equally into account; action should be co-ordinated by combined councils and the mistakes of the past should be avoided. There have been faults on both sides, the agriculturist seeing the problem as one of maintaining the farm with the help of subsidies, etc., even when it is uneconomical, or less economical than alternative uses, while the forester has tended to overlook the fact that both winter and summer feed must be available to a sheep farm. Ryle also adduces fairly conclusive evidence that forestry gives more on-the-spot employment than sheep farming—probably twice as much—and stresses the need for improved housing as extensions of existing communities rather than new isolated centres.

A study of the mineral content of standing pine crops on the Culbin Sands by T. W. Wright and G. M. Will shows that a maturing crop with about 50 tons of dry organic substance contains about 170 lb. nitrate, 20 lb. phosphate, 100 lb. potassium, 160 lb. calcium and 32 lb. magnesium, of which about one-third to one-quarter is in the leaves and so returned to the ground annually; the wood, which alone is ultimately removed (provided the bark is peeled on the spot), contains less than one-fifth of the total. These figures, despite their smallness, are of considerable significance in relation to the very low mineral content of the blown sand.

Two papers deal with different aspects of a field that is attracting increasing attention, namely, the relation between the physical conditions, both natural and due to manipulation, under which trees are grown, and the properties of the timber they produce. Studies of site factors influencing growth are discussed in another two papers dealing, respectively, with wind effects and the measurement of light intensity. Taxonomic studies are represented by a paper on the elms of south Cambridgeshire and one on the named variants of the Scots pine. In view of the importance of the latter tree in afforestation and its wide distribution and range of forms, this analysis of 144 terms already published is a most useful contribution: it describes no less than twenty-six geographical varieties and twenty-five habit forms, together with many named variations in bark, foliage, cones, timber and seed.

The Royal Scottish Forestry Society was founded as the Royal Scottish Arboricultural Society in 1855 and its published transactions have developed into the current quarterly *Scottish Forestry*. While this Society draws its membership from a wider field than the Society of Foresters of Great Britain, and has a much bigger proportion of the non-professional element, its journal regularly includes original articles of considerable interest and value. Among those appearing during the year, mention may be made of a paper on the practical issue of using a knowledge of the life-history of the fungus (*Keithia*) which is liable to affect seriously the growth of *Thuja* seedlings, to raise healthy nursery stock of this tree; isolated nurseries used once only or in rotation, with due precautions to avoid sources of infection, are the solution. There is an interesting paper on the variation of susceptibility of European larch of different seed origins to frost, and another on 'group strike' by lightning, a case being reported of one hundred trees dying with only two showing actual scars, and a comparable case in a nursery. The morphological field is represented by a paper on bark variation in birch and its relation to figured wood.

The present Royal Forestry Society of England and Wales was founded in 1882 as the English Arboricultural Society, on similar lines to its Scottish counterpart. Its transactions appeared from 1884, becoming the *Quarterly Journal of Forestry* in 1907. As might be expected, a very similar range of original papers is being published, including in 1958 three on the properties of coniferous timbers as affected by treatment during growth, one on the effect of liming ploughed or unploughed upland moors, and one on the 'mechanized forest'.

Mention should not be omitted of the *Empire Forestry Review*, published quarterly by the Empire Forestry Association, which includes a proportion of original articles on British forestry among its much wider coverage; these are chosen primarily for their general interest though, of course, forestry issues are very similar all over the world. The chief items of this type in 1958 are on desirable road density in plantations and intensive methods of raising coniferous seedlings. In addition, there are the 'Men of the Trees' publishing *Trees* two or three times a year.

FOOD INVESTIGATIONS

THE recently published report of the Food Investigation Board* for 1957 also covers the work of the Torry Research Station and the Humber Laboratory concerning the improved handling and processing of fish; the Low Temperature Research Station on meat, eggs and various plant foods; and the Ditton Laboratory and the Covent Garden laboratory concerned mainly with conditions of storage for fruit and vegetables.

A report of this nature provides an excellent illustration of the complexity of the problems associated with the maintenance of an all-the-year-round supply of food in an industrialized, urbanized community. In the main, the work is concerned with preserving food and this requires a study of differences in the initial state of the food, of the conditions of handling to which it may be subjected, and of methods of detecting early stages of deterioration, quite as much as a study of all aspects of the different methods of preservation, which include such varied means as the use of antibiotic ice, electronic radiation, electrostatic smoking, vacuum freeze-drying, gas storage, etc.

The Board stresses "the vital importance of the closest possible co-operation with the appropriate user industry from the outset of a research through all its stages to its final implementation". Several of the investigations concerning fish were made at the request of the White Fish Authority, the Herring Industry Board, and the National Federation of Fishmongers, and a committee of the National Farmers' Union was consulted when the research programme of the Ditton Laboratory was being planned. This is welcome collaboration and should not only ensure direction of effort towards the problems most urgently in need of solution but also speedy application of any solutions which might be found.

REMANENT MAGNETISM OF THE ALLARD LAKE ILMENITES

By CHARLES M. CARMICHAEL

Department of Geophysics, University College, University of Western Ontario

THE Allard Lake region of Quebec contains numerous outcrops of massive ilmenite enclosed in Grenville-type anorthosite of pre-Cambrian age. Hammond[1] has described the region, particularly the Lac Tio deposit, which is the largest of its type in the world.

Although the ore is usually referred to as ilmenite, it should be called hemoilmenite, since it consists of about 70 per cent ilmenite ($FeTiO_3$) and 25 per cent hematite (Fe_2O_3), with the remainder being largely composed of feldspar, pyroxene and pyrite. The massive ore consists of relatively large crystals averaging about 3–5 mm. in diameter. The hemoilmenite solidified originally in homogeneous crystals, and then upon cooling separated by exsolution into an ilmenite-rich phase and a hematite-rich phase. The hematite-rich phase has exsolved in the form of thin discontinuous lamellæ with their long and intermediate axes in the basal plane of the rhombohedral host-crystal. Thus the lamellæ have the general

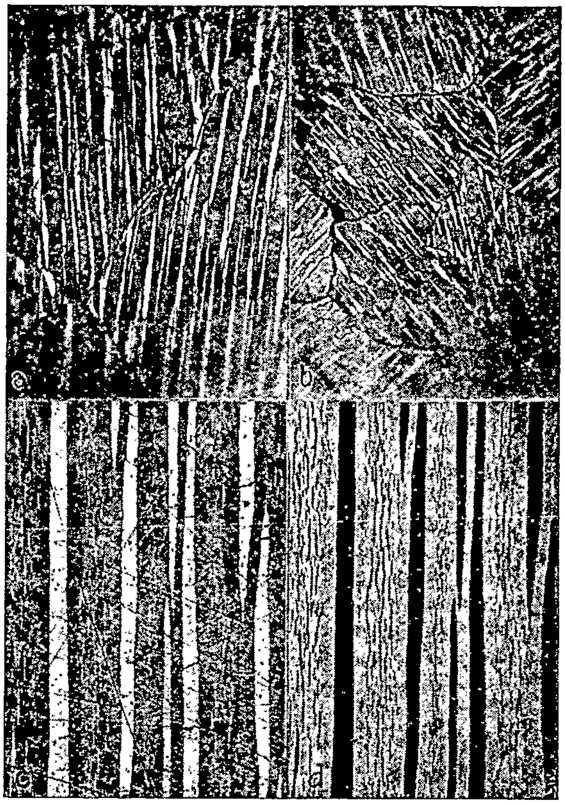

Fig. 1. Polished surfaces of hemoilmenite showing exsolved hematite lamellæ. The direction of the remanent magnetization is from top to bottom in each photograph

shape of thin elliptical disks with one long, one intermediate and one short axis (see Fig. 1).

The hematite lamellæ have exsolved in two distinct size-ranges (see Fig. 1*c*). The simplest explanation for this is that there are two plateaux in the cooling curve of the deposits : a long period of fairly constant temperature during which the large lamellæ exsolved, followed by a relatively rapid drop in temperature, and then a second constant-temperature period during which the small lamellæ were formed. The absence of small lamellæ in the ilmenite adjacent to the large lamellæ indicates a low hematite content, probably due to diffusion of ferric ions from the host into the large lamellæ. There are also small lamellæ of ilmenite in the central part of the large hematite lamellæ. Unfortunately, the steep sides of the hematite–ilmenite solvus curve as given by Nicholls[2] and modified by Uyeda (private communication in 1957 and ref. 3) make it difficult to fix the temperature plateaux accurately. However, the composition of the hematite-rich phase of 0·86 Fe_2O_3, 0·14 $FeTiO_3$ and of the ilmenite-rich phase of 0·87 $FeTiO_3$, 0·13 Fe_2O_3, as given by Uyeda (private communication, 1957) for one sample of Allard Lake ore, indicates a temperature during exsolution of about 700° C. or less. Thus it is not known whether the lamellæ were exsolved before or after they passed through their Curie point, which is about 580° C.

The directions of the remanent magnetization of samples taken from the deposits show a wide scatter, both in the angle of declination and in the magnitude of the angle of inclination, but the signs of the angles of inclination are all negative, that is, the north end of the magnetic vector is inclined above the horizontal. This accounts for the pronounced negative anomalies, in the aeromagnetic survey of the region, over the ilmenite deposits, as reported by Hammond[1] and Bourret[4]. Balsley and Buddington[5] have also reported negative aeromagnetic anomalies over hemoilmenite-bearing rocks in the Adirondacks.

There is a high correlation between the direction of the remanent magnetization of a specimen of the ore and the average direction of the long axes of the hematite lamellæ in the crystals which make up the specimen. In Fig. 1 the remanent vector lies in the polished surface and is directed from top to bottom in each photograph. This correlation between the direction of the remanent magnetization and that of the lamellæ has also been confirmed in single crystals large enough to be measured separately. This suggests that the present remanent magnetization of the ore is due mainly to the hematite lamellæ. Because of the shape effect, the lamellæ should retain only the component of their magnetization parallel to the long axis of each lamella, regardless of the direction of the magnetizing field. This is supported by the difference in intensity of the remanent magnetization of specimens similar in all respects except in the degree of alignment of the directions of the lamellæ from crystal to crystal throughout the specimen. The intensities of the remanent magnetization of the specimens photographed in Fig. 1*a* and 1*b* are, respectively, 0·028 E.M.U./gm. and 0·011 E.M.U./gm. Single crystals have been measured with intensities of more than 0·03 E.M.U./gm. and some massive samples have intensities of less than 0·005 E.M.U./gm.

A further test of the hypothesis that the remanent magnetic field is due to the hematite lamellæ was conducted by dissolving the hematite lamellæ out of the host ilmenite and comparing the intensity of the remanent magnetization before and after solution. Fig. 1*c* shows a typical polished surface and Fig. 1*d* the same surface after the exposed lamellæ of hematite had been dissolved out. Because the lamellæ are discontinuous and completely enclosed in the ilmenite phase, only those exposed on the surface can be dissolved. Thus thin sections of ore were used, ranging in thickness from about 2 mm. to 0·2 mm. Some typical results are shown in Table 1. There was no change in the direction of the remanent magnetization during the solution process. The sections used were cut so that the remanent vector lay in the plane of the section and so that the intermediate axes of the lamellæ were perpendicular to this plane in order to expose a maximum number of lamellæ at the surfaces. The sections with thicknesses of 2 mm. and 0·4 mm. were cut from specimens of typically massive ore of relatively high intensity, whereas the section 0·2 mm. thick was cut from a large single crystal about 12 mm. in diameter.

Since the present remanent magnetization of the ilmenite deposits is due to the exsolved hematite lamellæ and is directed in the average direction of the long axes of these lamellæ, the direction of the remanent magnetization is not necessarily the same

Table 1

Thickness of section (mm.)	Original intensity of magnetization (E.M.U./gm.)	Intensity of magnetization after surface lamellæ dissolved (E.M.U./gm.)	Decrease in intensity of remanent magnetization (per cent)
2·0	0·0264	0·0254	4
0·4	0·0281	0·0033	88
0·2	0·0322	< 0·0002	> 99·6

as that of the Earth's magnetic field which existed while the deposits were being magnetized. If the directions of the crystal axes throughout the deposits were completely random, it should be possible to determine the direction of the Earth's field at the time of cooling of the deposits by averaging the directions of the remanent magnetizations of a large number of samples. Unfortunately, the specimens from the Allard Lake deposits show marked alignment of the c, or principal, crystallographic axes of the grains, perhaps due to stress or other geological factors, so that little information about the Earth's field in the past can be obtained by measuring the direction of the present remanent magnetization.

Whereas only the Allard Lake ilmenites have been used in this investigation, it is probable that these results are applicable to other ilmenite deposits or rocks containing ilmenite of similar compositions, perhaps indicating that these rocks should not be used for palæomagnetic work. Investigations are continuing on other aspects of the magnetic properties of the Allard Lake deposits, including the reversed orientation.

ABSORPTION SPECTRA AND ASSOCIATED PHOTOCONDUCTIVITY OF PURE AND DECOMPOSED CRYSTALS OF THALLOUS AZIDE

By B. L. EVANS and A. D. YOFFE

Research Laboratory for the Physics and Chemistry of Solids, Department of Physics, Cambridge

THE physical and optical properties of thallous azide (TlN_3) suggest that the lattice is predominantly ionic but some sharing of valence electrons occurs. This may be attributed[1] to the large difference in energy between the ionization potential of the thallium atom and the electron affinity of the azide radical. It has been found that thallous azide is a photoconductor when irradiated with light of wave-length corresponding to the fundamental absorption edge.

In the experiments to be described, the crystal of thallous azide was held against two platinum or silver electrodes in such a manner that the incident beam of light irradiated the major morphological face. Measurements were made with the crystal under vacuum and the photocurrent measured as a function of the wave-length of incident light. In addition, measurements have been made to determine the variation of photocurrent with intensity of the light.

The optical absorption spectrum of a single crystal of thallous azide is shown in Fig. 1. In addition to the long-wave-length tail, the absorption spectrum possesses a 'shoulder' in the vicinity of 3000 A. At shorter wave-lengths the absorption rises rapidly to the limit of measurement at 2000 A.

The spectral distribution of photocurrent in a pure crystal of thallous azide is shown in Fig. 2, curve *A*, where the applied voltage gradient was 60 V./cm. There is a subsidiary maximum in the photocurrent at 4300–4350 A. At wave-lengths less than 4000 A. the photocurrent increases rapidly. Measurements could not be made at wave-lengths less than 2600 A. as the output of light from the source used (xenon lamp) is very small at these wave-lengths. If silver electrodes are used instead of platinum electrodes, then the spectral distribution of photocurrent is similar to that of curve *A*, except that the rise in photocurrent at short wave-lengths does not occur until 3600 A.

The crystal used to obtain curve *A*, Fig. 2, was then irradiated, while still under vacuum, through a glass filter, by the output of light from a 100-W. mercury-vapour lamp. The spectral distribution of photocurrent was then measured and is given by curve *B*, Fig. 2. The applied voltage gradient was 160 V./cm. It will be seen that the photocurrent has been reduced to one-tenth of its original value and the rise in photocurrent at short wave-lengths has been eliminated. The maximum photocurrent occurs at 4250 A. The photochemical decomposition resulting from irradiation by the mercury-vapour lamp results in the formation of a thin film of thallium on the surface of the crystal. This metallic film gives rise to a new absorption band. In Fig. 3 the difference in absorption coefficients between an irradiated and pure crystal of thallous azide are plotted. Curves *A*, *B* and *C* of Fig. 3 show how this band develops with increasing time of irradiation.

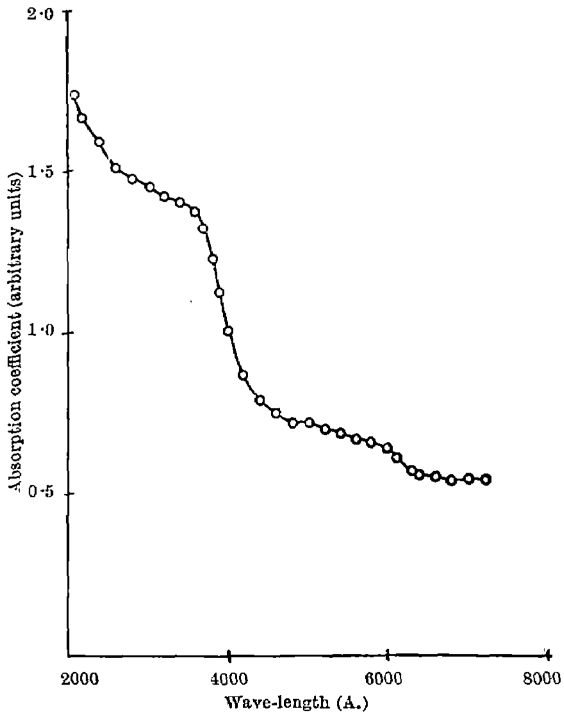

Fig. 1. The absorption spectrum of an undecomposed single crystal of thallous azide

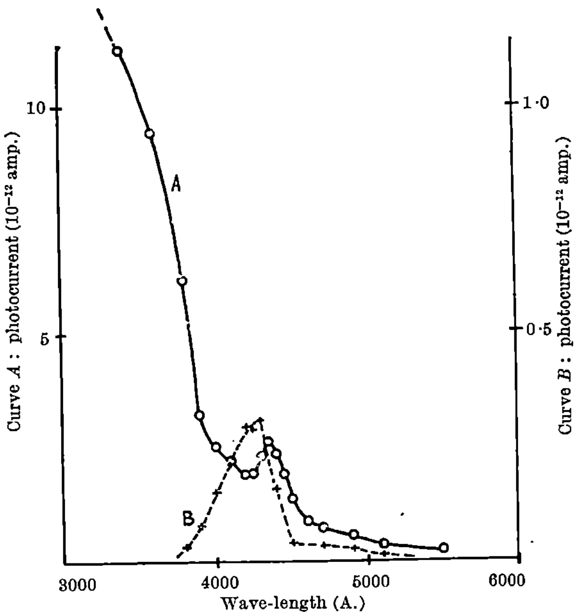

Fig. 2. Spectral distribution of the photocurrent in thallous azide at room temperature calculated for an equal intensity at each wave-length. Curve A undecomposed crystal; curve B photochemically decomposed crystal

The efficiency of photochemical decomposition increases with decreasing wave-length.

When a crystal of thallous azide (melting point 334° C.) is heated for 10 hr. at 230° C. metal specks are formed at the surface of the crystal. In this experiment, however, the metal is formed as relatively large discrete particles which can be up to 10^{-2} mm. in diameter. These particles appear in a matrix of apparently undecomposed thallous azide and do not give rise to a new absorption band as in the case of thallium produced photochemically. The spectral distribution of photocurrent of thallous azide decomposed thermally is shown in Fig. 4 (voltage gradient 80 V./cm.). There is a 'shoulder' at 4250 A., but the photocurrent rises sharply at shorter wave-lengths, as observed with pure thallous azide.

In order to obtain a uniform distribution of metallic thallium throughout a crystal of thallous azide, radioactive thallium-204 was used in the preparation of the thallous azide. These crystals were made by S. K. Deb. One year after preparation the crystals appeared black in reflected light and red in transmitted light. Metallic thallium is formed in the crystal by a mechanism similar to that described for silver azide[2] and also by irradiation damage due to the fast β-particles that are emitted during decay of the radioactive isotope. The intensity of the light source used in the previous experiments was not sufficient to give rise to a detectable photocurrent in these 'black' crystals. However, by using a 100-W. mercury-vapour lamp in conjunction with filters of narrow wave-band it was possible to show that the general features of the photocurrent – wave-length response resembled that shown in Fig. 4, although on a much reduced scale.

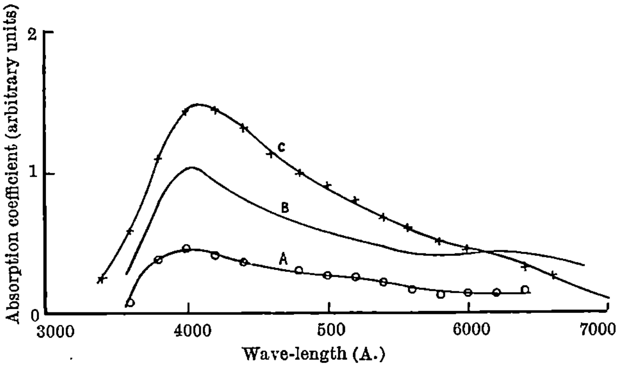

Fig. 3. Absorption spectra of thallium film formed during photochemical decomposition of thallous azide. Curve A, crystal irradiated for 1½ hr.; B, 4 hr.; C, 9 hr.

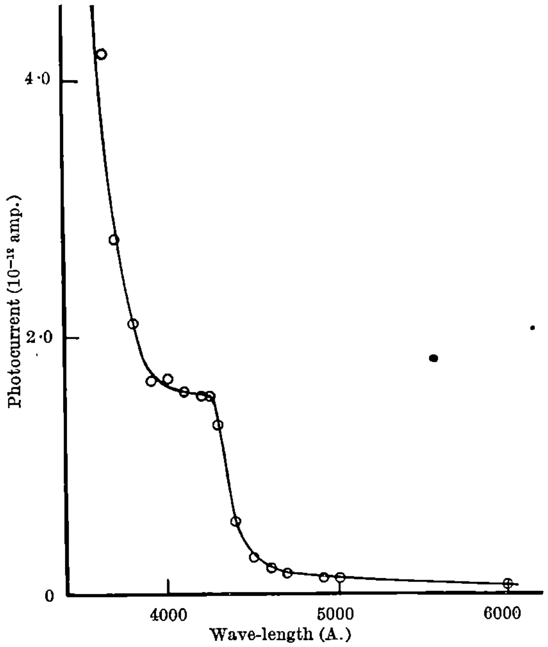

Fig. 4. Spectral distribution of the photocurrent in thermally decomposed thallous azide calculated for an equal intensity at each wave-length

In order to interpret these experimental results we first consider the photoconductivity of pure thallous azide given by curve A, Fig. 2. The subsidiary maximum at 4300–4350 A. may be identified with the thermal dissociation of optically formed excitons. The optical transition of electrons from the full band to the exciton band of the crystal gives rise to the 'shoulder' at about 3000 A. shown by the absorption spectrum of Fig. 1. The subsidiary photoconduction maxima are dependent on temperature and it was possible to determine an activation energy for the thermal dissociation of excitons in the thallous azide. The steep rise in photocurrent for wave-lengths less than 4000 A. arises from direct optical transitions from the full band to the conduction band of thallous azide. The corresponding optical absorption for this process is given in Fig. 1 by the steep rise in absorption coefficient at wave-lengths less than 3000 A. Hence over nearly the whole range of wave-length of curve A, Fig. 2, the observed photocurrent is the sum of two components. The first component, C_x, having a maximum at 4350 A., is the spectral distribution of photocurrent due to the dissociation of optically formed excitons by the thermal energy of the thallous azide lattice. The second component C_S is the spectral distribution of photocurrent due to direct optical transitions between the full band and conduction band of the crystal. Component C_S may be represented by an equation of the form[3]:

$$\frac{x}{\alpha} = \frac{1}{1 + \exp\{c(\varepsilon_0 - \varepsilon)\}} \qquad (1)$$

where c is a constant, ε is the energy of the incident light, ε_0 is the energy at the 'threshold' wave-length and x is the observed photocurrent which increases to a maximum value α (not measured). For $x \ll \alpha$ this equation may be written in the form:

$$\ln_e x = c\varepsilon + \ln_e \alpha - c\varepsilon_0 \qquad (2)$$

Curve A, Fig. 2, was plotted as $\ln_e x$ against ε and in this form (Fig. 5) yielded several points of additional information. It will be seen from Fig. 5 that for an incident light energy greater than 3·1 eV. the points of $\ln x$ lie on a straight line which changes to a line having a different slope for energies greater than 3·44 eV. This change in slope at $\varepsilon = 3\cdot 44$ eV. may be completely accounted for in terms of recombination, of conduction electrons and positive holes. When recombination occurs the electron – positive hole density is high (due to the increasing absorption coefficient) and the equilibrium photocurrent x^1, as measured, is given by $x^1 = x^{1/2}$, where x is the photocurrent that would be measured in the absence of recombination. Hence $\ln x = 2 \ln x^1$, and if this modification is applied it is found that the points of $\ln x$ for $\varepsilon > 3\cdot 44$ lie on a straight line having the same slope as that of $\ln x$ against ε for $3\cdot 1 < \varepsilon < 3\cdot 44$. This leads to the conclusion that $C_x = 0$ for $\varepsilon > 3\cdot 1$ and the spectral distribution of C_s can thus be determined for all ε. Knowing the contribution to the observed photocurrent of C_s it is thus possible to plot the spectral distribution of photocurrent due to C_x.

A similar analysis may be made for the photocurrent observed in thermally decomposed thallous azide. It is again found that recombination of electrons and positive holes occurs for C_s when $\varepsilon > 3\cdot 44$ eV. The spectral distribution of C_x so obtained is found to be identical in form (but reduced in amplitude) when compared with the spectral distribution of C_x for pure thallous azide, except that the maximum, as in Fig. 4, occurs at 4250 A., whereas for undecomposed thallous azide the maximum occurs at 4300–4350 A.

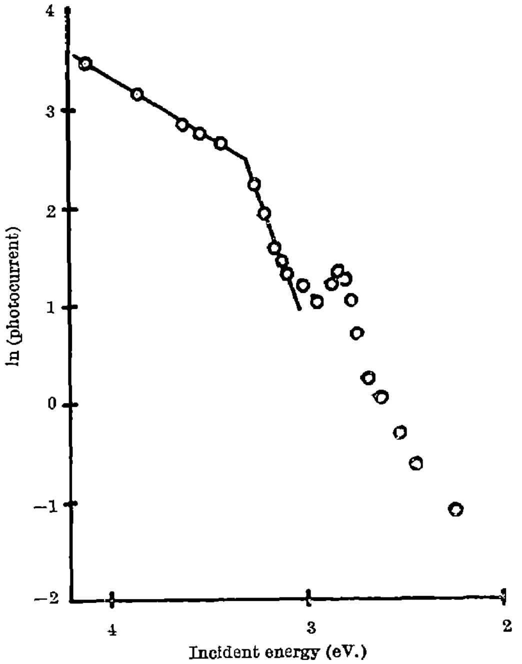

Fig. 5. Plot of ln (photocurrent) against energy of incident light, for curve A, Fig. 2

The spectral distribution of photocurrent obtained with photochemically decomposed thallous azide as given by curve B, Fig. 2, is identical to that calculated for C_x of thermally decomposed thallous azide with the important exception that curve B, Fig. 2, exhibits a long-wave-length tail between 4600 A. and 5200 A.

It has been found, as expected, that the long-wave-length side of C_x for pure and thermally decomposed thallous azide is of the form given by equation 2 and also that electron – positive hole recombination occurs in the vicinity of the maximum. It is therefore likely that the short wave-length decrease in photocurrent of C_x and shown, for example, by curve B, Fig. 2, is due to electron – positive hole recombination. The results so far described may be summarized, for example, with reference to the spectral distribution of photocurrent for undecomposed thallous azide given by curve A, Fig. 2. At long wave-lengths, namely, about 5000 A., the photocurrent due to $C_x + C_s$ is not inhibited by recombination. The absorption steadily increases with decreasing wave-length and the subsidiary maximum at 4300–4350 A. is achieved when recombination limits the rapidly increasing value of C_x. C_x then decreases to zero at 3980 A. (3·1 eV.). For wave-lengths less than 3980 A. the photocurrent is entirely due to C_s and this component is then unaffected by recombination until 3600 A. (3·44 eV.). In the absence of recombination, the photocurrent x will be proportional to I, the intensity of incident light. Where recombination limits the observed value of the photocurrent, then $x \propto I^{1/2}$. In order to verify these predictions involving recombination, the photocurrent of undecomposed thallous azide was measured as a function of the intensity of light at various wave-lengths. Table 1 gives the predicted and observed intensity – photocurrent relations

Table 1

Wave-length (A.)	Predicted	Observed
4650	I	I
4350	$I^{1/2}$	$I^{1/2}$
3800	I	c. I*
3350	$I^{1/2}$	c. $I^{1/2}$*

* Large error of measurement due to small intensity of light source.

The proposed mechanism of photoconduction in pure thallous azide is able to account quite well for the observed spectral distribution, but it still remains to explain the different photoconductive behaviour exhibited by pure and decomposed thallous azide.

In thallous azide decomposed thermally the metallic nuclei are present as discrete specks, the photocurrent has been reduced in magnitude and the minimum, which occurs at 4250 A. for pure thallous azide, has been lost because the maximum of C_x has moved to shorter wave-lengths and now occurs at 4250 A. If we assume that the metal specks, by attracting Tl^+ ions, act as electron traps, then if the number of such traps, N, is smaller than x^1, the number of conduction electrons, then $x^1 = x - N/2$, where x is the number of conduction electrons in the absence of such traps. The consequent reduction in density of conduction electrons will (a) reduce the observed photocurrent, and (b) move the maximum of C_x to shorter wave-lengths as the reduced electron density will delay the onset of recombination.

In the case of radioactive thallous azide the very large number of submicroscopic metal specks will lead to an overall reduction in photocurrent due to the increased absorption and the large number of traps. The spectral distribution of photocurrent should be as in Fig. 4, and this is what is observed.

Photochemically decomposed thallous azide, however, possesses a large number of metal traps in the form of a metal film on the surface of the crystal. This metal film also reduces the amount of light absorbed by the crystal in the region of C_x. The rise in photocurrent for short wave-lengths has been completely eliminated due to the metal electron traps. Similarly, as in the case of thermally decomposed thallous azide, the maximum of C_x has moved to shorter wave-lengths. However, the photocurrent has a long-wave-length tail and this arises from C_s. The metal film is not effective as an electron trap at these longer wave-lengths about 5000 A. because of the small absorption of the thallous azide. This means that the photoelectrons are produced some distance below the crystal surface.

In conclusion, it must be noted that if an 'undecomposed' crystal of thallous azide is irradiated on one of the minor morphological faces, then the spectral distribution of photocurrent is the same as that shown in curve *B*, Fig. 2. It has been found, however, that such crystal faces are far more sensitive to photochemical decomposition than the major faces, presumably due to their higher surface energy. Crystals examined in this manner have undoubtedly undergone some photochemical decomposition.

GENETIC CONTROL OF CHROMOSOME PAIRING IN INTERGENERIC HYBRIDS WITH WHEAT

By DR. RALPH RILEY, VICTOR CHAPMAN and GORDON KIMBER
Plant Breeding Institute, Cambridge

It has been shown that in hexaploid common wheat, *Triticum vulgare* ($6x = 42$), control of the purely bivalent-forming, diploid-like, meiotic behaviour is exercised by a gene, or genes, on one particular chromosome[1]. In the absence of this chromosome, pairing can take place between equivalent, homœologous, chromosomes in each of the three genomes, so that wheat ceases to behave as a classical autosyndetic allopolyploid. The diploidizing mechanism was exposed by Riley and Chapman in studies of 20-chromosome nullihaploids and 40-chromosome nullisomics in the variety Holdfast[1,2], and was indicated in the simultaneous work of Sears and Okamoto[3] on crosses of monosomics of the variety Chinese Spring with diploid wheat.

Chromosome V of Chinese Spring carries the gene responsible for the restriction of homœologous pairing but it has not yet been possible to confirm, by crossing, that the Holdfast chromosome, designated *HH*, with the equivalent effect is homologous with V of Chinese Spring. This is very likely, however, since both nullisomics have similar deviations from the euploid phenotypes, and it is known that the phenotype of nullisomic V is very different from those of all the other nullisomics of Chinese Spring[4]. Moreover, both chromosomes are similar in morphology, being heterobrachial with one arm about twice the length of the other.

The utilization of the variation of many diploid species in the genus *Aegilops*, and of *Secale* species, in the improvement of wheat is limited because there is little or no pairing between the chromosomes of wheat and those of the diploids with which wheat is combined in intergeneric hybrids, so that foreign genes cannot be introduced into wheat chromosomes by recombination. Riley and Chapman suggested that the genetic mechanism which restricts pairing between homœologous chromosomes of wheat might also be responsible for the failure of wheat chromosomes to pair with those of some species in related genera. If this were so, intergeneric hybrids deficient for the chromosome carrying the diploidizing control would have some chromosomes of wheat paired with some of those of the diploid parent. To test this hypothesis the crosses *T. vulgare* Chinese Spring monosomic V ($6x - 1 = 41$) × *Aegilops longissima* ($2x = 14$) and *T. vulgare* Chinese Spring monosomic V ($6x - 1 = 41$) × *Secale cereale* King II ($2x = 14$) were made. The monosomic parents in these crosses produced gametes with 20 or 21 chromosomes depending on whether or not the monosomic chromosome was included. Consequently, from the same female parent, hybrids with 27 or 28 chromosomes resulted from the combination of the seven chromosomes of the male gamete with the alternative female gametes. Hybrids with 28 chromosomes possessed, and those with 27 chromosomes did not possess, chromosome V of Chinese Spring which carries the pairing control gene.

Chromosome pairing at first metaphase of meiosis has been compared in 27- and 28-chromosome hybrids and data from a few of the plants examined are presented with those for euhaploid and *HH* nullihaploid plants (Table 1). The haploid data are those previously collected in the variety Holdfast since no comparable material was available in Chinese Spring. However, the meiotic behaviour of euhaploids in Chinese Spring is similar to that in Holdfast[3], and it is likely that nullihaploid V in Chinese Spring would have a meiosis similar to that of nullihaploid *HH* in Holdfast.

There was a mean of only 1·96 bivalents per cell in the 28-chromosome hybrid with *A. longissima* and there were never more than six bivalents per cell (Fig. 1). This is slightly higher pairing than in euhaploids, and since there is little homology within

Table 1. MEIOTIC CHROMOSOME PAIRING IN HAPLOIDS AND HYBRIDS OF *T. vulgare* WITH AND WITHOUT THE CHROMOSOME CONDITIONING DIPLOID MEIOTIC BEHAVIOUR

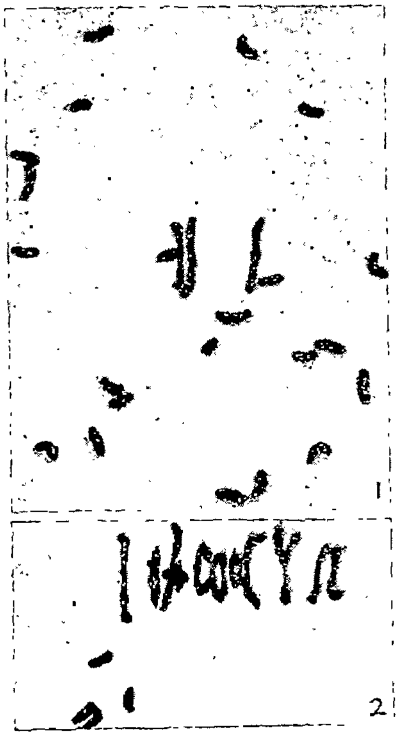
* Plus 2 associations of five.
† Plus 1 association of seven, 1 of eight and 1 of eleven.

the haploid complement of *A. longissima*[5] a small amount of pairing between wheat and *Aegilops* chromosomes must be indicated.

By contrast, chromosome pairing in the 27-chromosome hybrids with *A. longissima* was very high (Fig. 2). There were never fewer than 10 chromosomes paired and in some cells no chromosomes were left unpaired. The mean univalent frequency was almost the same as that of the 20-chromosome *HH* nullihaploid, so that the seven extra chromosomes were evidently often involved in pairing. Compared with the nullihaploid the mean bivalent frequency increased by more than half and the mean quadrivalent frequency increased 20 times, while there was about the same amount of trivalent formation. The frequent quadrivalents must have arisen from the conjugation of three homœologous chromosomes of some wheat groups with the equivalent *A. longissima* chromosomes. Apparently, therefore, the chromosomes of *A. longissima* will pair with those of wheat to a greatly increased extent when chromosome V is absent. For although quadrivalents are the only certain indication, presumably wheat and *Aegilops* chromosomes were also associated in bivalents and trivalents.



First metaphase of meiosis in Feulgen and orcein stained squashes of pollen mother cells of hybrids from the cross *T. vulgare* Chinese Spring monosomic V × *A. longissima*. (× 780)

Fig. 1. 28-chromosome hybrid with 3 bivalents and 22 univalents

Fig. 2. 27-chromosome hybrid with 1 quadrivalent, 1 trivalent, 8 bivalents and 4 univalents

The close relationship between *A. longissima* and *Aegilops speltoides*, the contributor of the *B* genome of *T. vulgare*, has been indicated by Riley, Unrau and Chapman[6]. Furthermore, the cytological affinity of all the genomes of wheat is shown by the intergenome pairing in *HH* nullihaploids, and from the pairing in hybrids between the putative diploid parents[1]. It is not surprising, therefore, that there is a close relationship between the chromosomes of *A. longissima* and those of each of the genomes of wheat. It is, however, remarkable that this affinity could normally be obscured by the diploidizing mechanism on chromosome V.

The amount of chromosome pairing in 28-chromosome hybrids between monosomic V and rye was not higher than that in euhaploid *T. vulgare* (Table 1). There is thus probably no pairing between wheat and rye chromosomes in normal hybrids. However, while there was much more pairing in the 27-chromosome hybrids from the same parents, and as many as 21 chromosomes could be involved in associations in one cell, there were on average fewer chromosomes paired than in *HH* nullihaploids of Holdfast. The 27-chromosome plants showed means of about one fewer bivalents per cell and this may reflect some interference, by rye, with pairing which occurs in nullihaploids. It is also possible, however, that the apparent differences may have resulted from the selection of cells scored, which was often compelled by the difficulty of interpreting cells with much pairing due to the attenuated and clumped nature of the chromosomes in rye hybrids deficient for chromosome V. The appearance of the chromosomes was normal in 28-chromosome hybrids with rye and in both types of *A. longissima* hybrid.

However, in the 27-chromosome hybrids there was about the same number of trivalents as in nullihaploids, but more than four times as many quadrivalents. The quadrivalents must have resulted from associations of homœologous chromosomes from each of the three genomes of wheat with a rye chromosome. Since rye chromosomes could pair with wheat chromosomes in quadrivalents it may be that they were also conjugated with wheat chromosomes in bivalents and trivalents. However, the frequency of rye–wheat pairing must have been low compared, for example, with the amount of *A. longissima*–wheat pairing. Nevertheless the evidence of quadrivalents alone is sufficient to show that, in the absence of V, rye and wheat chromosomes can pair, even though this rarely, if ever, happens in euploid hybrids.

Furthermore, in the 27-chromosome hybrids with rye, there were some large complexes, associated by chiasmata, and involving up to eleven chromosomes. These occurred in about five per cent of first metaphase cells but were often so complex that they defied interpretation and so such cells are under-represented in the analyses recorded. The large complexes probably arose because there is not a strict one-to-one relationship between rye chromosomes and wheat homœologous groups; rather, certain rye chromosomes must have affinities with the chromosomes of two wheat groups. That is, the rye chromosomes differ from chromosomes of the wheat groups by translocations, and for associations of more than eight to occur the rye complement must differ from the wheat genomes by at least two translocations involving three pairs. Annual rye differs from perennial rye by two translocations involving three chromosome pairs[7]. If the translocations which differentiate the rye species are the same as those which differentiate annual rye from the wheat genomes, then there would be no associations larger than quadrivalents in 27-chromosome hybrids involving perennial rye. If this could be shown it would indicate the primitive structure of the perennial rye genome and the derived nature of the annual rye genome, and so would clarify the general understanding of the origins and phylogeny of cultivated rye.

The chromosomes of rye and *A. longissima* show marked differences in their capacity to pair with wheat chromosomes in the absence of chromosome V. In view of the present evidence on the genetic control of pairing, the dangers of drawing phylogenetic conclusions from pairing in hybrids are apparent. Nevertheless, the differences between the rye and *Aegilops* derivatives may, with caution, be taken to indicate the greater evolutionary divergence of rye and wheat, compared with *Aegilops* and wheat, further evidence of which is the failure of rye chromosomes fully to match the wheat groups.

The present evidence on the powerful influence of the diploidizing control of hexaploid wheat on chromosome pairing in hybrids leads to two main conclusions. First, it is apparent that the possible influence of genetic situations such as that in wheat must be taken into consideration whenever chromosome pairing in hybrids involving polyploids is used in the interpretation of phylogenetic relationships. The chromosome pairing in crosses with polyploids should be compared with that in hybrids with the diploids from which the polyploids were derived. The effect of genes isolating the genomes of the polyploids and interfering with the expression of pairing affinities at meiosis might then be detected.

Secondly, since it is apparent that the barrier to the pairing and recombination of wheat chromosomes and those of some related species in other genera can be removed by the exclusion of chromosome V, the reservoirs of genetic variation upon which the wheat breeder can now draw are greatly increased. All the diploid species of wheat and *Aegilops* are comparatively closely related and have chromosomes capable of pairing in diploid hybrids[8], so that this complete group can be regarded as a single pool from which genes may be extracted and incorporated on wheat chromosomes by recombination. This process will be limited only by the capacity to make appropriate crosses and to devise means of handling the hybrid material. Numbers of manipulations of 27-chromosome material are possible. Hybrids may be back-crossed directly with wheat, or may be treated with colchicine to produce 54-chromosome, multivalent-forming amphiploids also to be used in back-crossing. These amphiploids may be infertile and hard to maintain, and it will then be necessary to use the amphiploid sectors on the original *F*1 plants treated with colchicine for back-crossing.

Similar techniques may be used to exploit the pairing which can be induced between rye chromosomes and wheat chromosomes. Consequently it may, at last, be possible to combine rye and wheat without resorting to breeding amphiploids or whole chromosome addition and substitution lines. The complications to be overcome in handling the derivatives of nulli-V hybrids should not be under-estimated. Nevertheless the exploitation of these hybrids holds unique possibilities for extending the genetic variation of wheat, although a full estimate of the potentialities must be deferred until genetical results are available.

ABSCISSION-ACCELERATORS IN LUPINS (*LUPINUS LUTEUS* L.)

By R. F. M. VAN STEVENINCK*

Crop Research Division, Department of Scientific and Industrial Research, Christchurch, New Zealand

In nearly all recent publications the initiation of abscission is considered to be primarily controlled by auxin[1–4]. Osborne[5,6], however, was the first to publish evidence that an abscission-accelerating factor other than auxin is produced in senescent leaves or with induced senescence of normal green leaves. This natural abscission factor was found to counteract the abscission-delaying effect of indolylacetic acid in bean explants and was claimed not to be a sugar, amino-acid, purine or pyrimidine.

Recently, it was found in our laboratory that a natural abscission-accelerator is produced not only in senescent organs, but also in the rapidly growing fruits of lupins (*Lupinus luteus* L. var. Weiko II), and that this abscission-accelerator has a very powerful inhibiting effect on the growth of wheat coleoptile sections as well.

Young pods were collected seven days after flowering, when they were quite small (mean weight 135 mgm.), but had just entered their period of rapid growth, and were most active in inducing abscission

* Present address: Department of Botany, King's College, London.

of further flowers[7]. The purification of ether extracts, chromatography and coleoptile straight-growth test were the same as reported recently[8]. The results of one chromatogram of the acid fraction of such an extract are illustrated in Fig. 1, and this shows the presence of one growth promotor (A) ($R_F = 0{\cdot}4$–$0{\cdot}5$), and of one powerful inhibitor (B) ($R_F = 0{\cdot}55$–$0{\cdot}75$; solvent isopropanol : 25 per cent ammonia : water = 8 : 1 : 1).

Although B caused up to 90 per cent inhibition of coleoptile extension (the residual growth occurred mainly during the 2-hr. soaking period of the cut sections), it did not appear to have a toxic effect, the sections did not change colour, remained fully turgid, and were capable of assuming growth at a rapid rate after rinsing them in distilled water and adding indolylacetic acid to the medium. Yet, the activity of B in lupin pods was 1,000 times greater than that of inhibitor β from an equal amount of etiolated pea seedlings extracted under identical conditions[8].

Interactions between various concentrations of B and indolylacetic acid were measured, and some of the results in Fig. 2 show that the effect of B can be counteracted by certain concentrations of indolylacetic acid, amounts of 1 and 3 μgm. indolylacetic acid per ml. being able to neutralize the inhibiting effect of B extracted from 230 and 700 mgm. of tissue, respectively.

A and B were extracted separately from their corresponding areas on the chromatograms, to test their activity in the lupin abscission test, which essentially was an adaptation of Addicott's bean abscission test[9]. The explants used in our test consisted of a 2-cm. section of the main flower stalk with the five pedicels half way, and the flowers removed. Directly after cutting, the explants were placed upright in 5-mm. thickness of 2 per cent agar, which was allowed to set in 9-cm. crystallizing dishes, covered by a Petri dish lid. The purified extracts were reduced in volume and applied to punched paper disks in a wide range of concentrations, or they were mixed with small quantities of lanolin paste, which were then applied to the explant, either to one of the proximal sides (the physiological base of the flower stalk, because substances were preferably translocated in apical direction), or to the distal side of the abscission zone (cut end of the pedicel).

Results in Table 1 show that with proximal application abscission is accelerated by both substances

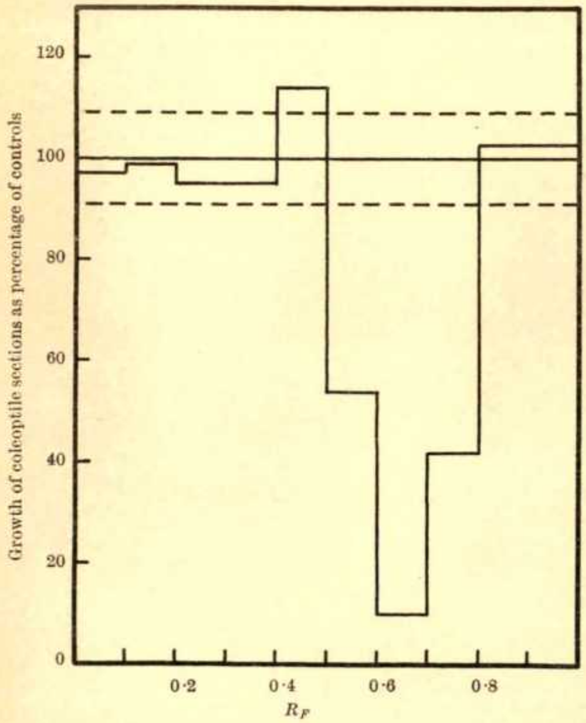

Fig. 1. The response of wheat coleoptile sections to chromatogram strips prepared from the acid fraction of an extract of 10 gm. of lupin pods. Solvent, isopropanol : ammonia 25 per cent : water (8 : 1 : 1). Growth plotted as a percentage of growth of control sections (8·41 mm. over a period of 17½ hr.). The broken line represents the level at which differences were significant ($P = 0{\cdot}05$)

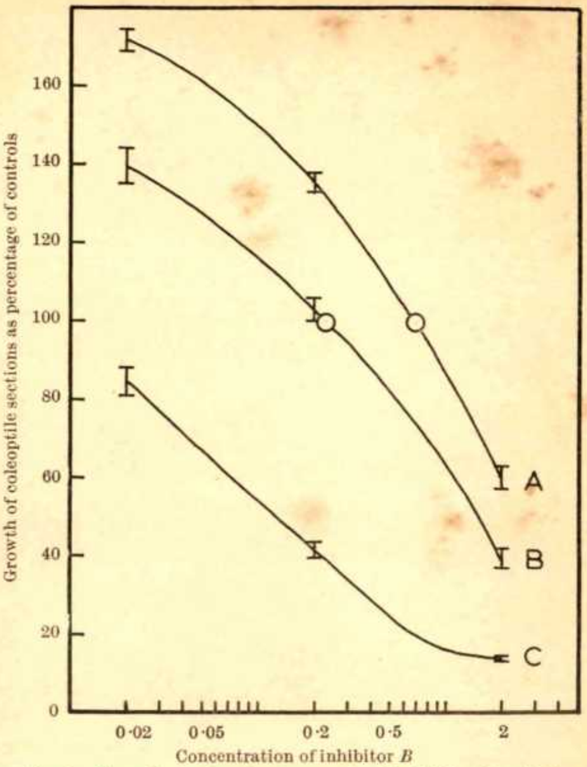

Fig. 2. The effects of various amounts of indolylacetic acid in alleviating the growth inhibition caused by various amounts of inhibitor B (all quantities per 1 ml. medium; vertical lines, 2 × standard error). Curve A, 3 μgm. of indolylacetic acid; B, 1 μgm. of indolylacetic acid; C, no indolylacetic acid added. Abscissa, the equivalent fresh weight of tissue (gm.) from which inhibitor B was extracted

Table 1. EFFECT OF TWO ENDOGENOUS GROWTH SUBSTANCES IN LUPINS ON THE NUMBER OF HOURS REQUIRED FOR 50 PER CENT AND COMPLETE ABSCISSION, RESPECTIVELY

	Hr. to 50 per cent abscission	Hr. to complete abscission
Proximal application		
Control	81·4	115
Inhibitor *B* equivalent to 5 gm. of tissue	64·5	84·5
Inhibitor *B* equivalent to 1 gm. of tissue	81·9	97·5
Promotor *A* equivalent to 5 gm. of tissue	74·9	93·5
Promotor *A* equivalent to 1 gm. of tissue	81·1	100
Distal application		
Control	87·2	134
Inhibitor *B* equivalent to 250 mgm. of tissue	72·0	89
Promotor *A* equivalent to 500 mgm. of tissue	130·5	—

A and *B*. With distal application, however, *B* accelerated abscission and *A* delayed it. Thus, *A* behaved like a true auxin as in Addicott's auxin-gradient theory[1], and *B* like the abscission-accelerating factor extracted by Osborne from senescent leaves.

It was concluded previously that the abscission-inducing effect of developing pods on subsequent flowers could not be explained in terms of auxin only[10]. At present, it appears likely that flowers on basal whorls, which are first to open, are capable of producing pods because, both substances being produced distally to the abscission zone, *A* will counteract the abscission-accelerating effect of *B*. However, once both substances have entered the flower stalk, they are preferentially translocated in the apical direction, and being proximal to the abscission zones, they both would be expected to co-operate in accelerating abscission of further flowers.

Further details of this work, and of comparisons made between virus-infected (low incidence of abscission) and healthy plants, and of changes occurring during the development of pods will be reported elsewhere.

'CHLORIDE-SECRETORY' CELLS IN THE GILLS OF TELEOSTS

By GWYNETH PARRY

Ministry of Agriculture, Fisheries and Food, Freshwater Fisheries Laboratory, 10 Whitehall Place, London, S.W.1

AND

F. G. T. HOLLIDAY and J. H. S. BLAXTER

Marine Laboratory, Aberdeen

CURRENT theories concerning the regulation of water and salts by teleost fishes involve the hypothesis that some ions, principally chloride, are transported against the concentration gradient into a freshwater fish and out of a marine fish. The ability of certain acidophil cells in the gills to bring about this ion movement has come to be generally accepted, although the original claim for this function of the acidophil cells[1] has been contested more than once. Keys and Willmer described the undeniable existence of large numbers of secretory cells in the gills of eels and other teleosts (Fig. 1: all sections were stained with hæmatoxylin-eosin and alcian blue). They estimated that there were between 3 and 6 million cells in an eel weighing 250 gm. and that they constituted "a probable and even possible histological basis for branchial chloride excretion" which had previously been demonstrated[2,3]. The elasmobranch *Scyliorhinus* was found to lack these cells in the gills, which accorded well with the interpretation of osmoregulation in these fish. Experimental evidence for a salt-regulating function for the cells was put forward by Liu[4], who found that their development was favoured by a gradually increasing salt concentration.

Observations on the estuarine mudfish *Fundulus* gave support to the 'Keys-Willmer' theory[5,6], and Getman[7] similarly found differences between secretory and absorptive phases of the cells in the eel. Copeland and Pettengill[8] together demonstrated that enzymic activity could be localized within the cells, thus providing a possible physiological mechanism for chloride exchange.

More recently, Vickers[9] has suggested that the cells represent a metaphasic form of mucous cells. The gradual acclimatization of fish to high external salinities induced the development of the cells. Histological changes were associated with the secretory phase. A large amount of circumstantial evidence has thus been accumulated in favour of a chloride-secretory function.

There has also been some criticism of the 'Keys-Willmer' theory. Krogh[10] was sceptical of a chloride-secretory function of the cells and the absence of any direct evidence justifies this. Bevelander[11] made a comparative study of many fish and suggested that the 'chloride-secretory' cell was a mucous cell. The work of Copeland and Pettengill on *Fundulus* to some extent discredited Bevelander's study; but it is interesting to recall it in the light of Vickers's more recent conclusions. Bevelander found the acidophil cells in the mucous membranes of the mouth and gill cavities, and their presence in the general buccal-branchial region was confirmed in *Fundulus*[12]. Investigations of the acidophil cells in teleosts have demonstrated that their greatest development is in the pseudobranch[13] (Figs. 1–3). The pseudobranch, whether it is represented by the simple gill-like structure in the herring, or the more complex enclosed mass in the salmon, consists of large acidophil cells held compactly by connective tissue, with a well-developed capillary blood supply. This picture is essentially the same in marine, freshwater or

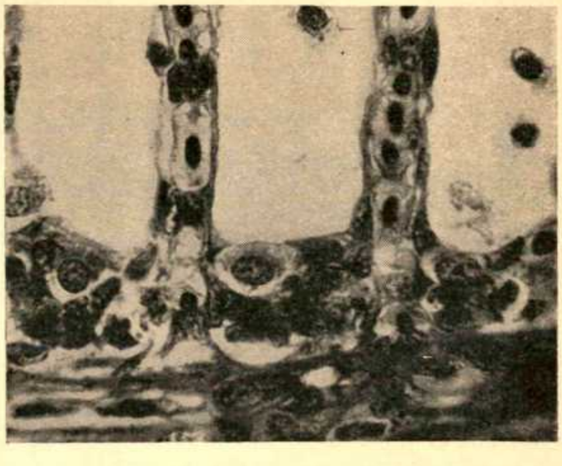

Fig. 1. Photomicrograph of T.S. gill lamellæ of salmon smolt in fresh water to show detail of acidophil cells. (× *c.* 700)

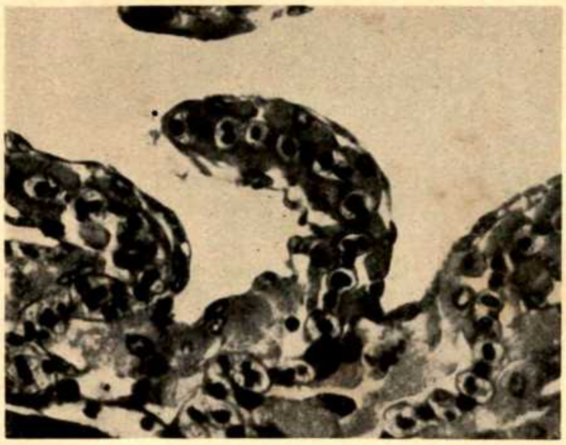

Fig. 2. Photomicrograph of T.S. pseudobranch of young herring in sea water. (× *c.* 600)

migratory species. The acidophils of both gills and pseudobranch are regarded as the same cells[13]; if their identity is established, then it is important to reconsider their function.

The presence of similar acidophil cells in both freshwater and marine teleosts presents another aspect of the problem. Some of the authors quoted have seen histological changes, and attributed them to changes in the polarity of the cells, when the fish are living in different environments. The presence of the cells in regions where they could not function as chloride regulators and their apparent absence in newly hatched fish larvæ, where regulation takes place, also create doubts as to the general validity of the theory. The anatomical disposition of the pseudobranch, for example, is such that the blood supply is from the first efferent gill artery; within the pseudobranch it becomes a capillary network; and after anastomosis it goes principally as an ophthalmic artery to the eye. Thus, the blood reaching the pseudobranch has already passed the respiratory and ion-regulating gills. It must be fully oxygenated, with no appreciable load of bicarbonate which could be broken down by the carbonic anhydrase present. The acidophil cells of the pseudobranch and other parts of the branchial region thus have a very different internal environment from those in the gills. In addition, while the pseudobranch hangs freely into the branchial cavity in a few teleosts, in many it has sunk below the epidermal surface.

Experiments designed to investigate the function of the pseudobranch in some teleost fishes are in progress and are being conducted along two lines:

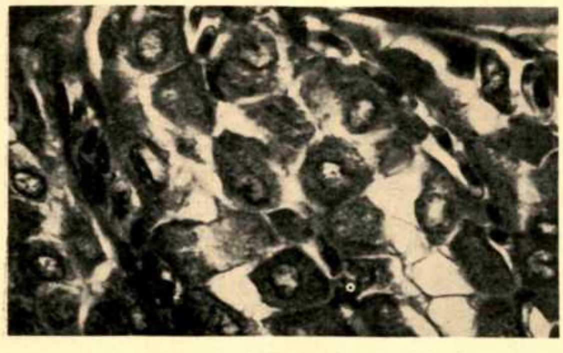

Fig. 3. Photomicrograph of T.S. pseudobranch of salmon smolt in fresh water. (× *c.* 600)

(1) The osmoregulatory ability of bilaterally pseudobranchectomized fish and normal fish in different salinities is being compared.

(2) The rate of ion transport in operated and normal fish is being compared, using radio-isotopes.

Preliminary results do not suggest that the pseudobranch is a major site of osmoregulation within the range of salinities 0–3·5 per cent. In a number of species (herring, saithe, sea trout, rainbow trout) the pseudobranch can be removed on both sides either by heat cautery or by a surgical technique. No significant difference in survival-times could be found between those sea water fish replaced in sea water or in isotonic medium ($\frac{1}{3}$ sea water), freshwater fish replaced in fresh water, and controls. All species of fish were seen to feed within a day or two of the operation; there were no external signs of distress. The majority of the fish are still alive some 2–3 months after the operation, and no increase in the acidophils of the gills of these fish has been observed (Fig. 4).

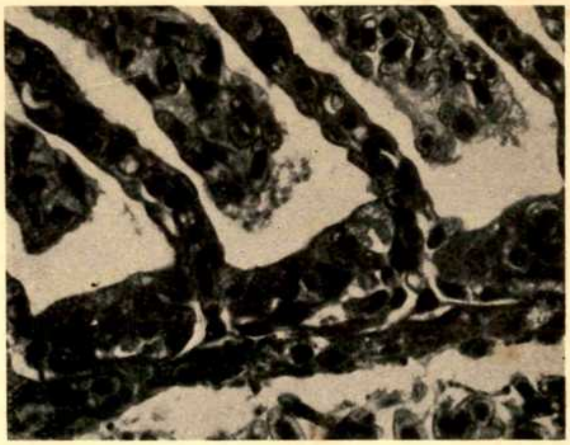

Fig. 4. Photomicrograph of T.S. gill lamellæ of adult sea trout in sea water three months after pseudobranchectomy. (× *c.* 600)

Since the fish appear to achieve osmoregulation in fresh water or sea water after pseudobranchectomy, should we conclude that the cells of the gills alone are able to cope with osmotic stresses of the magnitude?

If the cells of the pseudobranch do not function as chloride-regulators, we are justified, in the absence of any direct evidence, in asking if the very similar cells of the gills do act in this way. In short, are the acidophils of both gills and pseudobranch concerned with salt-exchange at all? It is hoped that a more complete investigation of the function of the pseudobranch will help to answer this question.

PHYSICAL SCIENCES

A High-resolution Survey of the Andromeda Nebula at 408 Mc./s.

In December 1958 observations of the Andromeda Nebula were made using the 250-ft. radio telescope at Jodrell Bank[1]. A Dicke type radiometer, pass-band 408 ± 2 Mc./s., noise figure 6 db., was used. The beam was elliptical, having half-power widths of 40 and 56 min. of arc. The system was calibrated using radio source 14*N*5*A*, which was assumed to have a flux[2] of 47×10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$. Figs. 1, 2 and 3 show the intensity contours of the nebula, averaged scans along the major and minor axes, and an actual record of a scan through the nebula.

Previous lower-resolution surveys at 158 Mc./s. and 237 Mc./s. have shown[3,4] that the radio emission from the nebula can be divided into two components, one co-extensive with the visible nebula called the disk component, and accounting for 10 per cent of the total emission, and the other a much broader elliptical component, called the corona, extending over 10° along the major axis and 6° along the minor axis.

The outstanding new feature shown by this high-resolution survey is the complex structure of the corona, in particular the spur-like extensions away from the major axis (Fig. 1). Some structure is also seen in the radiation from the disk component. The greater part of the radio emission from the disk lies above the dotted line on the minor axis scan (Fig. 2) and appears to come from a source coincident with the optical centre. This peak is not broader than the beam, so that an upper limit of 35 min. of arc can be set for the diameter of this central source of radiation. At the points marked by arrows on the major-axis scan in Fig. 2, the profiles of optical and radio emission both show a change of slope. It is interesting to note that this is the brightest part of the spiral-arm structure of the nebula.

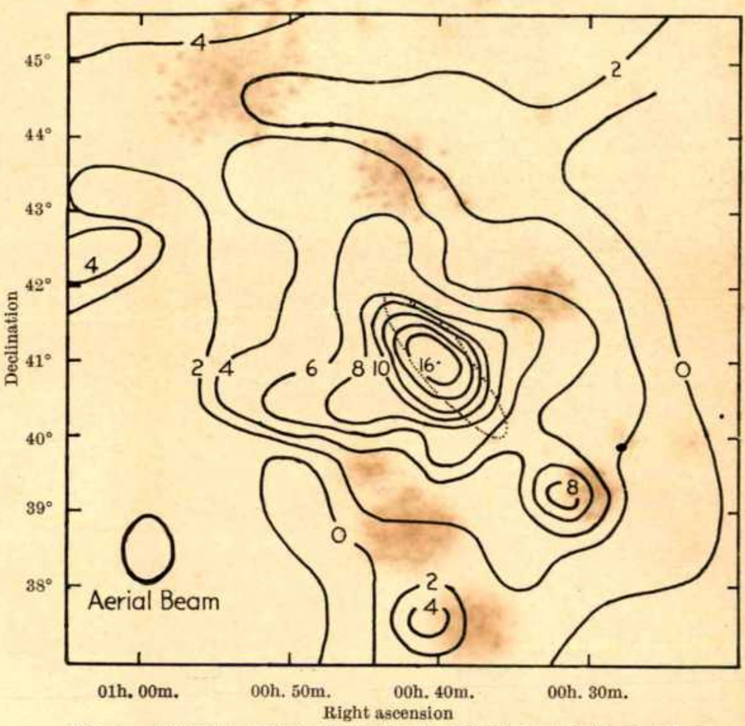

Fig. 1. 408 Mc./s. radio contours of the Andromeda Nebula plotted in intervals of 2 deg. K. brightness temperature, indicating the temperature above a chosen reference region, R.A. 00h. 15m., dec. + 38°. The dotted ellipse shows the 24·05 mag.²/sec.² contour taken from a recent photometric survey by de Vaucouleurs (ref. 8) of the nebula. The co-ordinates are for epoch 1950.0

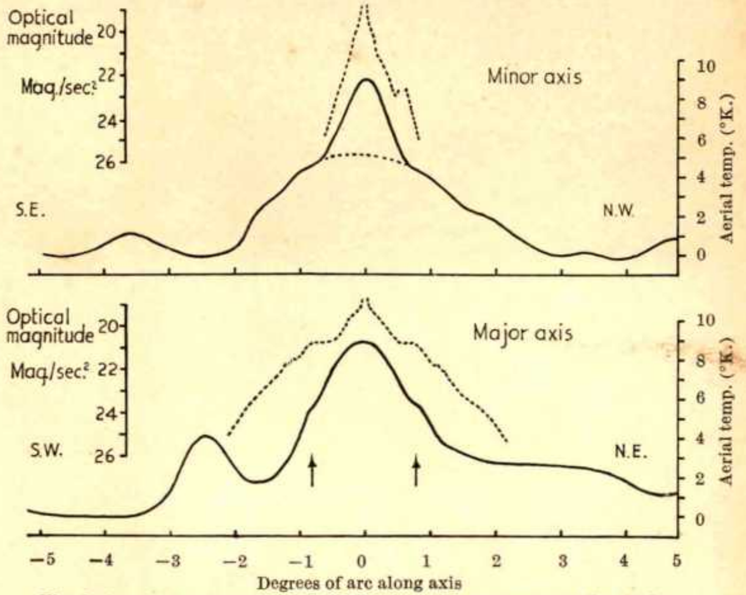

Fig. 2. Averaged radio scans along the major and minor axes of the Andromeda Nebula. In each case the major axis of the beam lay within a few degrees of the major axis of the nebula. The dotted curves are the corresponding photometric profiles obtained by de Vaucouleurs (ref. 8)

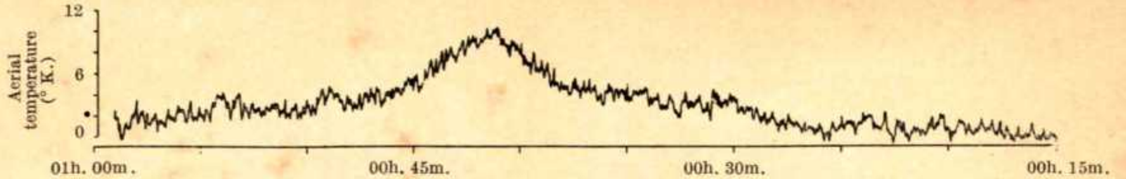

Fig. 3. A typical drift curve through the Andromeda Nebula at + 40° 15′ declination

Assuming that the corona extends to the 2° K. contour (Fig. 1) the total emissivity is 140×10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$, of which the disk component contributes 8×10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$. The general background temperature has been assumed to be 1 deg. K. above the reference temperature, and this has been subtracted before measuring the emissivity. The extended 'plateau' to the north of the nebula has been included, although it is not certain that it is associated with the nebula.

The radio sources (R.A. 00h. 31m. 45s., dec. + 39° 12′, flux $4 \cdot 5 \times 10^{-26}$ W.m.$^{-2}$ (c./s.)$^{-1}$; R.A. 00h. 34m. 30s., dec. + 38° 24′, flux $1 \cdot 5 \times 10^{-26}$ W.m.$^{-2}$ (c./s.)$^{-1}$) have been assumed not to lie in the nebula, and their emissions have been subtracted in deriving the figure for the total emissivity. The source (R.A. 00h. 40m. 30s., dec. + 37° 36′) lies outside the assumed limits of the corona. It has a flux of 3×10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$.

The fainter satellite of Andromeda, N.G.C. 205 (R.A. 00h. 37m. 40s., dec. + 41° 25′), is an irregular elliptical galaxy (E_5, $m_p = 8 \cdot 9$)[5]. No radio emission has yet been detected from an elliptical galaxy or any similar structure (for example, a globular cluster) devoid of interstellar gas[6]. It is important to decide how much elliptical galaxies radiate relative to normal spiral galaxies, so that the importance of interstellar gas in the production of radio radiation may be assessed. An upper limit of 2×10^{-26} W.m.$^{-2}$ (c./s.)$^{-1}$ may be placed on the flux from N.G.C. 205 at 408 Mc./s., by examination of the contours in Fig. 1. This is less than 70 per cent of the radiation from a normal spiral galaxy having the same photographic magnitude. This calculation is based on a value given by Hanbury Brown and Hazard (private communication) for 158 Mc./s. radiation, that $m_r - m_p$ is equal to $0 \cdot 5$ for normal S_b galaxies, if m_r is defined as $m_r = - 53 \cdot 45 - 2 \cdot 5 \log S_{158}$. The spectral index is taken to be $- 1 \cdot 1$.

The nature of the spur-like extensions of the contours (Fig. 1) is at present a matter for speculation. In the left-hand spur, some indication of fine structure is seen in the original records. The records show two sources of a few flux units at positions R.A. 00h. 46m. 15s., dec. + 40° 24′ and R.A. 00h. 52m. 00s., dec. + 40° 30′. If these sources are subtracted, the spurs then appear symmetrical. Similar north and south polar spurs have been detected in the radio emission from our own Galaxy[7], and although they are not as prominent as the spurs in Andromeda, it is possible that such spurs are structural features common to spiral galaxies. In Andromeda, the angle made by the line of extension of the spurs to the minor axis is what would be expected if the synchrotron mechanism[9] were responsible for the emission. This suggests that the magnetic fields in the corona of the nebula may be ordered, and related to the spiral arm structure.

We thank Prof. A. C. B. Lovell for making available the facilities at Jodrell Bank, and Mr. R. Hanbury Brown and Dr. C. Hazard for suggestions and criticisms throughout the course of the work. One of us (D. S. M.) gratefully acknowledges a Leverhulme Research Fellowship.

Fine Iron Filaments Magnets

It has been known for many years that a body containing parallel elongated and suitably equispaced iron particles, each of about $0 \cdot 02 \mu$ cross-sectional diameter, should theoretically possess excellent permanent magnetic properties. To the best of our knowledge, all attempts at producing materials with the desired structure have relied on the manufacture and compacting of submicroscopic iron particles. Although the results have been of considerable scientific and commercial interest, the desired degree of uniformity of particle characteristics has not yet been achieved.

In an endeavour to avoid some drawbacks of previous methods, we have developed a technique of drawing compacts containing parallel iron wires embedded in a copper alloy matrix until the iron wires become invisible filaments and the compacts acquire a high intrinsic coercive force. Values of 300–700 oersteds have been obtained so far. (Patent applications have been filed in Australia and overseas countries in respect of these methods and materials.)

Provided the materials within the compacts and the reducing methods are suitably selected, it is possible to preserve a fair uniformity of the iron cross-sections and spacings until the filaments are a few microns in diameter. Below the limit of optical microscopic resolution, magnetic measurements suggest that the iron filaments are excellently aligned and that some of them satisfy the theoretical requirements even when their estimated equivalent diameter is smaller than $0 \cdot 1 \mu$.

Fig. 1 shows the median intrinsic coercive forces of the individual filaments at infinite spacing, estimated from magnetic measurements of the best compacts produced so far. These results have been obtained only in very fine brittle wires drawn under conditions of extreme cold work and then annealed. More ductile compacts, allowing further reductions, have generally produced lower

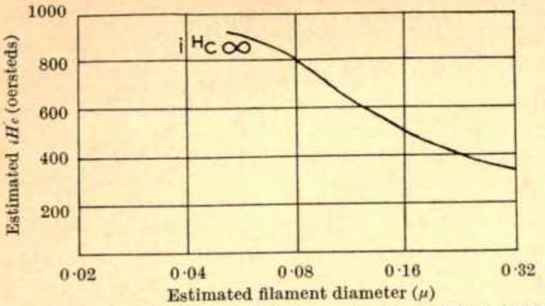

Fig. 1. Estimated median intrinsic coercive force of the individual filaments at infinite spacing versus estimated filament cross-sectional diameter

coercive forces at any given estimated equivalent filament diameter.

Members of the staff of the Division of Tribophysics of the Commonwealth Scientific and Industrial Research Organization have greatly contributed to the success of this preliminary investigation. Thanks are also due to the British Iron and Steel Research Association for supplying a sample of very pure iron wire.

Sintering of Quartz Crystal

The transformation of quartz into cristobalite at temperatures higher than 1,470° C. has hitherto been accepted as a direct process. Recent measurements of the kinetics of this reaction (unpublished work) have, however, shown that the process is indirect and consists of two consecutive reactions in which a non-crystalline, disordered silica phase appears as an unstable intermediary between the quartz and the cristobalite.

During this work, quartz particles heated at 1,500–1,570° C. were observed to sinter in the early stages of the reaction so strongly as to convert the original loose powder to a hard mass and to reduce the rate of reaction substantially. This effect occurred before any cristobalite had developed and ceased once cristobalite became abundant, when the mass reverted to powder. The purity of the quartz used (Brazilian crystal) ruled out the possibility of any fluid phase except from the quartz itself. It therefore seemed likely that the intermediate non-crystalline phase was responsible for the sintering.

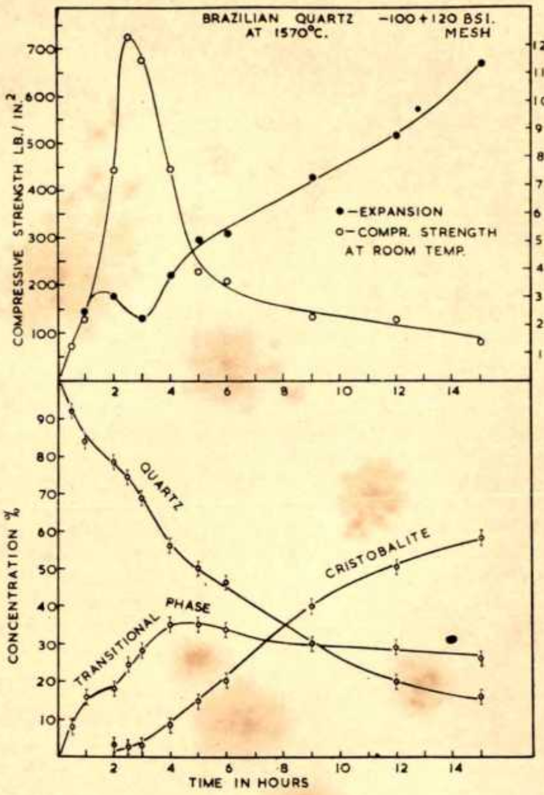

Fig. 1

These effects were studied further by measuring the compressive strength and the linear expansion or contraction, both at room temperature, of pressed cylindrical specimens after firing for various periods at 1,500°, 1,530° and 1,570° C. The results for Brazilian quartz crystal (average diameter 0·137 mm.) at 1,570° C. are shown in Fig. 1. The mineralogical constitution of each sample was determined by differential thermal analysis, which is now established as a reliable method for this purpose[1].

It will be seen that, in the early stages of the reaction, the quartz was transformed solely into the intermediate phase; at the same time, the compressive strength rose rapidly and shrinkage took place. Following the appearance of appreciable

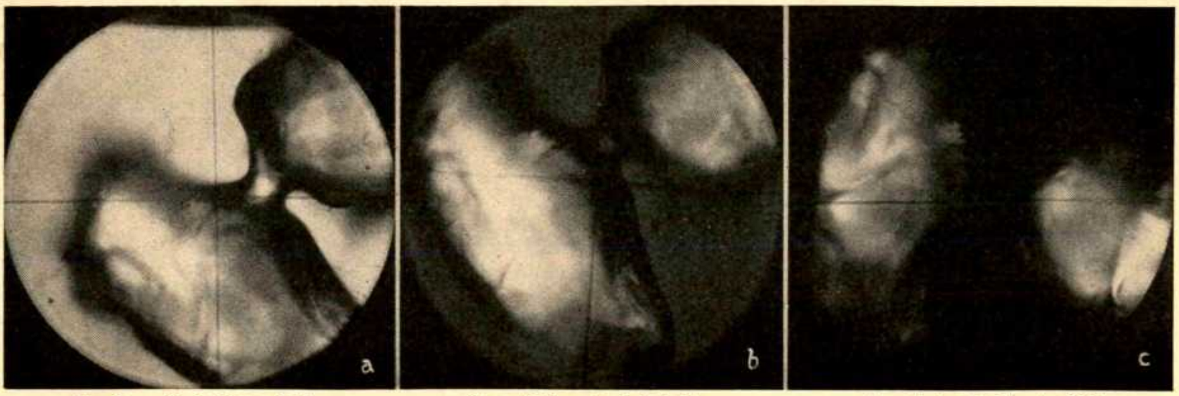

Fig. 2. (*a*) Ordinary light; (*b*) partially polarized light; (*c*) polarized light. (× 200)

amounts of cristobalite (namely, after 3–4 hr.), the strength diminished rapidly; expansion again occurred as the result of the continued conversion of quartz into forms of lower density.

Sintering and shrinkage of pure oxides at high temperatures are usually attributed to diffusion and the formation of 'necks' or lenses at points of contact between the particles. Examination of the quartz under the microscope showed that this mechanism was operative. Fig. 2 illustrates typical examples of the abundant neck-growth found after firing for 2½ hr., when about 20 per cent of the intermediate phase and virtually no cristobalite had developed. Fig. 2*a* is in ordinary light; Figs. 2*b* and 2*c*, in polarized light with partial and total extinction respectively, clearly indicate the intermediate phase as a continuous isotropic layer surrounding the residue of the quartz crystal and forming the neck between the particles. Sintering in quartz thus appears to take place via the disordered surface layer developed at high temperatures and is not inherent in the crystal. The rapid drop in strength on continued heating suggests that cristobalite is similarly deficient in sintering characteristics at the temperatures used. Full details of this work will be published shortly.

This work is part of a programme made possible by the award of an 1851 Senior Studentship to one of us (A. C. D. C.), and we thank the Royal Commission for its support.

CHEMISTRY

Ionization Potentials of Electron Donors

Recently, Briegleb and Czekalla[1] have described a method of determining the ionization potentials (I_p) of electron donors from the frequencies (ν) of the charge-transfer bands of the complexes of these donors with certain electron acceptors. This is based on a non-linear theoretical relationship between I_p and ν.

Similar results may be obtained from an empirical linear relationship between I_p and ν; this is sufficient to correlate the experimental values of I_p and ν. Such relationships have been determined for complexes of donors of reliably known ionization potential[2] (namely, benzene, toluene, *m*-xylene, mesitylene, naphthalene, 1-methylnaphthalene and aniline) with the electron acceptors chloranil (C), *p*-benzoquinone (Q) and 1,3,5-trinitrobenzene (T) respectively. These are:

$$I_p = 5{\cdot}13 + 1{\cdot}39 \times 10^{-4}\ \nu_C$$
$$I_p = 4{\cdot}61 + 1{\cdot}33 \times 10^{-4}\ \nu_Q$$
$$I_p = 4{\cdot}25 + 1{\cdot}39 \times 10^{-4}\ \nu_T$$

for solutions in carbon tetrachloride, where I_p is in electron volts, ν in cm.$^{-1}$, and the subscripts to ν indicate the appropriate electron acceptor.

From measurements of frequencies of charge-transfer bands of complexes of these three acceptors with other donors in carbon tetrachloride, the ionization potentials may be evaluated. Examples are quoted in Table 1.

Table 1

Donor	Ionization potential (eV.)				
	Calc. from ν_C	Calc. from ν_Q	Calc. from ν_T	Mean	Ref. 1
Durene	8·0	8·2	8·3	8·2	8·4
Pentamethylbenzene	7·9	7·9	7·9	7·9	—
Hexamethylbenzene	7·8	7·8	7·8	7·8	7·9
Anthracene	7·4	7·4	7·4	7·4	7·4
N,N-Dimethylaniline	7·3	7·3	7·1	7·2	—
N,N,N',N'-Tetramethyl-*p*-*p*'-diaminodiphenylmethane	7·1	7·0	7·1	7·1	—
N,N,N',N'-Tetramethyl-*p*-phenylenediamine	6·7	6·7	6·7	6·7	—

For aromatic electron donor molecules, save those of very low ionization potential where it is improbable that such relationships are justified, this method may provide a simple means of estimating ionization potentials which may be difficult to determine by other methods, such as Rydberg series, photo-ionization and electron impact, because of practical details such as the low vapour pressure of some of these substances.

Radioassay of Aqueous Solutions mixed with Solid Crystalline Fluors

I have previously described a new approach to direct radioassay of aqueous solutions of weak beta-ray emitting isotopes in the liquid scintillation spectrometer[1]. The aqueous solution was intimately mixed with a mass of finely divided beads of clear plastic into which a fluor (diphenylstilbene) has been incorporated (Pilot *B*-Beads, Pilot Chemicals, Inc., Watertown, Mass.). We wish to report that a number of crystalline fluors, more efficient, less expensive and more generally available, can be substituted for the plastic and used in an analogous fashion despite their poorer light-transmitting qualities[2]. For example, in a slurry made up of 0·7 ml. $Na_2{}^{14}CO_3$ and 0·5 gm. diphenyloxazole the carbon-14 was counted with 27 per cent efficiency. Instead of trying to hold the solid fluor in stable suspension, which can be done with the help of thickeners such as glycerol, it has proved more satisfactory to let the fluor settle to the bottom of the vial. Addition of a detergent is essential to ensure prompt and uniform wetting of the crystals. The performance of a fluor depends not only on its inherent fluorescence efficiency but also on the size and shape of the crystals, since the closeness of packing determines the mean free path of beta-particles through the solution before they encounter a fluor crystal. Best results thus far have been obtained using blue-violet fluorescence-grade anthracene crystals (Distillation Products Industries, Rochester, N.Y.). This highly purified material was three times as efficient as ordinary 'chemically pure' anthracene. The difference may in part reflect the presence of trace impurities in the latter, known to shift the fluorescence to higher wave-lengths. Even different lots of fluorescence-grade anthracene may differ by 20–30 per cent in efficiency, but the material in any given lot gave excellent reproducibility without further treatment. A routine technique currently used in our laboratories for carbon-14 and tritium is described.

Exactly 1 gm. of anthracene is weighed into a ·5-dram counting bottle (T. C. Wheaton Co., Millville, N.J.), 3 ml. of the unknown solution (containing 1 : 1,000 'Triton *GR*-5', Rhom and Haas Co., Philadelphia, Pa.) is pipetted on to the mass of anthracene and the mixture is stirred, breaking up any clumps of crystals. After an hour to allow the crystals to settle completely, the vial is ready for counting. The count-rate does not appear to be sensitive to temperature in the range 0–25° C., but freezing can alter the count-rate, depending on the extent to which radioactive solute becomes concentrated adjacent to the crystals during freezing. Counting in the present study was done in the Packard liquid scintillation spectrometer with a box temperature of approximately 2° C., photomultiplier voltage 1,345 V. (tap 10) and 'window' setting 10–∞. Under these conditions absolute efficiency for carbon-14 in 3 ml. of solution is 20 per cent; for tritium, 0·5 per cent. Background-rate is 90–110 c.p.m. At 1,200 V. background is only 65 c.p.m. and efficiency is only 10 per cent less than it is at 1,345 V.

As shown in Fig. 1 smaller volumes added to the 1 gm. of anthracene are counted with considerably higher efficiency (maximum of 54 per cent for carbon-14, 2·3 per cent for tritium when only the crystals at the top are wetted) but reproducibility is less satisfactory and quenching correction with internal standard cannot be easily made. Above 3 ml. sample volume, further addition of a sample of the same specific radioactivity in c.p.m./ml. does not further increase the observed count-rate. Reproducibility of the routine method is shown by replicate analyses of an aqueous solution of alanine-1-^{14}C, which gave standard deviations of 3·6 per cent (7 samples) and 4·1 per cent (5 samples). Three sets of four replicate samples of tritiated water were counted with a maximum range of ± 3·5 per cent. Quenching due to materials with absorption spectra overlapping the emission spectrum of anthracene is corrected for by adding an internal standard of the appropriate isotope in a volume of 0·05 ml., stirring and recounting. The validity of such a quenching correction is shown by the results in Fig. 2.

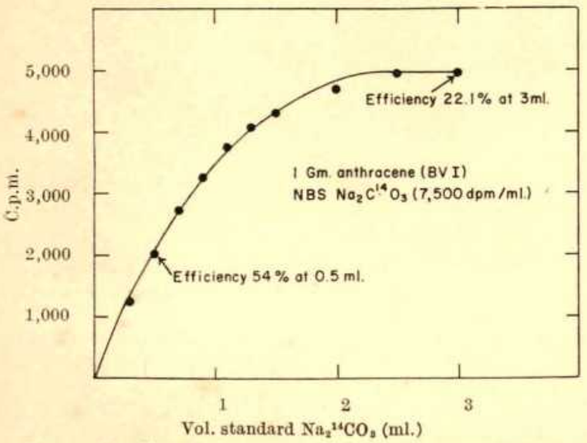

Fig. 1. Counting efficiency as a function of volume of solution added to a fixed amount of anthracene

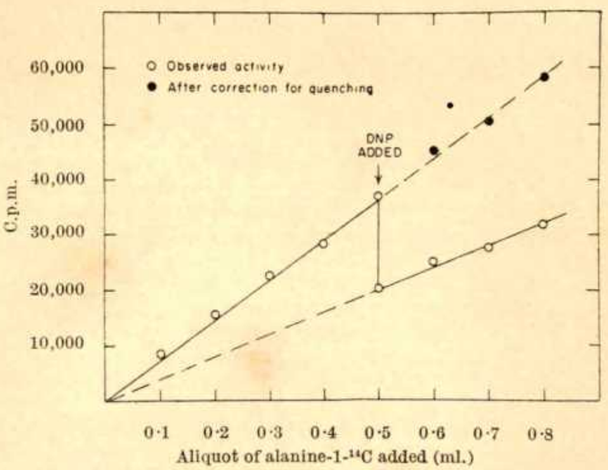

Fig. 2. Correction for quenching. The indicated aliquots of alanine-1-^{14}C were added to a vial containing 1 gm. of anthracene and 12 ml. of water containing 1 : 1,000 'Triton'. 2,4-Dinitrophenol was added at the point indicated

The method has been successfully applied to solutions of proteins, glucose, amino-acids and sodium carbonate in water or in buffer and to proteins and sodium carbonate in sodium hydroxide. It should be applicable to any material soluble in aqueous solvents and not reacting with anthracene. It has been shown that small molecules such as sodium carbonate, glucose and amino-acids can be quantitatively recovered by washing the anthracene. This feature of the method may be particularly valuable when only small amounts of sample are available and a radioassay is desired prior to further studies. Another important application of the method is in the counting of material of low specific activity when large amounts are available. If the material does not quench the fluorescence, it may be concentrated to high levels so that many milligrams are counted at the indicated efficiency. Larger amounts of anthracene have also been used (for example, 12 ml. of solution with 6 gm. anthracene) and even though the efficiency does not go up linearly (a large fraction of the emitted light comes from the upper surface of the anthracene mass) this permits considerably higher absolute count-rates. It may make feasible the counting of polar compounds with specific radioactivity too low to count in the conventional liquid scintillation systems, considering the limitations in sizes of sample sometimes involved.

Derivatographic Investigation of the Anthracite of the Don

The anthracite of the Don has been investigated by the derivatographic method of F. Paulik, J. Paulik and L. Erdey[1]. By this method it is possible, by a single, automatically recorded measuring process, to obtain not only the thermogravimetric curve showing the change in weight of the sample (*TG* in Fig. 1) but also the rate of loss of weight (*DTG*) and

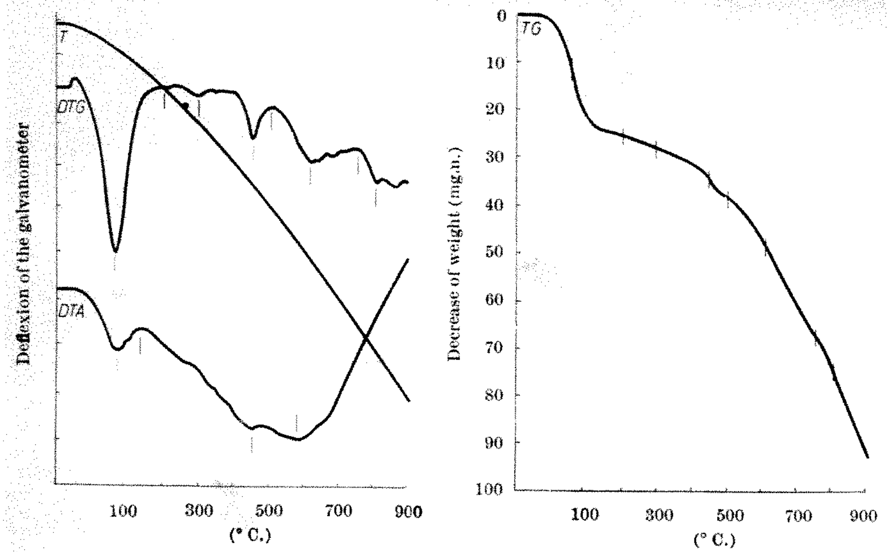

Fig. 1

the differential thermal analysis curve (*DTA*), giving information on the changes in temperature during thermal decomposition. The temperature curve (*T*), with the assistance of a calibration curve previously photographed on the paper, gives the temperature corresponding to each point obtained.

The immediate analysis of Don anthracite is as follows: ash, 9·4 per cent; combustibles, 90·6 per cent; coke, 96·3 per cent; carbon fix, 86·9 per cent; volatiles, 3·7 per cent.

By adjusting the sensibility of the balance, its full-scale deflexion was made to correspond to a change of weight of 100 mgm. A rate of heating of 5 deg. C./min. was maintained from room temperature to 900° C. Experiments were carried out in a stream of nitrogen (15 l./hr.).

The maximum rate of release of water vapour from the sample (water content, 2·5 per cent) occurs at 80° C. An endothermic maximum on the *DTA* curve occurring at 85° C. corresponds to this peak in the release of water. As only a relatively small part of the water is driven off in the temperature-range above 100° C., it appears that water is bound mainly by absorptive forces in the anthracite, chemical forces playing a relatively insignificant part.

A small peak occurs on the *DTG* curve at 295° C. This peak is of great interest, as it shows that atomic groups and structures characteristic of cellulose and plant residues are still conserved—though to a small degree—in anthracite.

In the derivative thermogravimetric study of peats and peat constituents[2], a high peak was reported at 300° C. in the thermal decomposition of cotton cellulose. When projecting the data of the *DTG* curve on the *TG* curve, it can be seen that this characteristic cellulose structure is present in only 0·3 weight per cent in anthracite, presumably in the form of side-chains.

The decomposition peak at 350° C., characteristic of humic acids, does not appear at all on the *DTG* curve of the anthracite.

The next peak of the *DTG* curve occurs at 450° C. This maximum is analogous to the main peak in the decomposition of bituminous coals, the position of which was found to vary between 390° C. and 420° C., according to the quality of the bituminous coal. As the temperature of decomposition is a function of the rank of coal, and the peak of decomposition is shifted towards higher temperatures with higher ranks of coal, it is not unexpected that in the case of anthracite—the last of the series—it should occur at 450° C.

It was found in an earlier investigation, by comparing the results of derivatographic analysis with those of dilatometric tests, that the main peak on the decomposition curve corresponds to the resolidification temperature T_3, that is, to the beginning of coke formation. Although anthracite does not pass into the plastic state through the action of heat, and consequently no resolidification takes place, it can reasonably be supposed, on the analogy of bituminous coals, that the peak exhibited by anthracite at 450° C. also marks the initial temperature of coke formation.

These observations are in good agreement with the X-ray results reported by Lermusiaux and Quinot[3]. They conclude from the radiograph of anthracite that the structure of anthracite contains particles of 5·7 A. radius, consisting of 84 carbon atoms, which are distributed in two layers, spaced at 3·4 A. from one another. The individual particles are linked together by oxygen-bridges.

The evolution of gases, consisting chiefly of carbon monoxide and carbon dioxide, in the temperature range 200–500° C. can be attributed to the rupture of these oxygen bridges. Above 500° C. a substantial change occurs in the radiograph. A structure of 12 carbon atoms characteristic of coke appears. The particles consist of two graphite hexagons, 3·4 A. apart; whereas in coke from bituminous coals the particles are strongly linked by carbon atoms and radicals formed of cracked bitumen, the hexagons in coke from anthracite are not linked together materially.

My derivatographic investigations suggest that coke formation begins at 450° C. This result agrees well with the X-ray results mentioned above, as it is obvious that coke formation must have progressed to a certain degree before the coke structure becomes observable radiographically. Above 500° C. the character of the evolved gases also changes, and the gases released consist chiefly of hydrogen. The appearance of hydrogen may be ascribed to the depolymerization of the 84 carbon-atom structure and the formation of the 12-carbon graphite hexagons:

$$C_{84} \rightarrow 7\,C_{12}$$

The *DTG* and *TG* curves suggest that the structure characteristic of bituminous coals contributes only 0·7 per cent to that of the anthracite, but as it is split off in a relatively limited temperature interval of not more than 100 deg. C., it is easily observable.

The most important quantitative changes in anthracite occur above 500° C. The loss of weight in the range 500–800° C. amounts to 3·5 per cent. The changes in this region, which exhibits a further peak above 600° C., appear to be due to strong depolarization of the anthracite structure.

It should be mentioned that the values for volatiles obtained derivatographically are somewhat higher than those from immediate analysis, probably because of the slower rate of heating.

The *DTA* curves show that the peak at 450° C. analogous to the decomposition peak of bituminous coals, and the decomposition peak above 500° C. characteristic of depolymerization are both endothermic.

Derivatographic results with anthracites from another source may possibly be somewhat different from those obtained for the Don anthracite ; nevertheless, since the structure of different coals becomes more similar with higher rank, great differences are not to be expected in the thermal decomposition of individual anthracites.

MINERALOGY

Variation in Etch Behaviour of Jacobsite with Different Cell Dimensions

During the study of polished sections of manganese ores from the Kodur Group of mines, Srikakulam Dt., Andhra Pradesh, India, I came across three different types of jacobsite, associated with other manganese minerals like braunite, hausmannite, pyrolusite, cryptomelane, coronadite and γ-MnO_2. It is the interesting variation in the colour and etch behaviour in the different types of jacobsite that attracted my attention, and investigations to find out the cause of such variation were attempted.

Of the three different types of jacobsite, one occurs as a homogeneous mineral, pseudomorphous after garnet, whereas the other two types are in widmanstatten intergrowth with hausmannite. Of the last two types, one exhibits all the characters of normal jacobsite as described by Ramdohr[1] and Uytenbogaardt[2]. It is non-pleochroic olive-grey in colour with reflecting power of 19·6 per cent in green light in air, isotropic and negative to all standard reagents. It is the second type of jacobsite in intergrowth with hausmannite that exhibits altogether different colour under reflected light, and its reactions to etch reagents are also different. It is rose-brown in colour with reflecting power of 20·01 per cent in green light in air. It reacts with concentrated hydrochloric acid in 1½ min. and the solution turns greenish-yellow. With hydrofluoric acid, the mineral is instantaneously etched black with corroded surface ; the etching is much faster than in the hausmannite exsolution lamellæ. All these characters are very similar to those exhibited by magnetite, though the mineral was conclusively identified as jacobsite by X-ray powder analysis (Table 1). All the different types of jacobsite yielded similar *d* spacings, though their other characters vary considerably.

To investigate the possible cause of this peculiar etch behaviour of jacobsite, the cell dimension of all the three types was measured and the results are given in Table 2.

Table 1. Measured *d* Spacings and Intensities of Jacobsite. Iron/Manganese Radiation

d (A.)	*I*	*d* (A.)	*I*	*d* (A.)	*I*

Table 2. Cell Dimensions of Jacobsites

Description	Cell dimension
1. Homogeneous jacobsite pseudomorphous after garnet	$a = 8·506$ A.
2. Jacobsite, olive-grey in colour, unetched by any standard reagent, in intergrowth with hausmannite	$a = 8·483$ A.
3. Jacobsite, rose-brown in colour, etched by hydrochloric acid and hydrofluoric acid, in intergrowth with hausmannite	$a = 8·410$ A.

According to Mason[3], the cell dimension of jacobsite increases with increased amounts of manganese in structure. In Table 2, the first type of jacobsite has the largest cell dimension ($a = 8·506$ A.), which, according to Mason's[3] diagram (p. 146), contains a fair amount of manganese in excess of minimum. This excess manganese could not exsolve, apparently due to lack of proper temperature. The second type of jacobsite has all the characters of true jacobsite, and its cell dimension compares favourably with any normal jacobsite in the vredenburgite field. The third type has a much smaller cell dimension ($a = 8·410$ A.), which indicates, according to the experiments of Mason[3], that it approaches the magnetite–jacobsite transition field with about the minimum quantity of manganese in solid solution. It may thus be concluded that, while the mineral has just the structure of jacobsite, the composition tends more to that of magnetite and therefore its reactions to etch reagents conform more to magnetite than to jacobsite. This type of jacobsite with composition approaching the magnetite–jacobsite transition field, and exhibiting corresponding etch behaviour, should not be too uncommon in the metamorphic manganese ores of India, of which jacobsite is an important constituent. It may be that such etch characters were overlooked in earlier investigations.

I acknowledge the facilities I enjoyed in the laboratories of the Department of Geological Sciences,

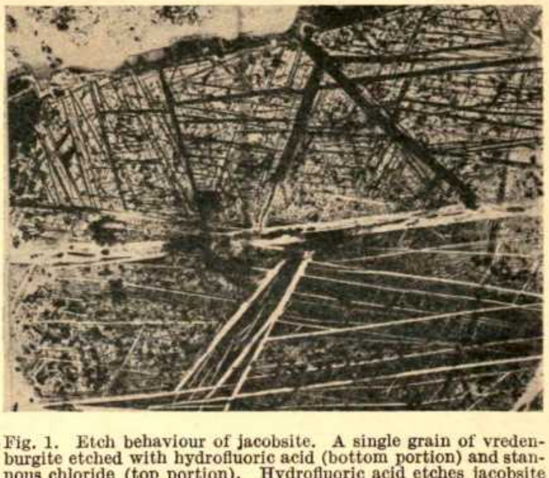

Fig. 1. Etch behaviour of jacobsite. A single grain of vredenburgite etched with hydrofluoric acid (bottom portion) and stannous chloride (top portion). Hydrofluoric acid etches jacobsite sooty black but hausmannite is unaffected. Stannous chloride etches hausmannite but did not attack jacobsite. (× 200)

Jadavpur University, Calcutta, and of the Mineralogy Division, Geological Survey of Canada. I am grateful to Miss J. Trask, of the Geological Survey of Canada, for her help in the X-ray powder analysis of the jacobsites.

The Spinel–Olivine Inversion in Mg_2GeO_4

DURING the past few years there has been active interest in the problem of alternative explanations other than layers of different composition in the Earth to explain seismic data. The most important of these arises from an early suggestion by Bernal[1] regarding the possible inversion of the orthorhombic mineral olivine to a dense form with the spinel structure. An actual example of this inversion from the spinel to the olivine had been reported by Goldschmidt[2] for the compound Mg_2GeO_4. However, there have always been some doubts regarding this observation, since it was mentioned only in a footnote and could not be repeated.

With the revived interest, there have apparently been several attempts[3] to synthesize the spinel form of Mg_2GeO_4. But the general conclusion was that this form probably does not exist. However, in 1954, Roy and Roy[4] reported the reproducible synthesis and reversible inversion to olivine of a spinel form of Mg_2GeO_4. This work has been generally missed, since the paper describing it was concerned with the morphology of synthetic serpentines. In 1955, a quantitative equilibrium study of the whole problem was started with the view of determining the pressure–temperature conditions for the inversion of natural olivines into spinel structures. The problem was tackled in stages by determining a series of *t–x* sections of the Mg_2SiO_4–Mg_2GeO_4 system; the study of *t–x* sections with 10 and 20 mol. per cent Fe^{2+} replacing Mg^{2+}, and finally a *p–x* section of the Mg_2GeO_4–Mg_2SiO_4 system at 542° C. up to the experimental limit of 65,000 atm. Many of these results were presented orally at the 1956 annual meeting of the Geological Society of America[5]. While the results of this extensive experimental study will be published later elsewhere, it is considered worth while to summarize here the new data on the spinel–olivine inversion obtained from some four hundred runs in hydrostatic or uniaxial pressure devices.

The work utilized high-pressure water as a catalyst, and under such conditions there is no problem with reproducible synthesis of the spinel phase. The inversion temperature for the Mg_2GeO_4 (spinel) $\rightleftarrows$ Mg_2GeO_4 (olivine) equilibrium (obtained by extrapolation from runs as low as 1,000 lb./sq. in.) is 810° C. at atmospheric pressure. The ΔV of inversion from X-ray data is 3·5 cm.^{3}/mol.; ΔH (calculated from the pressure-dependence slope) is 3,690 cal./mol. The entropy of inversion is thus a reasonable 3·4 E.U. The inversion temperature is raised by 0·025 deg. C./bar for the first 5,500 bars. X-ray intensities and infra-red absorption spectra clearly show that Mg_2GeO_4 is an inverse spinel. It may be of interest to record that the inversion in Mg_2SiO_4 as determined by extrapolation of experimental points up to 60 mol. per cent Mg_2SiO_4 in the *p–x* section is set at 100 ± 15 kilobars at 542° C. Further, the change in lattice spacings of the spinel solid solutions of Mg_2GeO_4·Mg_2SiO_4 shows that the spinel form of Mg_2SiO_4 will have a cell edge of 8·22 A. Therefore, the ΔV of this transition is 2·0 cm.^{3}/mol. The dependence of the Mg_2SiO_4 transition upon pressure is beyond direct experimental study at present, but from a consideration of various sections in the *p–t–x* volume constructed with the data for the system Mg_2GeO_4–Mg_2SiO_4, one would expect that it will be only 0·013 deg. C./bar.

BIOCHEMISTRY

Chlorination of Proteins as a Method of increasing their Opacity in the Electron Microscope

THE basic difficulty in devising a method for selectively increasing the density of protein in a tissue section, in order to increase its contrast under the electron microscope, is to choose some atom or group of atoms unique to the protein, and which may be replaced or substituted by some heavier atom or group. The amide group occurs in all proteins as the peptide link, while it is absent in all other macromolecular cell constituents. N-chlorination(·NH·CO·→ ·NCl·CO·) is a well-known reaction with simple amides, and it therefore seemed that chlorination might offer a simple means of increasing the density of the protein. Although chlorination of other cell constituents (and other structures in the protein) would undoubtedly also occur, it was considered that the background increase in density produced in this way would be small compared with the increase in density of the protein, for theoretically 1 gm. atom of chlorine can react with each 100–150 gm. of protein, depending upon its amino-acid composition. Vandevelde[1] has shown that many proteins, both fibrous and globular, react with chlorine to give materials which contain about 15 per cent chlorine, a content which corresponds to substitution at most of the peptide links. Most of the chlorine is lost from the modified protein by treatment with water, giving hydrochloric acid, which probably arises by hydrolysis of the N—Cl bond followed by oxidation of the protein by the hypochlorous acid which is formed. Exposure to chlorine gas, followed by spraying with iodine and starch solutions, has been used as a delicate test for amino-acid, peptide and protein spots on paper chromatograms[2].

Table 1. CHLORINATION OF VARIOUS PROTEINS BY *tert.* BUTYLHYPOCHLORITE ($((CH_3)_3 \cdot C \cdot OCl)$) IN ANHYDROUS PETROLEUM ETHER

Protein	Gm. protein per gm. atom of chlorine absorbed		
	20 hr.	60 hr.	160 hr.
Native albumin	12,500	4,460	1,057
Alcohol denatured albumin	538	223	132
Fibrin	106	102	100
Keratin	3,570	777	509

We have studied the uptake of chlorine by several dried proteins, suspended in anhydrous solutions of chlorine or *tert.* butylhypochlorite[3] in inert solvents, by estimating the excess active chlorine by iodometry after a given time. The results of a typical experiment are shown in Table 1.

Similar results were obtained with chlorine in dry carbon tetrachloride ; in a number of cases estimation of the chlorine content of the modified protein by the Carius method showed that these figures were essentially correct. Denatured albumin, like the fibrous protein, fibrin, reacted much faster than native albumin, presumably because the disordered peptide chains were more freely accessible to the chlorinating agent. Keratin, in which the structure is additionally stabilized by disulphide cross-links, showed an intermediate reactivity.

In order to test whether a useful increase in contrast under the electron microscope would be observed in protein treated in this way, horse red blood cell erythrocytes were suitable as test objects because they consist largely of protein and are not completely opaque to electrons with accelerating potentials of the order of 75 kV. A bulk preparation of erythrocytes was made by the method of Hillier and Hoffman[4], and after denaturation with alcohol and thorough drying, this material was chlorinated (chlorine in carbon tetrachloride for 24 hr.). The treated erythrocytes contained 11·2 per cent chlorine, and titration of the excess chlorinating agent gave a figure of 206 gm./gm. atom of chlorine absorbed. For electron microscopy, the erythrocytes were deposited directly on an evaporated carbon film mounted on a copper grid, by allowing a small drop of dilute aqueous suspension to evaporate. After immersion in alcohol for several hours, the grids were dried for several days over calcium chloride before they were exposed to dry chlorine gas for 24 hr. Many experiments of this type were made, and under the interference microscope the erythrocytes appeared largely undamaged, provided anhydrous conditions were rigorously maintained. However, under the electron microscope, at a magnification of 10,000–20,000, it was never possible to find a specimen in which the fine structure was not badly disrupted. Frequently a twisted mass of filaments and spirals was observed, and it was consequently impossible to obtain reliable density measurements.

Hydrogen-bonding through the >NH group must necessarily be destroyed by chlorination at the peptide link, and it is this bonding which is thought to be important in maintaining the precise geometry of the folded peptide chains. It is considered that the type of damage observed, together with the rates and extent of chlorine uptake by different types of proteins, is consistent with the view that chlorination at the peptide link occurs with breakdown of hydrogen-bonding between individual amino-acids in the peptide chains, and between peptide chains. If this view is correct, other methods of substitution at the peptide link would also lead to destruction of the protein ultrastructure.

We are indebted to Prof. J. T. Randall and Dr. S. Fritton-Jackson of the Wheatstone Physics Laboratory, King's College, who carried out the electron microscopy. One of us (M. M. C.) wishes to thank the Nuffield Foundation for a research fellowship, during the tenure of which this work was carried out.

Glucose-*cyclo*-Acetoacetate as a Precursor of Ascorbic Acid in Germinating Green Gram

THAT glucose-*cyclo*-acetoacetate acts as a precursor of ascorbic acid in germinating green gram or mung beans (*Phaseolus radiatus*) has been shown by Nath and his associates[1–3] and confirmed by the use of labelled glucose-*cyclo*-acetoacetate by Thangamani and Sarma[4]. Neither the titrometric indophenol dye method of Bessey and King[5] nor the colorimetric method of Roe and Kuether[6] is specific for L-ascorbic acid. We have therefore used paper chromatography to identify the additional reducing substance formed from glucose-*cyclo*-acetoacetate during the process of germination which decolorizes the indophenol dye, and find it to be L-ascorbic acid.

If glucose-*cyclo*-acetoacetate were a true precursor of ascorbic acid in such a process, the chromatograph would be expected to show greater biosynthesis of ascorbic acid (as indicated by a specific R_F value) on the addition of glucose-*cyclo*-acetoacetate in the germinating medium. The amount of ascorbic acid formed would also be expected to be directly proportional to the amount of glucose-*cyclo*-acetoacetate added.

We adopted the technique of circular paper chromatography used by Nath and Bhattathiry[7] to identify another dienol compound (1 : 2 dienol glucose) in normal blood, and silver nitrate–ammonia was used for staining the chromatogram, as used by Partridge[8] for ascorbic acid.

Chromatograms with a standard ascorbic acid solution and deproteinized extracts of the same weight of seeds germinated for 72 hr. in (*a*) water and (*b*) aqueous solutions of glucose-*cyclo*-acetoacetate, using either 50 mgm./100 seeds or 100 mgm./100 seeds, were obtained. Whatman filter paper No. 1 of 28 cm. diameter fitted with a wick at the central hole was employed, in a Petri dish placed in a closed chamber with a solvent mixture consisting of butanol/acetic acid/water (40 : 10 : 50), the top layer being used. The paper was allowed to dry in air and the staining was done by spraying with a cold solution of silver nitrate–ammonia.

It will be evident from the bands in the chromatogram (Fig. 1) that all of them have the same R_F value, namely, 0·52, which was found to be specific for ascorbic acid by Nath and Bhattathiry[7]. The intensity of the colour of the (G_2) bands with 100 mgm. glucose-*cyclo*-acetoacetate/100 seeds is much greater than that of the (G_1) band with

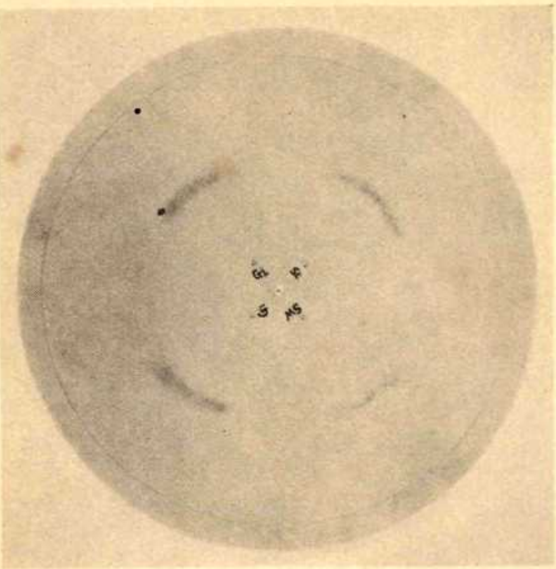

Fig. 1. Circular paper chromatogram showing: *St*, standard ascorbic acid solution; *SW*, aqueous extracts of seeds germinated in water alone; G_1 and G_2, aqueous extracts of seeds germinated with glucose-*cyclo*-acetoacetate (50 mgm. and 100 mgm./100 seeds respectively)

50 mgm. glucose-*cyclo*-acetoacetate/100 seeds, which is again much greater than that (*SW*) with seeds germinated in water only. This confirms that the reducing substance formed from glucose-*cyclo*-acetoacetate during the process of germination of mung beans is ascorbic acid and its biosynthesis varies directly with the amount of glucose-*cyclo*-acetoacetate added.

We wish to thank the Council of Scientific and Industrial Research for a research grant, and Mr. B. I. Uppin for technical assistance.

PHYSIOLOGY

Antagonism of Choline and Inositol

SIMULTANEOUS administration of choline and inositol to rats prevents the formation of fatty liver to a greater extent than if either substance were given alone[1]. There have also been several isolated reports which suggest to us the existence of an antagonism between choline and inositol. Suppression by choline of the growth of yeast requiring inositol has been reported by Taylor and McKibbin[2]. The addition of choline depressed growth under conditions in which growth was limited by the concentration of inositol in the incubation medium. Also, in studies of renal necrosis found in developing rats fed a diet deficient in choline, Handler[3] observed that the addition of inositol to that diet greatly aggravated the renal necrosis, while it reduced the degree of liver fat in the same animals.

In a study of perosis (slipped tendon) of the developing turkey fed a diet deficient in choline, Jukes[4] observed that dietary inositol cannot relieve the perosis and may even accelerate its appearance. The experiments reported here establish that the addition of inositol to the diet of chicks deficient in choline causes a marked aggravation of perosis, both in rate of appearance and in degree, and that the degree of perosis is intensified by increasing the amount of added dietary inositol (Table 1).

Table 1. EFFECT OF INOSITOL UPON PEROSIS AND GROWTH OF CHOLINE-DEFICIENT CHICKS

Diet	Average perosis score per chick		Average body-weight ± *S.E.* (gm.)	
Added inositol (per cent)	After 2 weeks	After 4 weeks	After 2 weeks	After 4 weeks
0	0·25	2·75	110 ± 3	263 ± 10
0·2	0·88	3·68	116 ± 4	244 ± 19
1·0	1·8	4·5	108 ± 7	224 ± 27

Eight New Hampshire chicks, one day old, were placed on each diet (Table 1) *ad libitum* for four weeks. The basal diet consisted of 'Drackett *C*1' soy protein, 300 gm.; L-cystine, 3 gm.; corn oil, 40 gm.; salts *A*, 60 gm.; crude glucose, 597 gm.; thiamine hydrochloride, 8 mgm.; riboflavin, 8 mgm.; calcium pantothenate, 20 mgm.; nicotinic acid, 100 mgm.; pyridoxine hydrochloride, 8 mgm.; D-biotin, 0·3 mgm.; pteroyl glutamic acid, 3 mgm.; vitamin B_{12}, 0·1 mgm.; vitamin A acetate, 6 mgm.; α-tocopherol, 25 mgm.; α-tocopherol acetate, 25 mgm.; vitamin D_3, 0·02 mgm.; 2-methyl-1,4-naphthoquinone, 1 mgm. The degree of perosis was graded from zero to three by the gross appearance of each leg: maximum severity, designated by a score of 3 for each leg, representing complete loss of the use of the leg.

While the mechanism of the lipotropic action of inositol and choline *in vivo* is still unknown, it is of interest that recent experiments on the biosynthesis of lipids indicate the presence of common intermediates which participate in the formation of inositol- and choline-phosphatides as well as triglycerides[5,6]:

$$\begin{tikzcd}
\text{L-}\alpha\text{-glycerophosphate} \arrow[d, "2\,RCO\text{-CoA}"] & \\
\text{L-}\alpha\text{-phosphatidic acid} \arrow[r, "\text{cytidine nucleotide}", "\text{inositol}"'] \arrow[d] & \text{inositol-phosphatide} \\
\text{D-}\alpha,\beta\text{-diglyceride} \arrow[r, "CDP\text{-choline}"] \arrow[d, "RCO\text{-CoA}"] & \text{lecithin} \\
\text{triglyceride} &
\end{tikzcd}$$

This scheme suggests that either choline or inositol might exert a lipotropic effect by stimulating formation of the corresponding phosphatide, in which form fatty acids are perhaps more soluble or are otherwise made more accessible to further metabolism than they are in the form of triglycerides.

On the other hand, during periods of rapid synthesis of cells, such as the growth of a young animal, it is likely that specific phosphatides are required for the formation of cellular and subcellular constituents and that for this purpose inositol and choline are not interchangeable.

Thus there is evidence suggesting synergism between inositol and choline from experiments related to lipotropic action, and there is also evidence of antagonism in experiments related to growth. This paradox may be explained by present knowledge at the enzyme-level. The synergistic lipotropic action may be related to a shunt of precursors away from triglyceride formation by either inositol or choline, while the antagonism may be related to depression of the formation of a particular structural phosphatide by the precursor of another, for example, lecithin, by inositol under conditions in which low levels of choline are present.

Sodium, Potassium, Calcium and Chloride Ion Contents and Protein Fractions in the Fluids of Chick Embryos

Among substances present in the amniotic fluid, the protein fractions and mineral components preserving osmotic equilibrium between the amnion and the growing embryo itself are especially significant for the development of the embryo.

In the present investigation, the amniotic fluid from incubated hen's eggs was used and for comparison the allantoic fluid and the rest protein of fertile eggs between the tenth and seventeenth days of incubation. For this purpose, a culture of embryos was grown at the Institute of Medical Microbiology of the Medical Academy at Poznań. The amniotic and allantoic fluids were extracted with an aseptic needle and syringe after breaking the egg shell, and were transferred to corked aseptic tubes. Protein from incubated eggs was placed in weighed test-tubes containing a physiological salt solution or buffer solution necessary for electrophoretical investigations. The fluids and protein were kept in a refrigerator until used in experiments.

The level of sodium, potassium and calcium ions in the amniotic and allantoic fluids was determined with a flame photometer (Zeiss, Jena), and their contents expressed in milliequivalents. The chloride ion content was determined by Volhard's method and also expressed in milliequivalents. The total protein content was examined by the biuret method[1], using a Coleman spectrophotometer. The protein fractions of both fluids and the rest protein were separated by free electrophoresis ('Fokal' *F* apparatus, constructed according to Arne Tiselius by Strübin, Basle). For obtaining protein diagrams the following buffer solution was used: veronal sodium salt, 5·88 gm.; sodium acetate ($CH_3COONa.3H_2O$), 3·88 gm.; potassium oxalate ($(COOK)_2.2H_2O$). 1·38 gm.; hydrochloric acid 0·1 *N* (HCl), 20·00 ml.; distilled water to 1 litre. Such a solution has *p*H 8·9, and ionic strength μ 0·1. Before electrophoresis, the amniotic and allantoic fluids of low protein contents were condensed *in vacuo* over phosphorus pentoxide to a concentration of 1 per cent protein.

Table 1. Mean Ion Contents (in m.equiv.) of the Amniotic and Allantoic Fluids of Normally Developing Chick Embryo

Ions	Days of life							
	10	11	12	13	14	15	16	17
	Amniotic fluid							
Na^+	127	134	130	132	112	107	119	118
K^+	4·1	4·5	4·7	7·0	21·8	23·8	19·2	18·0
Ca^{2+}	—	1·6	2·1	3·5	4·7	3·6	—	3·2
Cl^-	—	131	141	144	108	—	—	—
	Allantoic fluid							
Na^+	—	115	110	105	84	82	—	—
K^+	—	12·0	13·0	20·0	25·0	26·0	—	—
Ca^{2+}	—	3·5	2·0	2·4	1·5	2·0	—	—
Cl^-	—	68	90	84	72	—	—	—

The results of measurements of the concentration of mineral components in both fluids of the growing chick embryo, undergoing normal development between the tenth and seventeenth day of its life, are shown in Table 1.

In physiological conditions, the concentrations of sodium and chloride ions in the amniotic fluid drop as the embryo develops, that is, as incubation proceeds; starting from the thirteenth or fourteenth day of the life of the embryo, the level of potassium ion rises to 4–5 times its value in the earlier days. The allantoic fluid was found to undergo analogous changes in ion content; however, the potassium ion has originally a higher concentration here than in the amniotic fluid. The sodium and calcium ions have lower concentrations in the allantoic fluid than in the amniotic fluid.

The present results differ from those of Kamei[2], obtained in 1927, especially with regard to sodium, potassium and calcium ion determinations in both fluids. The fact that Kamei obtained higher values for these ions is probably due to his use of gravimetric methods: sodium and potassium were weighed as chloride, potassium was estimated separately as potassium chloroplatinate (K_2PtCl_6) and the sodium ion level determined by subtraction. Kamei's results for chloride generally coincide with the present results, though they are somewhat higher. It is also possible that the discrepancy arises from some differences in the races of hens used for investigation.

Daily control of the levels of ions made it possible to detect differences in the level of potassium ions between the twelfth, thirteenth and fourteenth days of the embryo in both fluids. This was not noticed by Kamei, whose measurements date from the ninth and fourteenth day.

Simultaneously with the rise in content of potassium ions in the amniotic fluid, the protein content undergoes a marked change on the thirteenth or fourteenth day of the life of the embryo. In fact, determinations of the total protein showed the amniotic fluid to be poor in protein during the eleventh to thirteenth days of embryonic development, when the protein concentration amounts to no more than 0·5 gm. per 100 ml. of the fluid. On the other hand, the amniotic fluid of an embryo more than 14 days old is highly proteinous, containing 9–10 gm. of protein per 100 ml. of the fluid.

The amniotic fluid of low protein content, on being concentrated *in vacuo*, showed three fractions on the electrophoretic diagram. That with the greatest velocity contains about 98 per cent of the total amount of protein, the two remaining fractions containing but 1 per cent each (Fig. 1*a*). Allantoic fluid of low protein content exhibited a similar electrophoretic diagram.

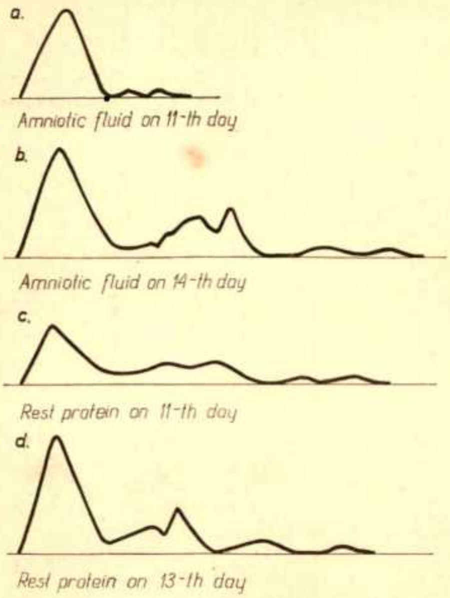

Fig. 1. Electrophoretic diagrams obtained in free electrophoresis in 'Fokal' *F* apparatus

The highly proteinous amniotic fluid of the fourteenth day contains five electrophoretically distinct fractions (Fig. 1*b*). The largest, amounting to 62 per cent of the total protein, presents a broad base in the diagram, which proves it to be inhomogeneous. The second, third and fourth fractions amount respectively to about 17, 10 and 8 per cent of the total protein. The latter fraction, in the buffer solution used, moves towards the cathode, and amounts to about 3 per cent of the total protein. The rest protein of incubated eggs on the eleventh and thirteenth days exhibited similar electrophoretic diagrams (Fig. 1*c* and *d*); the diagram on the eleventh day shows weakly developed gradients.

The similarity of the diagrams obtained with highly proteinous amniotic fluid and that of the rest protein of the incubated egg on its thirteenth day is noteworthy (Fig. 1*b* and *d*). It had already been observed by M. E. Marshall[3] in the amniotic fluid of the incubated egg and the protein from newly laid egg.

The biochemical changes in the composition of the amniotic fluid and in the amount of total protein, between the twelfth and fourteenth days of the life of the embryo, observed as a stepwise variation in the potassium ion and total protein contents and as variations in the electrophoretically separated protein fractions, are probably caused by the serum–amniotic junction.

I am indebted to Prof. Jan Adamski (Institute of Medical Microbiology, Medical Academy, Poznań) for the material received for investigation, and to Prof. Jan Roguski (IInd Clinic of Internal Medicine, Medical Academy, Poznań) for permission to carry out the electrophoretic analysis in his laboratory.

Demonstration of Small Components in Red Cell Hæmolysates by Starch-gel Electrophoresis

STARCH-GEL electrophoresis[1] has been used successfully for the investigation of human and animal sera; it is superior to other methods because it affords greater resolution and ability to demonstrate small components. The same method has also been applied to the study of human hæmoglobin, although the results reported so far[2-4] have not provided information different from that obtainable by other electrophoretic techniques.

We have used this supporting medium with phosphate buffer (pH 6·5, $\Gamma/2$ 0·033) in the electrode vessels and for the preparation of the gels (12 gm./100 ml. of hydrolysed starch, Connaught Laboratories, Toronto). The hæmoglobin solution (10–15 gm./100 ml.) is introduced into suitable slits either on a double piece of filter paper (Whatman 3*MM*) or as a paste moulded with unboiled starch. Direct current at 280 V. and 26 m.amp. is applied for 6–8 hr. to two plastic trays, each measuring 250 mm. × 60 mm. × 6·5 mm. After completion of the run one of the cut surfaces is stained for protein[1] and the other is treated with a benzidine reagent[2]; the concentration of hydrogen peroxide in the latter is preferably kept low (1–3 per mille) in order to avoid distortion of the gel by catalase activity.

A coloured zone at the position of hæmoglobin *A* is still demonstrable with benzidine when the hæmoglobin solution applied has been diluted to 1 part in 2,000, and with amidoschwartz at a dilution of 1 part in 500. The electrophoretic pattern appears similar whether the hæmolysate is freed of stromal material by extraction with toluene, by precipitation with phosphate buffer (0·3 *M*, pH 6·8) or by high-speed centrifugation. For the identification of some zones a two-dimensional technique[5] has been applied (paper electrophoresis at pH 8·6 or 6·7, followed by starch-gel electrophoresis at pH 6·5 of segments cut longitudinally to the direction of migration).

Under the above conditions the normal hæmoglobins A_2, *F* and *A* move in that order a short distance toward the cathode, hæmoglobin *F* not separating from *A*; all other fractions migrate away from the point of insertion to the anode. By protein stain the following zones can regularly be observed (Fig. 1):

Zone 1, placed immediately after the slit of insertion, benzidine negative, is always present in adults, but is absent or only barely visible in cord blood; it corresponds to a protein which on paper, starch-

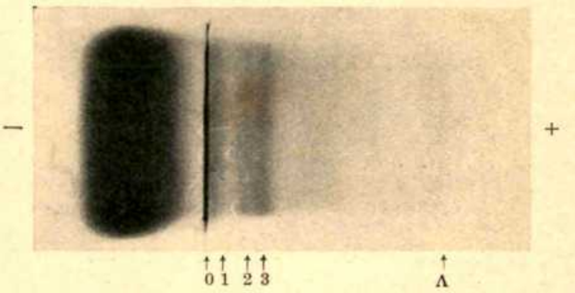

Fig. 1. Starch-gel electrophoresis of red cell hæmolysate from adult blood, 6 hr., amidoschwarz stain. 0, application slit. Numbers and letters correspond to zones described in text. The weaker fractions ahead of band Λ are not reproduced on the photograph

block and starch-gel electrophoresis at pH 8·6 migrates slightly more slowly than A_2.

Zone 2 is a narrow band, which probably corresponds to catalase, because oxygen is liberated only in this area ; at low concentrations of hydrogen peroxide a thin benzidine-positive line appears in this region.

Zone 3, closely following 2, is very prominent and occurs in both adult and cord blood. It is followed by a number (usually 3–4) of weak and less sharply delineated bands, which have not been identified.

The zone designated Λ occupies the same position as serum albumin ; in the presence of traces of serum in the hæmolysate this band stains more intensely and, at times, may also be demonstrated by the benzidine reagent as a weak line. This observation suggests binding of hæmoglobin or its derivatives by albumin. A zone with similar properties is also demonstrable on starch gels used with borate buffer, pH 8·4 ; in both buffers it is of definitely higher anodic mobility than hæmoglobin H (Fig. 2). The characteristics of this zone are reminiscent of the small fraction V observed by Huisman and Martis in many samples by chromatography on carboxymethylcellulose[6].

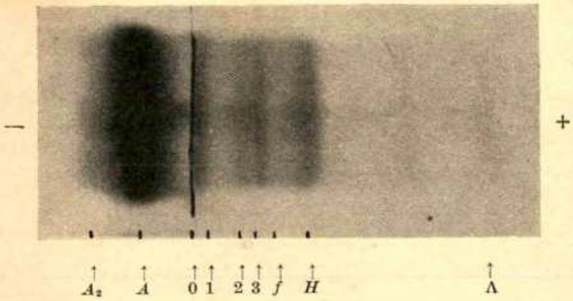

Fig. 2. Electrophoresis of hæmoglobin from an adult with hæmoglobin H, 8 hr., amidoschwarz stain. Symbols as for Fig. 1; f indicates relative position of 'fast' fœtal hæmoglobin

Three further very weak zones, not identified, precede band Λ towards the anode.

By means of the benzidine reagent we were able to demonstrate in all samples of cord blood a well-defined zone with peroxidase activity, situated only slightly ahead of zone 3 (Fig. 3) ; it is estimated to amount to 0·5–1 per cent of the total hæmoglobin. The position of this band, as well as evidence obtained by the two-dimensional technique, strongly suggest that it corresponds to a 'fast' fœtal hæmoglobin, increased levels of which have been observed in several cases by paper electrophoresis (ref. 7 and Vella, F., and Lie-Injo Luan Eng, personal communications and unpublished results). This zone has not been found in adults ; however, minimal amounts were detected in four adults with hereditary anæmias and increased levels of hæmoglobin F (12–20 per cent). Conversely, this same fraction was definitely present in four cases presenting hæmoglobin H—which is of higher anodic mobility—and a minimal increase of the alkali-resistant pigment.

For the separation of certain hæmoglobin variants and of components which at alkaline pH move slower than A (such as hæmoglobin A_2, the protein of zone 1 and a further red cell protein), borate buffer at pH 8·4[1] or *tris* buffer[8] are preferable to the phosphate used here ; hæmoglobin H, the 'fast' fœtal fraction and zone Λ can also be demonstrated in borate buffer. However, the delineation of components with a higher anodic mobility than hæmoglobin A is generally superior in phosphate. Furthermore, under the above conditions, the mobility of the zones is not affected by their relative concentration.

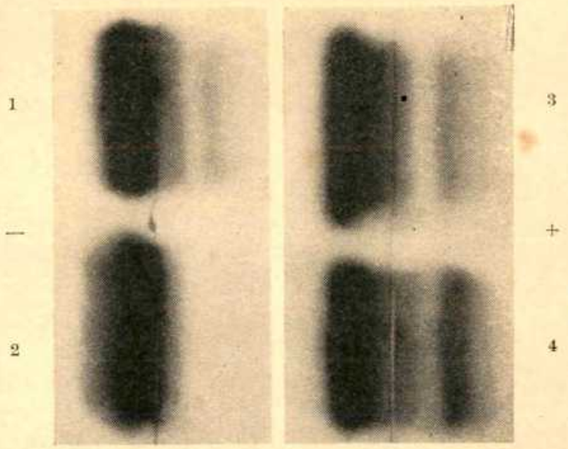

Fig. 3. Comparison of (1) normal cord blood hæmoglobin with (2) normal adult hæmoglobin, and (3) hæmoglobin from cord blood of a 6 months premature infant with (4) cord blood presenting a very high percentage of the fast fœtal fraction. Starch gel electrophoresis for 6 hr., treated with benzidine reagent

It is believed that this method, although not yet suitable for accurate, quantitative use, has the advantage of clearly demonstrating minor components of red cell hæmolysates, not well shown by other electrophoretic procedures. Work on the nature of the zones observed and their alterations in various conditions is in progress.

Distribution of Alkaline Phosphatase in the Arteries of Several Species

A CHANCE observation in our laboratory led us to study the activity of the alkaline non-specific monoesterase in the arterial wall. The distribution of this enzyme within the arteries has received but scant attention and contradictory reports appear in the literature. Kay[1] states that none is found when chemical methods are used, whereas Gomori[2], using a histochemical technique, reports that the enzyme is found in the adventitia of medium-sized arteries. In the human being, no activity has been found[3] chemically in the aorta at an alkaline pH, or only traces found in this vessel and in other arteries[4] ; on the other hand, the enzyme has been demonstrated histochemically in early atheromatous plaques[5] as well as chemically in peripheral arteries[6].

The present observations show that the activity of alkaline phosphatase is not uniform and that there are differences between arterial territories as well as between species; it seems possible that conflicting reports may be due to this fact. Furthermore, an interesting and unexplained fact has been disclosed, namely, an apparent inverse relationship between the enzyme activity and the ability of several species to develop atherosclerosis induced by cholesterol.

Rabbits, chickens and rats were anæsthetized with sodium pentobarbital, blood collected and the arterial system perfused with saline in order to avoid contamination with blood. The aorta and the cerebral vessels (free from the choroid plexus) were removed, blotted with filter paper and weighed; they were then frozen and cut into 10μ sections with a microtome, homogenized and the enzyme activity in approximately 20 mgm. of tissue determined by the method described by Kaplan and Narahara for blood serum[7]. Incubation was carried out at 37° C. for 30 min. with disodium phenylphosphate as substrate, and with sodium borate buffer at *p*H 9·4. The enzyme was also determined in citrated plasma.

The results, expressed in μmoles of phenol liberated under the stated conditions, are shown in Table 1. It can be seen that the alkaline phosphatase activity is similar in the plasma of rabbits (50·1 ± 7·17 μmoles/ml., mean ± standard error) and rats (60·9 ± 4·40) whereas it is much higher in chickens (303·0 ± 24·7). In the aorta, however, the activity was very low in rabbits (0·06 ± 0·006) and in chickens (0·14 ± 0·018), while it was 0·48 ± 0·028 in the rat. In the cerebral vessels it was strikingly higher and also different in the three species (0·21, 2·74 and 1·10, in the rabbit, rat and chicken respectively). It must thus be concluded that the alkaline phosphatase content of the vessels is not the same in different species, that plasma values bear no relationship to the arterial activity and that the cerebral vessels have a much greater enzymatic concentration than the aorta.

Table 1. ALKALINE PHOSPHATASE ACTIVITY IN SEVERAL SPECIES (IN μMOLES OF PHENOL LIBERATED UNDER STANDARDIZED CONDITIONS; MEAN ± STANDARD ERROR)

Animal	Plasma (per ml.)	Aorta (per mgm. of wet tissue)	Cerebral vessels (per mgm. of wet tissue)
Rabbit	(18) 50·1 ± 7·17	(14) 0·06 ± 0·006	0·21*
Rat	(12) 60·9 ± 4·40	(16) 0·48 ± 0·028	2·74†
Chicken	(10) 303·0 ± 24·7	(10) 0·14 ± 0·018	1·10†

All determinations were carried out in duplicate; figures in parentheses, number of animals.

* Six determinations on pools of three animals.

† Two determinations on pools of six animals.

Although very little is known about the chemical reactions which might be catalysed by alkaline phosphatase in the arterial wall, the changes that the enzyme might undergo in different circumstances seem to be worthy of study. Finally, it is also of interest in connexion with the problem of atherosclerosis, that in rabbits and chickens atherosclerosis is easily induced by cholesterol[8], and they have very little alkaline phosphatase in the aorta, whereas rats show a high enzymatic activity and very rarely develop the disease[9]; furthermore, cerebral lesions are not seen even in atheromatous rabbits which have been fed cholesterol[10] and, as was shown, the cerebral vessels possess a high alkaline phosphatase activity. Further work on these apparent relationships is clearly needed and is being undertaken in our laboratory. Results will be published in more detail elsewhere.

We are grateful to Prof. Eduardo Braun Menendez for helpful suggestions and criticisms.

A Germination Inhibitor and Root-Growth Retarder in Chou Moellier (*Brassica oleracea* var.)

INVESTIGATIONS are being undertaken at this Station into local problems associated with the establishment of new pastures. Such pastures are commonly sown in the autumn following a summer crop of chou moellier (marrow stem kale), *Brassica oleracea* var. A frequent outcome of such sowings is that the grass components of the seeds mixture germinate and grow apparently normally, while the legume component may or may not germinate. If the seeds of the legume component (chiefly white clover) do germinate, and seedlings emerge, they frequently die off in four to six weeks.

In the course of *in vitro* studies undertaken to throw light on this problem of clover seedling mortality the presence of a germination inhibitor in chou moellier has been demonstrated. A technique has been used in which ten white clover (*Trifolium repens*) seeds are sown on a filter paper in a Petri dish, while on a second filter paper slightly overlapping the first are placed sections of chou roots, stems or leaves, or finely minced parts of these organs. The seeds are then provided with sufficient moisture for germination by applying water to the chou plant material and allowing it to pass to the seeds across the bridge formed by the overlapping filter papers.

The germination in eight days of white clover seeds has been reduced from 87 per cent in the controls to 10 per cent where minced chou roots were present on the adjacent filter paper, with lesser reductions in germination where minced stems and leaves and unminced sections of the roots were present.

The inhibitory effect appears to be irreversible, since ungerminated seeds removed after eight days from the presence of chou roots, leaves and stems to clean filter paper in Petri dishes uncontaminated by chou plant material and watered with distilled water failed to germinate after a further ten days.

In the few cases where clover seeds were able to germinate in the presence of chou moellier roots, the seedling radicles became blackened at the tip, root hairs were very sparse by comparison with the control seedlings, and within three weeks the seedlings adjacent to the chou roots had all died.

Evaluation of the part played by the inhibitor in the field mortality of clover seedlings awaits the result of field trials now in progress.

The effect of the inhibitor has also been studied in relation to germination and subsequent growth of perennial ryegrass (*Lolium perenne*) and New Zealand short rotation ryegrass (*L. perenne* × *L. multiflorum*). With neither species did the presence of chou roots, leaves or stems reduce germination percentage. However, using the technique outlined above for clovers, the presence of sections of chou roots on the adjacent filter paper had a most striking effect on the total root length per rye-grass seedling. The mean root lengths in millimetres, for 30 seedlings in each case, are given in Table 1.

Table 1

	Controls	With chou roots
Perennial rye-grass	24 mm.	5 mm.
Short rotation rye-grass	26 mm.	1 mm.

Later observations suggest that parts of the swede turnip plant and of the common weed spurrey (*Spergula arvensis*) may have similar effects.

Enzymic Nature of the Serum Globulin Permeability Factor

The globulin permeability factors obtainable from the serum of man[1], guinea pig[2,3], rat[4] and rabbit[4] appear to be proteases because they are highly active on vascular endothelium—on a molar basis, they are 60–2,000 times as active as histamine, itself a potent permeability factor[5]; and because they are readily inhibited by prior treatment *in vitro* with the trypsin inhibitors from soya bean, lima bean and bovine pancreas. The action of these inhibitors, however, is apparently very rapid, a mixture of factor and inhibitor only 1 min. old being inactive when injected into the skin of animals with circulating pontamine blue[4,7]. Consequently, it is impossible to distinguish inactivation of a protease permeability factor *in vitro* from inactivation of a protease newly activated *in vivo*. Moreover, even the best preparations of permeability factors also contain known serum proteases, and so far no enzyme substrate has been found which is hydrolysed by serum fractions in strict proportion to their content of permeability factor.

The enzymic nature of the factors was more firmly established when one of us (E. L. B.[6]) demonstrated that guinea pig permeability globulin was irreversibly inactivated by prior treatment *in vitro* with di*iso*propyl phosphofluoridate and subsequent dialysis to remove excess di*iso*propyl phosphofluoridate. Thus, treatment with $4\cdot4 \times 10^{-4}$ *M* di*iso*propyl phosphofluoridate for 2 hr. at 37° completely inactivates 54 'effective blueing doses' (EBD)[7]. Since the inactivation *in vitro* (Table 1) is slow and progressive, the drug cannot be suppressing a protease activated *in vivo*. Furthermore, the minimally effective concentration of di*iso*propyl phosphofluoridate for inactivation at 37° C. for 1 hr. is of the order of 10^{-5} *M*, a concentration like that inactivating trypsin, in contrast to concentrations of 10^{-8}–10^{-9} *M* effective on enzymes with a more restricted esterase activity[8], for example, choline esterase.

Table 1. PROGRESSIVE INHIBITION OF PERMEABILITY-INCREASING POTENCY OF GUINEA PIG FACTOR BY PRIOR TREATMENT *in vitro* WITH DI*iso*PROPYL PHOSPHOFLUORIDATE (DFP)

Amt. factor (EBD)	Concn. DFP (*M*)	Percentage inhibition after treatment with DFP for			
		½ hr.	1 hr.	2 hr.	6 hr.
2	$3\cdot3 \times 10^{-6}$	*nt*	*nt*	33	39
2	1×10^{-5}	39	59	75	75
6	1×10^{-5}	*nt*	48	89	92
6	$3\cdot3 \times 10^{-5}$	50	63	82	98
18	1×10^{-4}	39	83	96	100

EBD, Effective blueing dose; *nt*, not tested.

Nevertheless, the factors in guinea pig and rat serum, if they are enzymes, appear to attack ester linkages. Thus 0·01 *M* of both *p*-toluene sulphonyl L-arginine methyl ester and of benzoyl L-arginine methyl ester prevent inactivation of the guinea pig factor by $2\cdot5 \times 10^{-4}$ *M* di*iso*propyl phosphofluoridate. The ethyl esters of L-leucine, L-lysine, L-phenylalanine, DL-serine, L-tyrosine and acetyl L-tyrosine were ineffective in concentrations of 0·01 *M*. Rat factor is also protected by *p*-toluene sulphonyl L-arginine methyl ester, 0·003 *M* successfully competing with 10^{-3} *M* di*iso*propyl phosphofluoridate. These facts are compatible with the serum factors being proteolytic enzymes with an active site similar to that of trypsin. They are distinguished from trypsin by their insusceptibility to the trypsin inhibitor in ovomucoid[9]. The direct competitive inhibition of the factor by these synthetic amino-acid esters cannot be satisfactorily tested *in vivo* because they are themselves fairly potent permeability factors.

When partially purified preparations of guinea pig factor were fractionated on an N,N-diethylaminoethyl–cellulose column the permeability factor activity was associated with a soya bean inhibitable esterase with a *p*H optimum around 9·0. Treatment of cell-free guinea pig serum with glass particles, which activates the permeability factor[10], also activates a soya bean inhibitable esterase with a *p*H optimum around 9.

Under standard conditions, a fixed dose of di*iso*propyl phosphofluoridate has a remarkably similar effect on the permeability factors from guinea pig, rat and rabbit whether they are tested in the corresponding homologous animal or in either of the two heterologous animals. Prior treatment *in vitro* with 10^{-4} *M* di*iso*propyl phosphofluoridate for 60 min. at 37° C. decreases the permeability-increasing potency in all cases by a factor of about 3, the extreme values being 1·8 and 4·4. It is of interest that the esterase inhibitors[8] diethyl *p*-nitrophenyl phosphate (*E* 600), tetraethyl pyrophosphate and *bis*-mono*iso*propyl aminofluorophosphine oxide, in concentrations up to 3×10^{-4} *M*, do not inactivate the factors, though tetraethyl pyrophosphate has a slight effect at 3×10^{-3} *M*. Systemic tri-O-cresyl phosphate is converted in the liver into an inhibitor of serum and liver aliesterases[11]; when given 4 and 24 hr. previously in the rat, it did not substantially inhibit the permeability effect of histamine, 5-hydroxytryptamine, the histamine-liberating compound 48/80 or rat-serum factor.

The use of di*iso*propyl phosphofluoridate has enabled us to establish more firmly the hypothesis that the globulin permeability factors are proteases. The drug is also useful for distinguishing the permeability effects of the globulin from those of other endogenous factors. Di*iso*propyl phosphofluoridate has no *in vitro* effect on histamine, tested in all three species of animal, or on compound 48/80 and 5-hydroxytryptamine, tested in the rat. But its use as an *in vivo* reagent for identifying effects due to the globulin factors is limited by its toxicity in concentrations that might be expected to inactivate proteases. Thus, 0·1 ml. of 10^{-4} *M* di*iso*propyl phosphofluoridate given intracutaneously is sufficient to induce local fibrillation in the muscles of the skin. Given systemically, di*iso*propyl phosphofluoridate is likely to be even less useful for this purpose, because in non-toxic doses it will effect mainly the numerous esterases of the body susceptible to concentrations of the order of 10^{-8}–10^{-9} *M*.

In contradistinction to the observations of Spector and Willoughby[12] in the rat, in our hands only obviously toxic doses of systemic di*iso*propyl phosphofluoridate decreased the action of globulin permeability factors injected intracutaneously in both rats and guinea pigs. In any event, the action of the globulin factors is not exclusively affected, since the permeability effects of histamine, compound 48/80 and 5-hydroxytryptamine in rats and guinea pigs are depressed to the same extent.

Equilibration of Labelled Magnesium between Sheep Plasma and Red Cells

The following work was undertaken to determine the rate of transfer of magnesium across the sheep erythrocyte membrane held in a stable *in vitro* system. It is considered that such information should be of value in the elucidation of the etiology of hypomagnesæmia.

Samples of heparinized sheep blood, to which a known percentage of isotonic glucose containing carrier-free magnesium-28 had been added, were incubated for different periods at 40° C. During this incubation frequent aeration with a water-saturated gaseous mixture of 5 per cent carbon dioxide and 95 per cent oxygen was carried out. A layer of paraffin above the blood prevented the interchange of gases between the blood and its environment except during aeration. After each relevant period the particular sample was centrifuged under paraffin, *p*H measured and the plasma and erythrocytes separated. The magnesium-28 was counted in each sample and its total magnesium estimated chemically by way of ammonium vanadate (Rook, J. A. F., private communication).

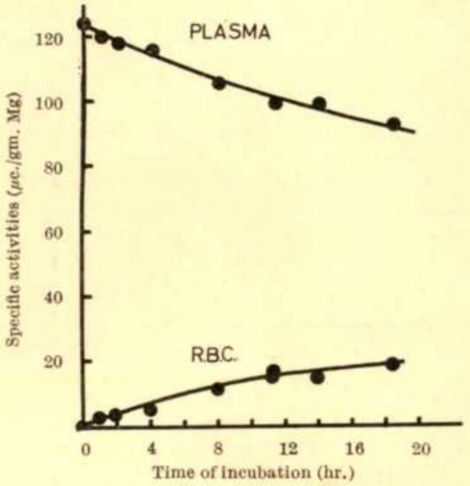

Fig. 1. Magnesium-28 exchange between plasma and red cells of sheep blood

The changes with time of the specific activities of the plasma and erythrocyte magnesium were determined (Fig. 1). The rate of transfer of magnesium between the extracellular and intracellular compartments was calculated by the method used for potassium exchange[1]. It amounted to 3·4 per cent of the plasma magnesium content per hour.

In order to investigate any effect exerted by *p*H on this magnesium transport, the above experiment was repeated at different blood *p*H's. The results showed no significant effect of *p*H on the rate of transport of magnesium between plasma and erythrocytes *in vitro* over the *p*H range studied (7·26–8·07).

The above work, in detail, along with its extension to *in vivo* experiments with sheep, will be published shortly elsewhere.

Detection of Carriers in Hereditary Galactosæmia

ATTEMPTS are being made[1] to detect the heterozygous state for galactosæmia by means of the uridine diphosphoglucose consumption test on erythrocytes —a test devised by us for the detection of galactosæmia[2]. This test was designed so as to give a maximum of difference between normal persons and persons having congenital galactosæmia, in which no galactose-1-phosphate uridyl transferase is discernible in erythrocytes[3,4]. In order to magnify this difference and hence provide an unambiguous proof for the clinician[2,3] this reaction mixture is over-incubated. With near-normal activities, the reaction is brought close to the equilibrium point (cf. refs. 2, 4, 5), and the rates measured are obviously not maximum rates. Experiments in which aliquots for uridine diphosphoglucose determination were taken at 5, 10 and 20 min. incubation time designed to give a quantitative expression of maximum rates have also been carried out[5]. In this work we used the consumption as well as the combined epimerase test[2,3], and yet, only in about two-thirds of the specimens did we succeed in obtaining linearity between incubation time and conversion. Accordingly, we believe it even less likely that the unmodified clinical consumption test (in which only one aliquot at 30 min. incubation is drawn) should be able to detect heterozygous carriers. Therefore, as stated previously[2,6], we do not recommend the consumption test for the latter purpose.

This is not to deny the high degree of reliability of the consumption test and especially our combined test[2,3] for detecting homozygous individuals afflicted with galactosæmia. Not only has the test proved to be reliable and specific, but it also circumvents the loading of afflicted infants with galactose. Moreover, as suggested by Dr. H. N. Kirkman[7], a slight modification of the test may prove useful in spotting galactose-1-phosphate in blood and hence turn attention toward possible faulty diets in case of galactosæmia[7].

We have pointed out on earlier occasions[2,6] that in order to develop reliable techniques for detecting heterozygous carriers in galactosæmia it is necessary to develop methods in which it is possible to obtain accurate and abundant results under conditions in which one can expect maximum rates for galactose-1-phosphate uridyl transferase. Such methods, which were developed more than a year ago by Dr. Kirkman[8], permit the recording of 20–25 points during the period in which the reaction is proceeding at maximum rate. The first results, which were reported some time ago[9], showed that the parents of galactosæmic children frequently manifest partial defects in the above-mentioned enzyme. In a more detailed publication[8] Kirkman evaluates the method and the results. It seems that this method permits the detection of an enzyme defect in the great majority of carriers of hereditary galactosæmia.

Note added in proof : A paper dealing with galactosæmia carriers has recently appeared (Brettauer *et al.*, *Proc. U.S. Nat. Acad. Sci.*, **45**, 328 ; 1959) which describes preliminary results obtained with a similar modification of our diagnostic methods[2], namely, shorter incubation time and higher substrate concentrations. Values for transferase activity in hæmolysates ranging between 4·8 and 8·1 μmoles/hr./gm. cells are reported. In a smaller survey I found values ranging between 4·0 and 5·8 μmoles/hr./gm. (unpublished work).

We also agree with Brettauer *et al.* that the modified diagnostic method makes it possible to find markedly lower enzyme values in hæmolysates from parents of galactosæmic children. I have found values as slow as 1·2–2·2 μmoles/hr./gm. cells. In spite of these differences we cannot recommend the "one point method" for use in the diagnosis of individual carriers. The manometric method as described by Kirkman gives a guarantee that one is really dealing with zero-order kinetics and we believe that at the present time it is the only test which can be used in the diagnosis of carriers in families in which galactosæmia has not been observed before. A detailed discussion of these problems will be given elsewhere.

Gene Action in Erythrocyte Deficiency of Glucose-6-phosphate Dehydrogenase : Tissue Enzyme-Levels

THE susceptibility to increased hæmolysis following ingestion of such agents as primaquine, naphthaline, nitrofurans, other drugs and the fava bean is associated with intrinsic defects in erythrocyte metabolism. These defects include a lower concentration of reduced glutathione[1], instability of reduced glutathione during incubation of the cells with acetylphenylhydrazine[2], and a deficiency in glucose-6-phosphate dehydrogenase[3]. Recent studies have suggested that this erythrocyte enzymatic deficiency is genetically determined, and inherited as a sex-linked characteristic of intermediate dominance[4–6].

In this investigation, it has been found that subjects with an erythrocyte deficiency of glucose-6-phosphate dehydrogenase have normal levels of this enzyme in their leucocytes. In addition, two subjects with markedly deficient erythrocyte glucose-6-phosphate dehydrogenase did not have a similarly decreased level of this enzyme in their liver.

Leucocytes were separated from venous blood by a method of dextran flotation which yields a white blood cell preparation contaminated with fewer than 5 red cells for each leucocyte[7]. This degree of contamination by red cells does not affect the assays of leucocyte enzyme. The leucocytes were suspended in approximately 20 vol. of isotonic potassium chloride buffered at pH 7·4 and disrupted by freezing and thawing three times. Leucocyte counts were performed prior to, and following, this procedure to ensure that assays were performed only on samples in which more than 90 per cent of the white blood cells were destroyed. Liver tissue was obtained by surgical biopsy through an abdominal incision. This tissue was homogenized and resuspended in isotonic potassium chloride buffered at pH 7·4. The erythrocytes were prepared as previously described[8]. Glucose-6-phosphate dehydrogenase, 6-phosphogluconic dehydrogenase and purine nucleoside phosphorylase were assayed by techniques described elsewhere[8].

In subjects whose red cells were markedly deficient in glucose-6-phosphate dehydrogenase, the leucocyte content of this enzyme was not significantly different from that in leucocytes of the control group (Table 1). Glucose-6-phosphate dehydrogenase activity was markedly higher (on a per 10^9 cell basis) in leucocytes than in erythrocytes. No significant differences were found in purine nucleoside phosphorylase activity of leucocytes or of erythrocytes of control subjects compared with persons with red cells deficient in glucose-6-phosphate dehydrogenase.

Table 1. GLUCOSE-6-PHOSPHATE DEHYDROGENASE ACTIVITY IN LEUCOCYTES AND RED CELLS OF CONTROL SUBJECTS AND PERSONS WITH A DEFICIENCY OF THIS ENZYME IN THEIR CIRCULATING ERYTHROCYTES

Subjects	Number	Leucocytes*	Red cells
Control	31	37·3 ± 5·8	0·49 ± 0·11
Deficient red cell *G-6-P.D.*†	14	36·8 ± 1·8	0·07 ± 0·01

* The unit of enzyme activity is expressed as the change in optical density per min. per 10^9 cells (△ opt. dens./min./10^9 cells). The mean values + or − one standard deviation are given.

† *G-6-P.D.*, glucose-6-phosphate dehydrogenase. All subjects included in this group had erythrocyte glucose-6-phosphate dehydrogenase levels below three standard deviations of the mean for the control group.

In 4 control subjects the level of glucose-6-phosphate dehydrogenase in liver was 0·081, 0·060, 0·58 and 0·088 units (change in optical density units per min. per mgm. liver nitrogen), respectively. Two subjects with erythrocyte glucose-6-phosphate dehydrogenase deficiency had levels of this enzyme in liver tissue of 0·052 and 0·040 units. 6-Phosphogluconic dehydrogenase activity in the liver of these subjects were 0·15 and 0·13 units compared with levels of 0·12, 0·17, 0·13 and 0·20 units in the control subjects, respectively.

These findings are of importance with respect to identification of the primary action of the genetic factor responsible for the deficiency in glucose-6-phosphate dehydrogenase in red cells of 'drug-sensitive' subjects. If the erythrocyte enzyme deficiency resulted from the direct action of a gene locus, all tissues of the affected organism might be expected to exhibit the lowered enzyme activity. The present studies suggest that erythrocyte glucose-6-phosphate dehydrogenase deficiency is not a primary but a more remote consequence of the presence of a genetic defect. No evidence for a glucose-6-phosphate dehydrogenase inhibitor was found in these red cells[9]. There is little or no protein synthesis in the mature erythrocyte[10,11]. As normal red cells age *in vivo*, there is a decrease in glucose-6-phosphate dehydrogenase activity[12]. A deficiency in erythrocyte dehydrogenase might result from an action of the gene affecting the turnover or stability of this enzyme in a manner such that its activity decreases more rapidly than normal as the red cell ages *in vivo*. Studies on the effect of age on glucose-6-phosphate dehydrogenase in erythrocytes of subjects whose red cells are deficient in this enzyme have revealed that young red cells have markedly higher activities than older cells[9].

Ageing of Human Cartilage

IN a recent study of human costal cartilage, the isolation of kerato-sulphate in addition to chondroitin sulphate was reported in two cases of Marfan's syndrome and in two young adults free of skeletal abnormalities[1]. In earlier work on hyaline mammalian cartilage, including that of new-born infants, no keratosulphate fraction had been encountered[2]. Moreover, rib cartilage of the new-born yielded only chondroitin-4-sulphate (*A*), while in the adult the fraction was predominantly chondroitin-6-sulphate (*C*)[3]. These findings, as well as the demonstration of a shift from D-galactosamine to glucosamine with increasing age in epiphyseal human cartilage[4], suggested a study of the distribution of chondroitin sulphate and keratosulphate in rib cartilage of various age-groups.

Human rib cartilage was obtained at unselected autopsies (we thank the Department of Pathology for its collaboration in this connexion). The age ranged from new-born to 74 years. The ribs were cleaned of extraneous tissues, bony parts and perichondrium, and dried in acetone. The dried tissue was homogenized, digested with 'activated' commercial papain[5] at 70°C. (Scott, J. E., personal communication) and, after further purification, the acid mucopolysaccharides were fractionated and analysed for nitrogen, hexosamine, uronic acid, hexose and sulphate. A quantitative separation of chondroitin sulphate and keratosulphate was not attempted since in our experience separation of keratosulphate from chondroitin-6-sulphate has only been possible after enzymatic digestion of the latter with testicular hyaluronidase. The chondroitin sulphate and keratosulphate content of the fractions were calculated from the carbazole and anthrone values of the isolated fractions.

The chondroitin sulphate of the fractions as per cent dry weight of cartilage is shown in Fig. 1. The chrondroitin sulphate content appears to decrease

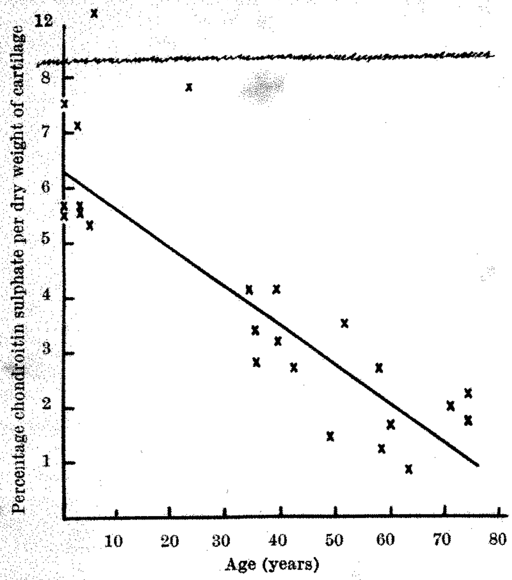

Fig. 1. Chondroitin sulphate content as percentage of dry weight of rib cartilage in relation to age

linearly with age. Keratosulphate was negligible or absent in the very young. It appears to reach a plateau at 20–30 years and to remain constant to the greatest ages investigated, where it represented approximately 50 per cent of the total mucopolysaccharide. When the ratio of keratosulphate to the total mucopolysaccharide is plotted against age, a linear increase is obtained as shown in Fig. 2. In this curve, the two cases of Marfan's syndrome (encircled crosses) fall within the upper range of the normal. Furthermore, costal cartilage from a young cow and a young pig, and tracheal cartilage from a young cow demonstrated similar ratios of keratosulphate to total mucopolysaccharide as do immature human beings.

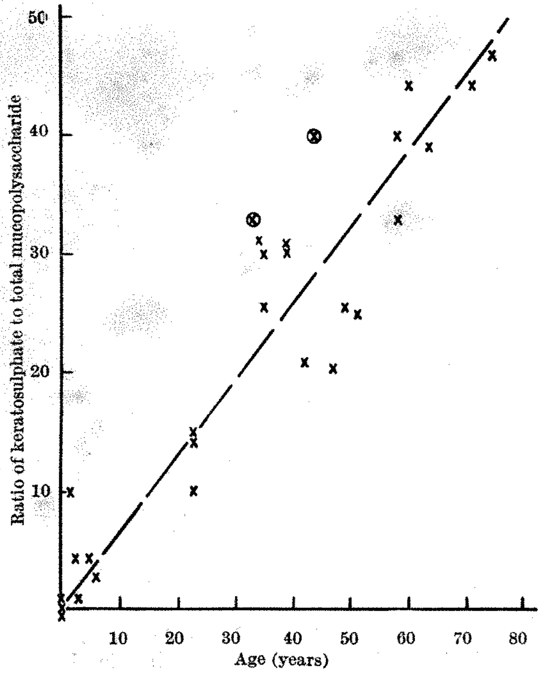

Fig. 2. Ratio of keratosulphate content to total mucopolysaccharide of rib cartilage in relation to age

Clinically, no correlation was found with sex (2/3 male, 1/3 female), with presence and degree of arteriosclerosis, or the state of nutrition (judged by degree of wasting as noted at autopsy). It may also be of interest that two of the subjects were on steroid therapy for more than two years, one had moderate osteoarthritis, one 34-year-old had bone disease and mild diabetes secondary to Cooley's anæmia.

The rib cartilage appears to be a tissue eminently suited for studies on ageing because it is less affected than other tissues by mechanical stresses, by the repeated insults of infection, and by the nutritional status. While the decrease in chondroitin sulphate content is continuous from birth to old age, the keratosulphate content increases to a plateau, which appears to be maintained even in senescence. The process of change with time in cartilage is thus more comparable to differentiation rather than to degeneration usually associated with ageing. It will be of interest to determine whether the time-schedule apparently inherent in this tissue can be influenced experimentally.

Salt Concentration and Fibrinolytic Activity

THE observation of gross spontaneous lysis in pathological states presents little difficulty, so long as there is some fibrinogen left to form an observable clot; but there is still no satisfactory method of assessing the normal blood fibrinolytic activity. The different test systems all disturb the balance of the fibrinolytic system, for example, by dilution, fractionation or introduction of abnormal clotting systems or change of *p*H. It is still debatable whether any method even approaches the state of affairs in a normal vessel, still less that in a thrombotic case where deposition of fibrin probably leads to local absorption of fibrinolytic components so that active enzyme is produced locally and clot lysis facilitated. This latter aspect is not directly approachable by *in vitro* methods; but it draws its reactants from the circulating blood, though in injury or anoxia tissue factors are also important, and so one aspect of the body's ability to deal with a clot is reflected in the blood fibrinolytic activity.

By apparently minor changes in the experimental conditions enormous variations can be produced in the fibrinolytic activity of the same blood sample. To compare results it is necessary to have a rigidly standardized assay system, and sufficient attention

Table 1. EFFECT OF VARYING SODIUM CHLORIDE CONCENTRATION ON PLASMA FIBRINOLYTIC ACTIVITY BY PARTIAL LYSIS METHOD

Plasma	Sodium chloride in reaction mixture (per cent)	6-hr. lysis	24-hr. lysis
1	0	14·5	100
	0·3	75	100

	1·0	0	97
2	0	50	100
	0·25	96	100
	0·5	26	100
	0·75	3	80
	1·0	0	4·5

Table 2. LYSIS TIMES (MIN.) OF BOVINE FIBRINOGEN BY STREPTOKINASE-ACTIVATED HUMAN PLASMA

Sodium chloride in reaction mixture (per cent)	Plasma 1	Plasma 2	Plasma 3
0	49	42	43·5
0·2	17	21	21·5
0·4	14	18	18
0·6	15	17·5	19·5
0·8	18	20	21
1·0	28·5	24	31

has not been paid to the effect of salt concentration. We show here some typical results of varying the salt concentration on the fibrinolytic activity of fresh, cold-collected, citrated human plasma as measured by the partial lysis method (Table 1) and on the total potential fibrinolytic activity as measured by streptokinase activation followed by lysis of bovine fibrin (Table 2).

Further experiments have shown that this effect is also obtained with salts other than sodium chloride, and there appears to be a relationship between fibrinolytic activity and the ionic strength of the reaction mixture. These results will be reported fully elsewhere.

Characterization of a Second Yellow Compound from *Drosophila melanogaster*

Hadorn and Mitchell[1] demonstrated by simple chromatographic techniques the presence of two yellow, yellow-fluorescent compounds in *Drosophila melanogaster*. Both these compounds are accumulated in the *sepia* mutant, and one of them (*F* 1 5), which is by far the major component, has been isolated in crystalline form[2]. A structure has been postulated for it[3], although this has had to be modified recently in the light of some new experiments on the compound to be described in this communication. The second component (*F* 1 7) is present in extremely small amounts even in the *sepia* mutant, and at such low levels it is very sensitive to light. However, we have succeeded in isolating a small amount of this material in crystalline form and have been able to demonstrate that it is indistinguishable from a yellow compound (compound *A*) which is found in comparatively large quantities in the blue-green alga, *Anacystis nidulans*[4,5].

A 6 per cent trichloracetic acid extract of 30 gm. of flies (*D. melanogaster*; mutant *sepia*) was passed through an acid-washed 'Florisil' column. The yellow fluorescent materials were concentrated in a band at the top of the column, and after the column had been thoroughly washed with dilute acetic acid and water, this band was eluated with 20 per cent aqueous acetone. The eluate was concentrated and then streaked on heavy filter paper (Whatman No. 17). A descending chromatogram was developed with butanol/acetic acid/water (4 : 1 : 1), and the faster-moving yellow compound was collected as a fraction when the solvent was allowed to drip off the paper. After evaporation of this fraction to dryness in the dark and *in vacuo*, a solution of the residue was again passed through a 'Florisil' column. The yellow eluate obtained by washing this with 20 per cent acetone was evaporated to small bulk, when the product crystallized in tiny yellow needles.

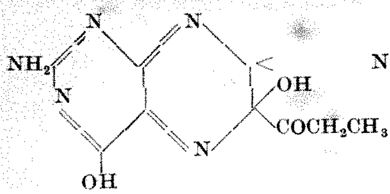
The absorption spectrum of this material was identical with that of the main yellow substance from *Drosophila* and with compound *A* from *Anacystis nidulans*[2,4]. Its paper chromatographic behaviour was identical with that of compound *A* (Table 1). Furthermore, on decomposition with bromine water, a colourless, blue-fluorescent material was obtained which again was identical paper chromatographically and spectroscopically with the analogously prepared derivative of compound *A*. Lastly, in alkaline solution, this yellow compound was readily oxidized to xanthopterin—again[5] a characteristic reaction of compound *A*.

Table 1

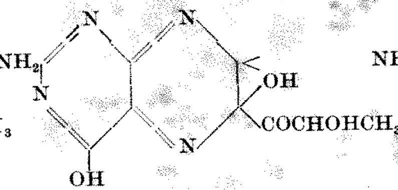
Solvent	R_F			
			Bromine decomposition products	
	Compound *A*	*F* 1 7	Compound *A*	*F* 1 7
n-Propanol/1 per cent ammonia (2 : 1)	0·78	0·78	0·82	0·82
n-Butanol/acetic acid/water (4 : 1 : 1)	0·75	0·75	0·73	0·73
n-Butanol/methylethyl ketone/ammonia/water (5 : 3 : 1 : 1)	0·21	0·21	0·23	0·23
sec.-Butanol/formic acid/water (8 : 2 : 5)	0·32	0·32	0·27	0·27

Drosophila melanogaster, then, contains as a normal constituent, albeit in very small amount, the same yellow pteridine as is found in *Anacystis nidulans* and which is probably xanthopterin B_1[6] and bufo-yellow 2[7]. The structure proposed for this compound (I) and the revised structure for the main yellow pigment from *Drosophila* (II), show that they are quite simply related, I being the deoxy derivative of II. It is not difficult to visualize how the two side-chains on these compounds could arise from a common precursor, the dihydroxypropyl side-chain of biopterin (III), by simple dehydration or oxidation. Whether these reactions occur biologically remains to be discovered.

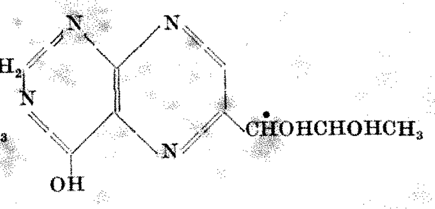
The implications of these findings for the structures of the red eye pigments of *Drosophila* might also be outlined. There are at least three red eye pigments[8]. The presumed precursor for these is the main yellow compound accumulated by the *sepia* mutant which has no red eye pigments. It is possible, however, that the three red compounds arise from three different, but closely related, yellow precursors, two of which are mentioned in this communication, a third remaining to be discovered (a third possible compound, for example, would be one containing a $CH_2OHCHOHCO$— side-chain at the 6-position.



I



II



III

This would be reasonable in view of the similar biological activity of biopterin and its trihydroxypropyl analogue[9]). A simple chemical change, for example hydroxylation of the 7-position, or further oxidation would then convert these yellow compounds into the closely related red pigments. Further work on this aspect and on the biochemistry of these compounds is being undertaken.

Activity of 10-Hydroxydecenoic Acid from Royal Jelly against Experimental Leukæmia and Ascitic Tumours

Despite many investigations of royal jelly[1], its chemistry and pharmacological activity have not been completely established. As part of a long-term study on the chemistry and biological activity of royal jelly[2] we have recently investigated its possible anti-tumour properties. In this communication we wish to report that admixture of royal jelly with tumour cells before inoculation completely suppresses the development of a transplantable mouse leukæmia and the formation of ascitic tumours in mice. Fractionation studies have established that this anti-tumour activity resides in the main fatty acid of the royal jelly—10-hydroxydecenoic acid.

Anti-leukæmia studies were carried out by the method of Burchenal *et al.*[3] using female mice, 5–6 weeks of age, of the *AKR* strain. Cell suspensions were prepared in Gey's balanced salt solution[4] from the spleen of a mouse dying from spontaneous leukæmia. To these suspensions were added whole royal jelly, various fractions of royal jelly, or a standard citric acid or phosphoric acid buffer. The *p*H of each mixture was determined. The mixture was then shaken and immediately injected subcutaneously at a dose of 0·2 ml. per mouse. Each mouse received 2–5 million cells, as measured by direct hæmacytometer counts. Mixing of the tumour cells with test materials prior to injection has been employed in other investigations of a similar nature[5].

The criterion used in these experiments was survival: the mice either developed leukæmia or were protected. Each dead mouse was examined both grossly and microscopically by liver and spleen section to determine the extent of leukæmia infiltration. First transfers from mice with spontaneous leukæmia caused death in approximately 50 days; but successive transfers caused death more rapidly, in some cases within 16 days. The results of the anti-leukæmia experiments are summarized in Table 1.

Table 1. EFFECT OF ROYAL JELLY AND 10-HYDROXYDECENOIC ACID ON SURVIVAL OF MICE WHEN MIXED WITH LEUKÆMIC OR ASCITIC TUMOUR CELLS PRIOR TO INJECTION

Mixture*	No. of mice	*p*H of mixture	Protection†
Leukæmic cells plus:			
30 mgm. fresh royal jelly	41	4·2–4·8	+
15 mgm. fresh royal jelly	14	5·5–6·5	–
1·5 mgm. 10-hydroxydecenoic acid	32	4·2–4·8	+
1·0 mgm. 10-hydroxydecenoic acid	12	5·1–6·1	–
Citric acid buffer only	7	4·2	–
Phosphoric acid buffer only	16	5·3–5·8	–
2·0 mgm. 10-hydroxydecenoic acid	20	4·7–5·6	+
2·0 mgm. 10-hydroxydecenoic acid	26	6·1–7·3	–
6C3HED lymphosarcoma cells plus:			
100 mgm. whole royal jelly	212	5·9–6·1	+
100 mgm. whole royal jelly	52	7·2	–
1·0 mgm. 10-hydroxydecenoic acid	28	4·2	+
1·0 mgm. 10-hydroxydecenoic acid	28	6·9	–
0·6 mgm. 10-hydroxydecenoic acid	24	4·2	–
Buffer only	64	4·2	–
Buffer only	278	6·9–7·4	–

* Materials indicated as mgm. per ml. of cell suspension. In leukæmia experiments, each mouse received 0·2 ml. of mixture; in ascites experiments, each mouse received 0·5 ml. of mixture.

† +, Survival beyond six months. –, 100 per cent death in 21–54 days with the leukæmic cells and 100 per cent death in 12–15 days with *6C3HED* cells.

Anti-tumour studies were conducted in three lines of ascitic tumours: the *6C3HED* lymphosarcoma, the *TA3* mammary carcinoma, and the Ehrlich carcinoma. Initially, these tumours were carried in the tumour-specific mouse strains; but in later experiments all three tumours were carried in the non-specific Connaught mouse line, following the freezing procedure of Morgan *et al.*[6]. Ascitic cells were harvested by intraperitoneal puncture, mixed with 2 vol. water to lyse any red cells present, centrifuged, and resuspended in Hanks's balanced salt solution[7] to the desired cell count. This suspension was mixed with the appropriate amount of whole royal jelly or fraction of royal jelly at different *p*H-levels, and was then administered intraperitoneally to large groups of mice (10–30) in 0·5-ml. doses. Each mouse normally received 5–8 million tumour cells; but in some cases doses of 10–20 million cells were used.

As in the anti-leukæmia experiments, the criterion was survival: control mice died from ascitic tumours in less than 14 days, while mice receiving appropriate mixtures of cells and royal jelly all failed to develop tumours. Protected mice were kept under observation for 90 days after death of the control mice. They were then killed, and random individuals autopsied to confirm the absence of tumours. The results of these studies are also summarized in Table 1. To conserve space, only experiments with the *6C3HED* lymphosarcoma are reported, although identical results were obtained with the other two tumours, and only the active fraction, 10-hydroxydecenoic acid, is listed.

The results summarized in Table 1 indicate that 30 mgm. of fresh whole royal jelly or 1·5 mgm. of 10-hydroxydecenoic acid per ml. of cell suspension inhibited completely the development of transplantable leukæmia in *AKR* mice. This effect was obtained only when the active material was mixed with the leukæmic cells prior to administration. Attempts to demonstrate protection after tumour implantation or by separate administrations of royal jelly and leukæmic cells have as yet been unsuccessful. The anti-leukæmic activity was demonstrated only at *p*H values below 6·0; but leukæmic cells alone, buffered to the same *p*H-range, caused death from leukæmia within the normal time.

Results of the anti-ascites experiments (Table 1) are very similar to the anti-leukæmia observations. Both whole royal jelly and its constituent 10-hydroxydecenoic acid prevent the development of ascitic tumours in mice. Somewhat higher concentrations of material are required than with the transplantable leukæmia. Approximately 100 mgm. of fresh whole royal jelly or 1·0 mgm. of 10-hydroxydecenoic acid per ml. of cell suspension were required for complete protection. At lower dosages, development of the ascitic tumours was delayed for 5 to 6 days. Afterwards, rapid tumour formation and death of the mice ensued in all cases. As in the leukæmia experiments, an acid *p*H and admixture of the royal jelly or fatty acid with the tumour cells prior to injection were required to demonstrate the activity.

The role of royal jelly in the development of queen bees has stimulated many investigations into its possible therapeutic role in many human diseases, including leukæmia[8]. In most instances, the reports have been incomplete and difficult to assess. The present report appears to be the first unequivocal demonstration of an anti-tumour activity in royal jelly. The results have been confirmed repeatedly on nearly 1,000 mice during a 2-year period, and show a striking effect: either all the mice die quickly or all survive. Two groups of mice which received tumour cells plus royal jelly remained alive and healthy more than 12 months after inoculation, while sister mice which received the same number of tumour cells without royal jelly died within 12 days.

The royal jelly ether-soluble fatty acid used in this study was isolated originally by Townsend and Lucas in 1940[2] and was later identified by Butenandt[9] as 10-hydroxydecenoic acid. The dependence of its biological activity on *p*H suggests that only the undissociated fatty acid is effective. Identification of the active constituent of royal jelly as a fatty acid is of interest in view of the recent demonstration[10] that ascitic tumour cells can metabolize such compounds readily.

Further studies are in progress to determine whether the active material causes death of the tumour cells before inoculation, as reported previously by Burchenal *et al.*[11] with certain chemotherapeutic compounds. The study has been extended to an investigation of structural derivatives of 10-hydroxydecenoic acid and closely related compounds.

Serotonin and Change of Colour in Frogs

It is well known that intermedin, a secretion of the pituitary, is responsible for the dispersion of the pigment in the melanocytes of frogs. The identity of the secretion has remained a mystery; indeed, there are few compounds capable of causing the darkening of hypophysectomized frogs.

Recent experiments in this laboratory have revealed that the indolamines tryptamine and 5-hydroxytryptamine (serotonin) disperse the pigment in the melanocytes of hypophysectomized specimens of *Rana pipiens* when injected into the dorsal lymph space. The effect, recorded by photographing an area of the web of the foot at intervals after the injection, is short-lived; dispersion of the pigment is apparent within 15 min. after injection and lasts an additional 15–30 min. At the end of this time, the pigment returns to its normal concentrated condition, but some reinforcement of the effect can be obtained by a second injection while the pigment is dispersed. The degree of dispersal achieved during these experiments does not approach that encountered in a fully darkened frog in Nature, but the effect is definite and striking. The chemicals were administered as solutions in Ringer's solution of tryptamine hydrochloride and 5-hydroxytryptamine creatinine sulphate in doses ranging from 10 to 1,000 μgm.

Other compounds with pharmacological properties similar to those of serotonin have been tested and found to exert no melanophorotropic effect. Thus, in the present study, histamine acid phosphate and acetylcholine bromide failed to disperse the pigment, and Hogben and Winton[1] found that tyramine was without effect.

Extracts of frog pituitary gland in Ringer's solution produce total dispersion of the pigment lasting several hours when injected into hypophysectomized frogs. Injection of 100 µgm. of lysergic acid diethylamide, considered to be an inhibitor of serotonin, with the pituitary extract results in a return of the pigment to the contracted condition much more quickly. This experiment can be regarded as providing indirect evidence that serotonin is involved in the darkening process. A similar antagonism between serotonin and lysergic acid has already been reported for the chromatophores of fish[2].

Using an extraction technique based on that of Weissbach, Waalkes, and Udenfriend[3], extracts have been prepared from frog pituitary glands. When such extracts are evaporated to dryness to eliminate the toxic organic solvents involved in the extraction process, and the residue is dissolved in Ringer's solution, they exhibit melanophorotropic activity in the same way as the indolamines when injected into hypophysectomized frogs. On the other hand, an extract prepared from frog nerve cord has no effect.

However, ultra-violet absorption studies with these extracts have demonstrated that the material is not serotonin. The hypothesis that it may be a derivative or precursor of 5-hydroxytryptamine is under examination in this laboratory.

I am indebted to Dr. W. E. Beckel, in whose laboratory this work is being done, for his interest and encouragement, and to the National Research Council for financial support.

Lack of Effect of Histidine on Rabbit Atheromatosis

CHIMAKADZE[1,2] has published an interesting report on the treatment with histidine of rabbits fed with cholesterol. He claimed that daily administration of 80 mgm. of histidine for 20 days lowered the serum cholesterol-levels by 1,000–1,300 mgm. per cent and markedly diminished the deposition of aortic lipids. In view of the potential importance of these claims we decided to repeat and extend the experiment.

Twenty-one white New Zealand rabbits from four litters (litters I, II, III contained 5 animals, litter IV, 6 animals) were divided into five groups. Each group was composed of one member from each litter; the fifth group had 2 litter mates. Groups 1 and 2 were given 100 gm. 'Purina' rabbit chow containing 0·375 gm. cholesterol a day. Groups 3 and 4 received the same amount of chow containing 0·750 gm. cholesterol a day. Group 5 served as a control to check possible hereditary hypercholesterolæmia or the presence of spontaneous aortic lesions. The animals received the diets for 92 days, and food consumption records were obtained for each animal. After the first 50 days the rabbits of groups 1 and 3 were given by stomach tube 80 mgm. of histidine in 4 ml. water a day. (DL-Histidine hydrochloride was chosen since Chimakadze did not specify the type of histidine used, and since experiments in rats[4] and mice[5] have shown that D-histidine is converted to L-histidine.) The animals of groups 2 and 4 were given by stomach tube 4 ml. of water only. Serum cholesterol was determined by the method of Pearson *et al.*[3] before starting the cholesterol diet, every 10 days during the first 50 days, and once each week during the remainder of the period. The evaluation of the degree of the aortic lipid deposition was made by gross observations of the excised aortas according to a standard scale employed in our laboratory.

Animals fed with the lower cholesterol diet showed the same degree of slight atheromatosis, those fed with the higher cholesterol diet the same degree of more severe lesions into the aortic wall. Thus our results have shown no difference in the extent of lipid deposition in the aortic wall of the histidine-treated group when compared with the animals receiving water. The serum cholesterol-levels showed a gradual increase from the initial levels of 117 ± 9 mgm. per cent to final levels of 363 ± 171 mgm. per cent on the 0·375 gm. cholesterol intake and 1,073 ± 115 mgm. per cent on the 0·75 gm. cholesterol intake on the fiftieth day.

During the 22 days of histidine administration, when Chimakadze claimed a decrease of serum cholesterol by 50 per cent, 5 out of 7 of our water-treated group and 5 out of 6 of our histidine-treated group showed further and similar increases in their serum cholesterol-levels. We did not note any differences in cholesterol-levels in the different groups up to 37 days of histidine treatment, which was nearly twice as long a time as that employed by Chimakadze. At that time some of the histidine-supplemented animals developed some anorexia and the experiment was terminated. The animals in the control group were free from an elevation of the blood cholesterol-level or aortic fat deposits.

On the basis of our results we cannot explain the pronounced effect of histidine claimed by Chimakadze. The administration of 80 mgm. of histidine does not increase the total histidine intake significantly, since the animals already received 430 mgm. of histidine daily ('Purina' rabbit chow contains 0·43 per cent L-histidine; personal communication from P. E. Kifer, Ralston Purina Company.) Perhaps the Russian diets, which are not specified by the author, were marginal in histidine content. It is also possible that in the Russian experiment the administration of histidine altered the food intake, a factor which was controlled in our experiment but not mentioned by Chimakadze. A third possible difference may, of course, be in the strain of the animals.

In conclusion, it is apparent that the alleged lowering of cholesterol and anti-atherogenic activity of histidine could not be demonstrated under the conditions of our experiment.

Reserpine Derivatives with Specific Hypotensive or Sedative Activity

RECENTLY it has been reported, by Ciba Laboratories[1,2], that two reserpine analogues show more specific effects than reserpine. Methyl-18-O(3-NN-dimethylaminobenzoyl)reserpate (or *SU* 5171) exhibits sedative activity, while carbethoxysyringoylmethylreserpate (syrosingopine or *SU* 3118) is effective in decreasing blood tension (see formulæ).

These results prompted us to investigate, on a quantitative basis, the difference between the two new compounds and reserpine during several tests.

Our experiments were carried out on Sprague–Dawley rats of both sexes, weighing about 200 gm. The compounds were injected intraperitoneally 4 hr. before the determinations reported here were made. Brain serotonin was assayed according to Bogdanski *et al.*[3] by the spectrofluorimetrical method. Blood pressure was recorded kymographically, by a Sanborn electro-manometer, following cannulation of the carotid artery, the animal being narcotized with ethyl urethane (100 mgm./100 gm. intraperitoneally). Body temperature was measured with an electrical thermometer introduced in the rectal cavity. Sleeping time after barbiturates was evaluated by injecting intraperitoneally 20 mgm./kgm. nembutal. Sedation was judged by observation of behaviour, responsiveness to commands and reduced interest in surroundings.

The results obtained are summarized in Table 1.

From these results it appears quite evident that *SU* 3118 and *SU* 5171 have, at least in rats, a specific effect. In fact, while for reserpine the minimal hypotensive dose and the minimal sedative dose are very close, for *SU* 3118 and *SU* 5171 they are clearly differentiated. In particular, for *SU* 3118 the onset of sedation occurs at 30 mgm./kgm., while the fall of blood pressure begins at 0·95 mgm./kgm.; for *SU* 5171 the two activities are present respectively at 5 mgm./kgm. and more than 30 mgm./kgm., the highest dose tested. Further experiments indicate that the sedative activity of *SU* 5171 (7·5 mgm./kgm.) is less persistent than the respective activity of reserpine (2·5 mgm./kgm.), since it disappeared after 36 hr.

In agreement with a previous paper of ours on reserpine[4], for these new compounds also good correlation is shown between sedation, depletion of brain serotonin, fall in rectal temperature and increase in nembutal sleeping time. In particular the

The number of animals used is given in brackets.

release of brain serotonin, induced only by the compound provided with sedative activity, supports Brodie's assumption[5] on the importance of depletion of brain amines in explaining reserpine sedation. On the contrary, the decrease in brain serotonin does not seem significant in explaining the hypotensive effect of reserpine. The possibility that *SU* 3118 is ineffective on brain serotonin for a poor penetration into the brain is questionable, since in some experiments we observed no changes in intestinal serotonin after 20 mgm./kgm., while reserpine (2·5 mgm./kgm.) or *SU* 5171 (7·5 mgm./kgm.) determined a depletion of about 40 per cent. The use of these new compounds, besides their clinical importance[6], seems to be very valuable for a better understanding of the mechanism of the action of reserpine in determining both hypotension or sedation.

For this research we gratefully acknowledge the gift of *SU* 3118 and *SU* 5171 from Dr. A. J. Plummer, of Ciba Laboratories, Summit (N.J.), and of reserpine from Dr. V. Ghetti, of Ciba s.p.A., Milan.

Differences in Mechanism in Staining Reactions for Mast Cells

Mast cells are usually identified histochemically by the use of aldehyde fuchsin[1], Hale[2] or Rinehart[3] stain, or by the metachromasia they exhibit with certain basic dyes. All these methods demonstrate mucopolysaccharides, although differences in the degree of staining of various mucopolysaccharides with the several methods have been noted[4]. Peracetic acid oxidation (Greenspan's mixture 30 min., 25° C.)[5] of tissue sections has been found to induce staining of certain normally unreactive substances with aldehyde fuchsin[6–8], and to alter the susceptibility of oxytalan fibres to hyaluronidase, lysozyme and elastase[7]. During the course of investigations of mucopolysaccharide reactivity after peracetic acid oxidation, an interesting change was observed in mast-cell cytoplasms. Peracetic acid oxidation followed by digestion with enzymes which hydrolyse mucopolysaccharides resulted in diverse staining reactions with the above three methods for mucopolysaccharides.

The skin, tongue and other organs of adult *BALB/c* strain mice were used. Fresh 2-mm. thick specimens were taken and immediately placed in Lillie's[5] aqueous neutral calcium acetate formalin for 24 hr. at room temperature. The specimens were then washed, dehydrated, blocked in paraffin, and sectioned at 6μ.

Mast cells in control sections stained with either azure *A* (0·5 per cent in aqueous 0·2 *M* phosphate buffer *p*H 4, 30 min., 25° C.), aldehyde fuchsin or the Hale stain reacted brilliantly either with or without previous oxidation of tissue sections with peracetic acid. Peracetic acid generally enhanced the subsequent staining reactions. However, if sections were oxidized with peracetic acid and then digested with either β-glucuronidase (Nutritional Biochemicals Corp., 15 mgm. : 50 ml. 0·1 *M* acetate buffer *p*H 4·5, 24–48 hr., 37° C.) or lysozyme (Worthington, 5 mgm. : 30 ml. 0·2 *M* phosphate buffer *p*H 5·3 24–48 hr., 37° C.), no mast cells were affected by the Hale stain, and few with aldehyde fuchsin. The few that reacted with aldehyde fuchsin were only slightly stained. Nevertheless, all mast-cell granules and their cytoplasms remained strongly reactive with azure *A*; the staining reaction was only slightly reduced, if at all. Occasionally, testicular hyaluronidase (Nutritional Biochemicals Corp., 25 mgm. : 50 ml. 0·2 *M* phosphate buffer *p*H 6, 24–48 hr., 37° C.) would prevent the subsequent Hale staining reaction, but the results were erratic. No effect on any staining reaction was observed if sections were not oxidized with peracetic acid prior to the digestion step. Sections oxidized with peracetic acid and then incubated in the various buffer solutions for the same time-intervals stained with undiminished or nearly undiminished intensity. When peracetic acid-oxidized sections were incubated in either lysozyme or glucuronidase that had been boiled in its respective buffer for 5 min., the same results were achieved as with unboiled enzymes. This is consistent with a previous report that lysozyme retains full enzymatic activity after boiling in acid solution[9]. The effect of boiling on the enzymatic activity of glucuronidase has not been reported. Lysozyme was inactivated by boiling in alkaline buffer at *p*H 9 for 30 min. (confirming a previous report[9]), and mast cells reacted strongly with all stains after incubation in the usual manner with lysozyme treated in this fashion. Meyer *et al.* have reported the inhibition of lysozyme by iodine and hydrogen peroxide[9]. Lysozyme was almost completely inhibited by iodine (Lugol's 1 : 300 buffer), and moderately inhibited by hydrogen peroxide 30 per cent (1 : 15 buffer) as indicated by the nearly normal, and slightly diminished aldehyde fuchsin and Hale staining respectively of mast cells when incubated with lysozyme and inhibitor. Saccharic acid has been reported to inhibit glucuronidase[10]. Mast cells stained moderately with aldehyde fuchsin and the Hale method after incubation in glucuronidase with saccharic acid at 0·01 *M* concentration, but full staining was not achieved even after incubation with glucuronidase in saccharic acid at 0·1 *M* concentration, indicating moderate but not complete inhibition.

These results are compatible with the view that after peracetic acid oxidation, both glucuronidase and lysozyme enzymatically remove a component from mast cells that is stained with aldehyde fuchsin and the Hale stain, and that there remains a component inducing strong metachromasia with azure *A*. Since inhibitors which are not otherwise likely to alter the enzyme prevent the effect on the staining reactions, it is unlikely that the lack of staining with aldehyde fuchsin and the Hale stain in this case represents an uptake of basic protein by acid mucopolysaccharides rendering these groups unavailable to the stains. This type of blockage has been previously reported[11–13]. The reactions clearly demonstrate that although all the above three methods stain mucopolysaccharides, the granules and other cytoplasmic components of mast cells, the staining reactions are not equivalent and probably are not staining the same substance.

I wish to acknowledge especially the technical assistance of Mr. Clifton Link, jun.

PATHOLOGY

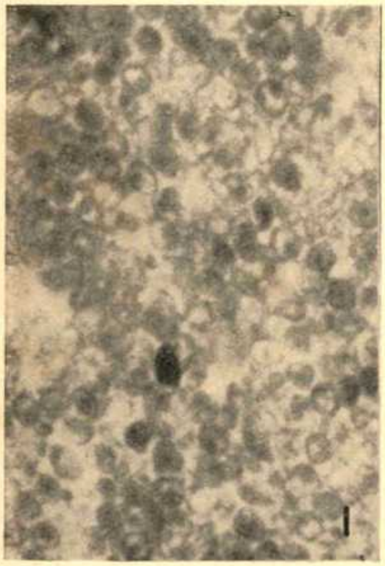
Purification of the Mouse Mammary Carcinoma Agent by means of a Fluorocarbon

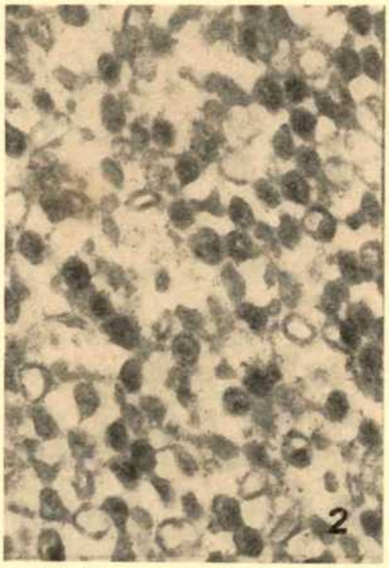
THE use of fluorocarbons for removing host cell components from aqueous suspensions leaving viral particles in relatively pure form in the aqueous phase was suggested by Gessler, Bender and Parkinson[1]. Epstein[2] has demonstrated the utility of this technique in the purification of vaccinia and the Rous sarcoma viruses.

Recently we have reported the identification of the mouse mammary carcinoma agent by correlation of its physical and biological properties making use of filtration through 'Gradacol' membranes, ionizing irradiation and free diffusion[3]. In addition, the structural development of the agent *in vitro* in tumour explants has been traced[4]. Since the fine structure of the agent is now believed to be established, it has become feasible to follow purification procedures by electron microscopic examination of thin sections of ultracentrifugalized pellets.

In a typical example, a spontaneous mammary carcinoma weighing 5·5 gm. from a mouse of the *R*III strain was minced and then homogenized in 40 ml. of a solution 0·15 *M* with respect to sodium chloride, 0·02 *M* with respect to sodium phosphate and 0·2 *M* with respect to sucrose (*p*H 7·4) and 20 ml. of 'Freon 113' or 'Genetron 226' ($CF_2Cl\text{-}CCl_2F$) (density 1·6). The homogenization was accomplished with a 'VirTis' homogenizer (The VirTis Co., Gardiner, N.Y.) run at 45,000 r.p.m. for 2 min. The whole fractionation process was carried out in the cold (0–5° C.). The homogenate was then centrifuged at about 300*g* for 1 min., which caused the emulsified 'Freon' to settle out as a gelatinous layer. The aqueous layer containing the virus was removed from above, mixed with half its volume of 'Freon', again emulsified with the 'VirTis' homogenizer for 2 min. and centrifuged at 300*g* for 1 min. The process was repeated five or six times until the supernatant aqueous layer became almost water-clear. As the soluble proteins and lipids are removed by the 'Freon', the amount of 'Freon' which may be emulsified becomes reduced and the excess will remain as clear liquid underneath.

After the last low-speed centrifugation, the supernatant fluid was spun at 3,000*g* for 20 min., and relatively large gelatinous pellets, presumed to be made up of 'Freon' micelles, were formed. The supernatant was then water-clear and contained the





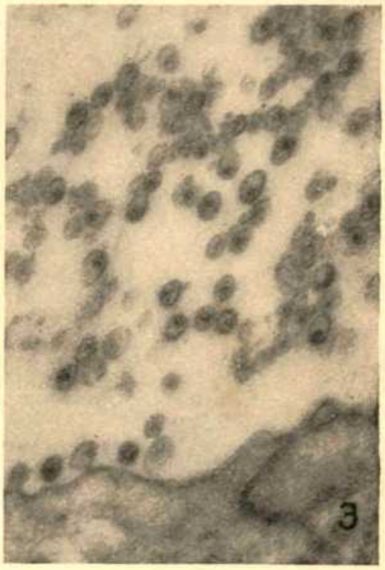


Fig. 1. Electron micrograph of sectioned pellet showing profiles of the milk agent. Since the thickness of the section is less than a third of the diameter of the particles, only segments of many spheres are caught in the section. (× 40,000)

Fig. 2. Electron micrograph of a section from another preparation where the bodies are not so closely packed and the contrast is better. (× 48,000)

Fig. 3. Electron micrograph of mammary carcinoma tissue showing the milk agent particles along the cellular membranes and lying free in the intercellular space. (× 35,000)

desired bodies, which were pelleted out at 100,000g in 1 hr. This small pellet was very white, but turned brown when fixed with 1 per cent buffered osmium tetroxide solution. The pellets obtained after centrifuging at 3,000g did not, on the other hand, turn brown in osmium tetroxide. The fixed pellets were prepared for electron microscopy in the usual manner employed for tissue. Electron micrographs of thin sections of final pellets are illustrated in Figs. 1 and 2. For comparison, Fig. 3 shows the appearance of particles in tumour cells recently identified as the milk agent[3,4].

We have used the same process for purifying the agent from the culture medium of explants of tumour fragments from the *R*III mice, as well as from the milk of these mice. The preparation from the milk was not so pure as those from either the tumours or the culture mediums. Milk is rich in non-viral particles, which are not easily separated by the procedure described here.

Profiles of the milk agent are easily recognizable in the electron micrographs. The characteristic structure of these particles consists of a dense nucleoid about 25 mμ in diameter contained within a membraneous sac about 100 mμ in diameter. The nucleoid occasionally appears centred, but more often it is eccentric, appearing near or in contact with the surrounding membrane. The membrane is 8–10 mμ thick and appears to be of the same structure and density as the membrane of the cells which liberate the bodies[3,4].

Impairment of Viral Hæmagglutination of Red Cells after Treatment with Formalin

IT was reported recently[1] that mouse cells treated with formalin were more readily agglutinated by some strains of myxoviruses than were untreated cells, and it was suggested that this finding might have general application.

We wish to report briefly that with some viruses and human red cells, the opposite holds good, and that agglutination may be abolished by formalin treatment.

Group O red cells were treated with formalin as described by Gold, Lockyer and Tovey[2]. They were incubated at 37° overnight, then washed three times in saline. Phosphate-buffered saline, pH 7·4, was used as a diluent in the hæmagglutination tests which were carried out in plastic plates at room temperature.

This experiment has now been repeated using the 6-hr. formalin treatment described by Fauconnier and Barua[1], but with phosphate-buffered saline instead of isotonic saline for suspending the cells and for the dilutions. The results were similar to the previous experiment and are given in Table 1.

Table 1. EFFECT OF TREATMENT WITH FORMALIN ON AGGLUTINABILITY OF RED CELLS

Virus strains	Reciprocal hæmagglutination titre		Ratio A/B
	Fresh cells (A)	Treated with formalin for 6 hr. (B)	
Myxoviruses			
Influenza *A* (Mel)	80	80	1
Influenza *B* (Lee)	40	30	1·3
Sendai	8	32	0·25
Columbia *SK**	20	20	1
Adenovirus type 9	6,400	300	21
ECHO viruses			
Type 10	96	< 1	>96
Type 11 (*U* virus[3])	512	<1	>512

* Sheep cells in veronal buffered saline used (ref. 4)

It will be seen that, with the myxoviruses and *Col SK* virus, the titres are either unchanged or enhanced, but that agglutination has been greatly reduced or abolished in the case of the adenovirus 9 and the two *ECHO* viruses tested. Other experiments showed that red cells treated with formalin failed to absorb *ECHO* 10 and 11 viruses, and absorbed adenovirus type 9 less well than untreated cells. Myxoviruses were absorbed equally well by treated and untreated cells. These findings support the view that myxoviruses and *Col SK* virus[4] react with similar red-cell receptors, and that these are distinct from those with which *ECHO* viruses[5] and adenoviruses react.

These results were obtained in the course of an investigation comparing the hæmagglutination reaction found in viruses of various groups and will be published in full later.

Ploidy of Primary and Metastatic Human Tumours

REPEATED observations conducted over many transplant generations on animal tumours have shown that the modal chromosome ploidy may change during the passages. This change is always toward the higher value of ploidy; changes in the opposite direction have never been observed[1].

Nothing is known about these events in the human tumours since transplantation of tumours from one human being to another is, of course, not feasible. Metastasis in human tumours, however, may be considered a type of self-autotransplantation. The objective of the present study was to compare the cell population ploidy of human primary tumours with that of their metastases. The evidence to be presented was collected from human tumours obtained at surgery (4 breast adenocarcinoma with axillary lymph node metastasis) and at necropsy (1 breast adenocarcinoma with liver and bone metastasis; 1 nasopharyngeal carcinoma with liver and adrenal metastasis).

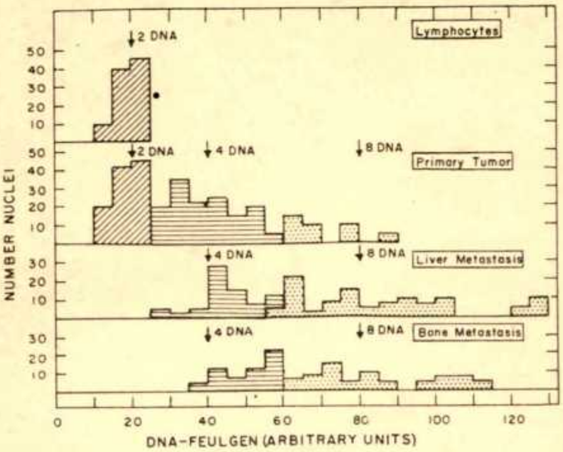

Fig. 1. Distribution in the single nuclei of the deoxyribonucleic acid–Feulgen material in one case of adenocarcinoma of the breast. The arrows correspond to the average value of the single modal class—2 DNA, 4 DNA, 8 DNA are the di-tetra-octoploid classes

With the microspectrophotometric technique, repeated absorption measurements of the deoxyribonucleic acid of single interphase nuclei were made at 546 mμ on Feulgen-stained sections. The product of extinction and volume was taken to be proportional to the amount of deoxyribonucleic acid per nucleus. The total number of nuclei measured for each primary tumour and its metastasis was approximately 500. The primary tumour, its metastasis, and the control lymph node were fixed together, embedded in the same paraffin block and prepared on the same slide. The positive correlation of the quantitative measurement of the deoxyribonucleic acid–Feulgen by microspectrophotometry with deoxyribonucleic acid measurement by ultra-violet microspectrophotometry, with biochemical analysis, and with chromosome counts have established the technique as a suitable method for the evaluation of the nuclear chromosomic set[2,3].

The distribution of deoxyribonucleic acid in the population of cell nuclei of a breast adenocarcinoma is shown in Fig. 1. The histogram shows a first modal class at the same position (2 DNA) for the control lymphocytes and primary tumour cell nuclei. This group of elements corresponds to the diploid class. The 4 DNA and 8 DNA class in the primary tumour nuclei population is an expression of the well-known hetero-polyploid chromosomic condition. The metastatic lesions, localized in the liver and bone (skull) are deficient in the diploid class in comparison with the primary tumour of origin.

The same behaviour was observed in four other cases when the metastatic growth in the lymph node was compared with the primary mammary adenocarcinoma. A similar lack of the diploid class was evident in the liver and adrenal metastasis of a nasopharyngeal carcinoma in contrast to the primary tumour where the diploid class is present. No significant differences were seen between the ploidy of the metastatic lesions in different organs of the same subject. The nuclear volumes of tumour cells were significantly greater in the metastatic lesions and the distribution of the volume estimations had a wider spread than the values found in the primary tumour.

It has been reported that nearly all tumour cell emboli are arrested in the vascular network of the first organ encountered, and that there the earliest and most numerous metastases develop. The concept that these arrested cells always lead to metastatic growth is not in accord with some experimental data from mouse and rat[4–7], with observations obtained from studies in human beings of cancer cells in the blood stream without recognizable metastases (Potter, J. F., and Malmgren, R. A., personal communication) and with the fact that the majority of the arrested emboli apparently fail to produce metastatic foci by extension and growth within the tissues[8–10]. This means that the number of fully established metastatic foci is much less than the number of tumour cells which enters the blood stream and has the opportunity of implantation in a given organ of a subject carrying a malignant tumour.

In the present study the infrequency of diploid cells in the metastasis, in comparison with the primary tumour, suggests the possibility of a cytogenetic basis for the phenomenon of metastasis. It is possible that all types of cells may be released from the tumour and circulate in the vascular or lymphatic stream, but when they become lodged only a few (the hetero-aneuploid) can develop and become established as metastatic loci. Another possible interpretation of the results is that only the heteroploid cells leave the tumour, embolize in the blood stream and establish secondary growths. Whatever the cause, the end-result is a cell population, in the metastasis, differing from the population in the primary tumour. This difference suggests that cells with a heteroploid chromosomic number have a greater capacity for survival and the establishment of metastatic foci when they are transferred to a new site and a new environment.

BIOLOGY

Infectious Ribonucleic Acid as Precursor of Tobacco Mosaic Virus

In an earlier communication[1], it was reported that the latent period after infection with virus ribonucleic acid is about 10 hr. shorter than after infection with complete tobacco mosaic virus. The simplest explanation for this effect is that the release of ribonucleic acid from the virus takes some time. But even after infection with pure ribonucleic acid, there is a latent period of about 10–20 hr. We have now studied the events during this remaining period in some detail. It seems possible that the first event after infection is a multiplication of the released ribonucleic acid and that a certain amount of it has to be formed before the synthesis of the virus protein can be initiated ; this protein will later combine with the ribonucleic acid to form the complete virus.

Infectious ribonucleic acid cannot be detected when the extraction is carried out with aqueous solutions because it is destroyed by the ribonuclease present in the tobacco leaves. To determine the free ribonucleic acid in the presence of virus nucleoprotein we used the following technique. Leaves of infected *Nicotiana tabacum* (Samsun) were homogenized in the presence of phenol and phosphate buffer. Thus the enzymes of the leaves are destroyed immediately after disruption of the cells and the infectivity of the ribonucleic acid is preserved and can be determined after removal of the phenol phase. By this extraction we obtain the total ribonucleic acid (that is, free ribonucleic acid plus virus-ribonucleic acid). In parallel experiments the amount of virus or virus-ribonucleic acid was determined by two different methods. Part of the same tissue was extracted by buffer without phenol, and the amount of complete virus was bio-assayed on *N. glutinosa* as already described[1]. Since tobacco mosaic virus produces many more local lesions than virus-ribonucleic acid, the ratio of free ribonucleic acid to virus-ribonucleic acid can be calculated only indirectly by this method. To determine directly the ribonucleic acid bound in the virus the infected leaves were homogenized with buffer as before and the solution was incubated for 1 hr. at 37° C. to inactivate the free infectious ribonucleic acid. Ribonucleic acid which is within the virus remains intact after this treatment. The protein was then extracted with phenol and the activity of the liberated virus-ribonucleic acid was measured.

Several series of experiments were carried out in the following way. Young plants of *N. tabacum* (Samsun) were infected with a solution of 10^{-6} gm. tobacco mosaic virus per ml. as previously described[1]. The plants were kept under constant illumination at 23° C. After certain intervals the primarily inoculated leaves were harvested. For each determination eight plants were used. Part of these leaves was homogenized with 0·01 *M* phosphate buffer at *p*H 7·2 and phenol. The phenol was removed with ether and the aqueous ribonucleic acid solution was used for the local-lesion test. The remaining leaves were homogenized with buffer alone. An aliquot of this latter extract was used for the determination of the complete virus. The main portion was incubated at 37° and treated with phenol afterwards for the determination of the virus-ribonucleic acid.

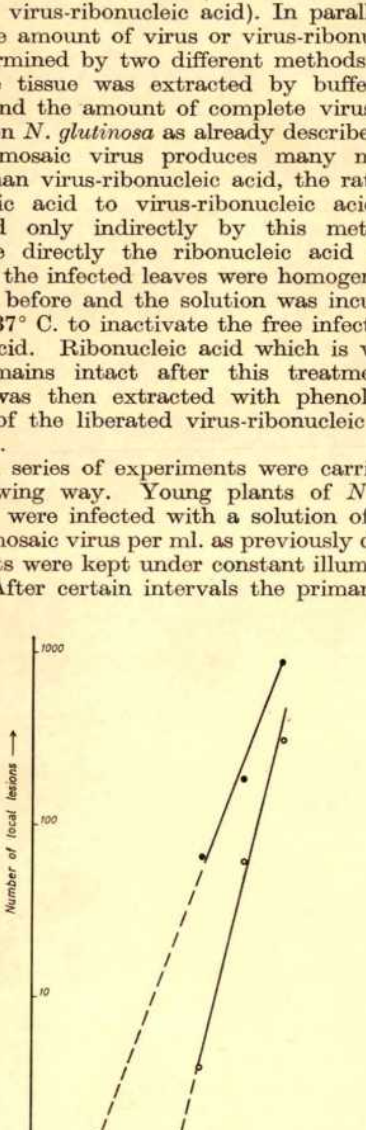

Fig. 1. Increase of total infectious ribonucleic acid, ●——●, and complete virus, ○——○, in *Nicotiana tabacum* measured by the local-lesion test on *Nicotiana glutinosa*

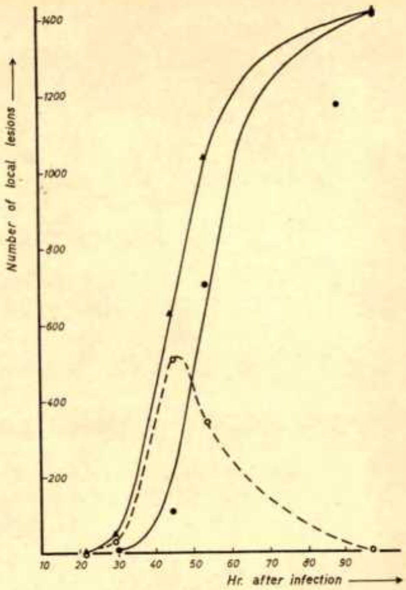

Fig. 2. Increase of total infectious ribonucleic acid, ▲——▲, virus-ribonucleic acid, ●——●, and free ribonucleic acid, ○- - -○, in *Nicotiana tabacum* after infection with tobacco mosaic virus measured by local-lesion test in *Nicotiana glutinosa*

Results of two typical experiments are illustrated in Figs. 1 and 2. In Fig. 1 the increase of total infectious ribonucleic acid and of complete virus measured by the number of local lesions is plotted on a logarithmic scale. At first the activity of the total infectious ribonucleic acid was much greater than the activity of the complete virus. 18 hr. after infection, the total ribonucleic acid produced 68 lesions and the virus only 4. As tobacco mosaic virus produces per mole about 1,000 times as many local lesions as ribonucleic acid, the amount of free ribonucleic acid is about 17,000 times that of the tobacco mosaic virus ; 22 hr. after infection the ratio was about 4,000. In Fig. 2 the numbers of local lesions produced by the total ribonucleic acid and by the virus-ribonucleic acid obtained after incubation and phenol treatment are compared. The difference between the two curves (representing the free ribonucleic acid) is also plotted. It is interesting that the amount of free ribonucleic acid reached a maximum after about 45 hr. and decreased to a small value after 100 hr.

The experiments show that, after infection, a considerable amount of infectious ribonucleic acid is produced before the synthesis of the virus protein starts. This infectious ribonucleic acid, which is not incorporated in the virus, is called free ribonucleic acid. Of course, it is not certain whether it is really free or bound to some other unknown material. From Fig. 2 it can be seen that the difference of time between the rise in free ribonucleic acid and the incorporation of ribonucleic acid in the virus is about 10 hr. For the envelopment of one molecule of ribonucleic acid more than 2,000 peptide sub-units are necessary. An estimation of the rate of production of ribonucleic acid and virus leads to the conclusion that protein is produced more rapidly than ribonucleic acid. Thus, the amount of free ribonucleic acid is reduced by combination with this protein.

In earlier experiments it was demonstrated that during the latent period complete virus is not detectable. Our results give a plausible explanation of this fact. After the entrance of the virus into the cell, the virus particles disintegrate to form ribonucleic acid and protein. The ribonucleic acid multiplies first. The synthesis of the protein starts several hours later, but is much faster. Therefore the amount of free ribonucleic acid reaches a maximum, and decreases afterwards as a consequence of combining with the protein. The latent period in the multiplication of the virus is mainly due to the fact that the release of the ribonucleic acid and its multiplication take some time before the formation of the protein and of the complete virus starts.

Further evidence of free ribonucleic acid as a precursor of tobacco mosaic virus is the inhibition of virus multiplication when ribonuclease is introduced before, or shortly after, the virus[2,3]. The presence of infectious ribonucleic acid in tobacco plants infected with tobacco mosaic virus was also deduced by Cochran[4] from chromatographical experiments.

We are grateful to the Deutsche Forschungsgemeinschaft for financial support.

A New Method for the Microbiological Oxidation of Steroids

The microbiological steroid transformations in the preparation of sex- and adrenocortical hormones opened a new field for the use of micro-organisms in organic synthesis. An interesting feature of these reactions is the ability to transform substances which are practically insoluble in water in an aqueous medium. It seems obvious that this transformation does not take place in the aqueous phase itself but on the lipoid surface of the micro-organisms. When the fermentation broth and the mycelial mass are treated separately after such transformations, the fermentation broth contains relatively more polar transformation product and less starting material, whereas considerable quantities of the initial steroids could be recovered from the mycelial mass.

Peterson and Murray[1] reported an 80–90 per cent yield of 11α-oxyprogesterone, prepared with *Rhizopus nigricans* from progesterone, and they also found 6β-11α-dioxyprogesterone and 11α-oxyallopregnanedione in the broth. Our strain of *Rhizopus nigricans* gave a 60–70 per cent yield with the dioxy-compound as a by-product. In a fermentor, using glucose, corn-steep liquor, and sodium chloride for the culture medium, and about 10^8 spores per litre for the inoculation, *R. nigricans* grows as a voluminous mucous mass. If the inoculum consists of 10^5 spores per litre it grows in pellets, that is, globules 3–4 mm. in diameter. In our experiments, 400 ml. from a culture of this type were placed in a chromatographic column of 4 cm. diameter fitted with a sintered glass plate, No. *G*–1. The apparatus is shown in Fig. 1. The fluid rises through the lower four-way joint (1) into the glass tube (2), placed alongside the column, the bent part of which reaches into the column. Air is blown through a capillary (3) and thus the broth is continuously forced from the tube into the column and saturated with air at the same time. To the fluid thus kept in constant circulation 160 mgm. of progesterone dissolved in 4 ml. of acetone were added. The speed of circulation of the broth was 250 ml./min. At 6, 8, 10, 12, 14, 16 and 18 hr. after the addition of progesterone, 250-ml. portions of the fermentation broth were drained off through the lower stopcock (4) and the same quantities of fresh broth added. The 6, 8 and 10 hr. portions contained 40 mgm. progesterone each, consequently a total of 280 mgm. of progesterone was added. The experiment was stopped after 20 hr. The broth samples were shaken with twice their volume of dichloroethane, the mycelium globules (5) retained in the column were extracted twice with 10 ml. of acetone and three times with dichloroethane, using 100 ml. of this solvent altogether. The extracts were washed with a 2 per cent solution of sodium bicarbonate, then with water, dried with sodium sulphate and, finally, investigated quantitatively by paper chromatography[2].

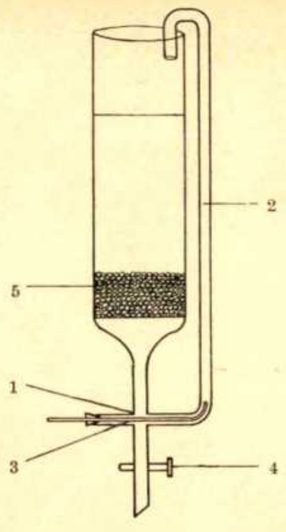

Fig. 1

Table 1

Sample taken at (hr.)	Contents of 11α-oxyprogesterone (mgm.)	Progesterone (mgm.)
6	58·8	—
8	51	—
10	35·6	—
12	33·8	—
14	30	—
16	21·8	—
18	9·7	—
20	3·7	—
From mycelium	0	38
Total	244·4	

Total recovery of steroids, 282·4 mgm.; conversion yield, 86 per cent

The results in Table 1 demonstrate the advantages of the method employed. The uncontaminated transformation product can be obtained from the fermentation broth, and the unchanged substrate recovered separately from the mycelial tissues. No loss occurs since the small quantity of untransformed progesterone can be totally recovered. The useful product is not subject to further oxidation since it is continuously extracted from the system. Tap-water can be used in place of the fermentation broth when changing the fluids ; in this case recovery becomes more simple still. The method can be used for all microbiological steroid conversions where the organism performing the transformation can be grown in pellet form and the polarity of the substrate molecule to be converted is not such as to make it soluble in the aqueous fermentation broth. Further, by this microbiological method, one of the great inconveniences of the fermentation process is obviated : it is not necessary to extract the final product from the whole broth, which may contain a number of undesirable contaminating substances.

A Rare Sperm Abnormality : 'Corkscrew-sperms' associated with Sterility in Bulls

Williams and Savage[1] introduced a semen examination method for the evaluation of the seminal micropathology in bulls, the results of which in the hands of the experienced examiner are of definite value in sterility work, especially in classifying the severity of testis degeneration and testis hypoplasia. Later investigators have used slightly different systems for classifying abnormal sperm forms, but most workers have included abnormalities of the middle piece of the sperm in their counting as rather rare forms[2–4].

In 100 normal fertile bulls which I examined in 1950, by counting 500 sperms from each case, middle piece defects were only demonstrated in 0·27 per cent of the primary sperm abnormalities. Furthermore, in a long series of semen slides from cases of sterility in bulls examined by me during the past 15 years, middle piece abnormalities were never found as the main defect.

It was therefore of great interest to receive, within a period of a few months, from different parts of the country, abnormally thin semen samples from two sterile bulls showing almost the same morphological picture : most of the sperm heads were normal, but a high percentage of the sperms had middle pieces shaped like a corkscrew (Fig. 1), an abnormality which I had previously regarded as a curiosity.

By ordinary microscopy (× 1,000) the corkscrew sperms were easily seen and counted in slides stained with eosin–nigrosin[5] (Fig. 1*c*). In simple wet preparations also the abnormality was clearly distinguishable, especially by phase-contrast (Figs. 1*a* and *b*). None of the abnormal sperms was motile and none of them remained unstained (alive-reaction) with eosin–nigrosin.

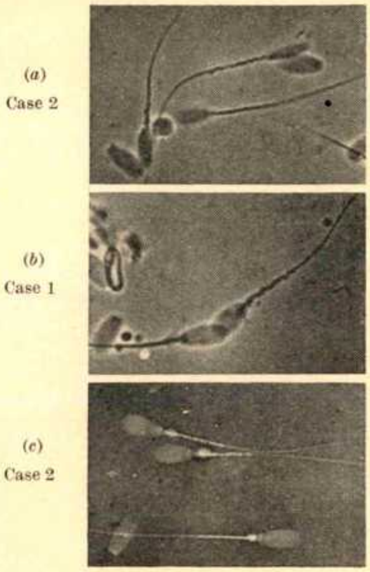

Fig. 1. Photographs showing typical corkscrew-sperms together with apparently normal sperms (× 600). (*a* and *b*) Phase-contrast exposures from wet preparations ; (*c*) a slide stained with eosin–nigrosin

Case 1. RDM bull, 5 years old. Until December 1957 the bull was used regularly at an artificial insemination centre. Semen quality and fertility : fair. Dilution rate : generally 1 + 2 only. From January 1958 semen quality was going down, motility almost nil and concentration decreasing rapidly, so the bull was taken out of use. Clinical examination, July 1958 : testis normal sized, probably with some fibrous induration.

Table 1

Date of semen examination	Motility (per cent)	Sperms/mm.^{3}	Corkscrew sp. (per cent)
Aug. 27, 1958	<1	40,000	24
Sept. 2, 1958 (I)	<1	100,000	15
Sept. 2, 1958 (II)	<1	50,000	16

Diagnosis : Testis degeneration, cause unknown.

Unfortunately this bull was sent for slaughter without further examination being made.

Case 2. RDM bull, 12 years old. Has belonged to the same artificial insemination centre for about 11 years. During the first 9 years the bull was used regularly three times weekly and always had semen of top quality and high fertility. When the bull was about 10 years old sperm concentration decreased somewhat and fertility dropped to fair. From April 1958 the semen was practically dead and of low concentration (last successful insemination March 1958). This bull is still alive.

Table 2

Date of semen examination	Motility (per cent)	Sperms/mm.^{3}	Corkscrew sp. (per cent)
Oct. 22, 1958 (I)	<1	200,000	23
Oct. 22, 1958 (II)	<1	100,000	27
Nov. 5, 1958	<1	200,000	31
Nov. 19, 1958	<1	75,000	45
Dec. 1, 1958	<1	75,000	49

Diagnosis : Testis degeneration, cause unknown.

The occurrence of characteristic corkscrew sperms with twisted middle pieces in 15–49 per cent by the differential sperm count in two sterile bulls (primarily fertile) seems to indicate the existence of a hitherto rare form of testis degeneration, where the specific blastema for the middle piece, including the so-called mitochondrial sheet, is affected.

Of these two sterile bulls it was only possible to follow one during a short period before slaughter, while semen samples from the other were examined during some months, showing that the occurrence of corkscrew-sperms increased regularly, from 23 to 49 per cent, while, as a decrease in sperm concentration indicated, degeneration of the testis tissue was in progress.

Only Bretschneider[4] (drawing 114) seems to have encountered a similar phenomenon, with a sort of macrohelix-structure in the middle pieces in 20 per cent of the sperms, but unfortunately no photographs and no information about the fertility of the bull in question are given. These results seem to indicate that investigators who are doing morphological sperm examinations for fertility in bulls should pay full attention to the condition of the middle pieces, and in future work also include corkscrew-sperms in the group of primary sperm abnormalities.

Hair as a Substrate for Non-Keratinolytic Fungi

DURING a study of the fungal succession occurring on hair decomposing in contact with soil, it has become apparent that hair, either autoclaved or sterilized with propylene oxide, can support the limited growth of many fungi which are not keratinolytic. Thus species of *Mortierella*, *Cunninghamella* and *Chaetomium*, as well as of many genera of the Fungi Imperfecti, for example, *Aspergillus*, *Gliocladium*, *Penicillium*, *Alternaria*, *Curvularia*, *Epicoccum*, *Helminthosporium*, *Phoma*, *Pyrenochaeta*, grow sparsely on the hair surface and produce spores there.

The ease with which such fructifications can be examined has led to the use of hair as a fungal substrate for class purposes while teaching mycology. Fine human hair, sterilized either by autoclaving at 15 lb. pressure for 15 min. or with propylene oxide[1], is placed on the surface of a thin layer of agar of low nutrient status contained in a Petri dish, and the agar is inoculated with the fungus to be studied. Within a few days, the mycelium has spread from the agar to colonize sparsely the hair surface, and scattered conidiophores are produced. A hair is then carefully removed with forceps and mounted on a slide in any suitable mounting fluid. The preparation, under a cover-slip, can then be readily examined under a microscope. The great advantage of the method lies in the ease with which an inexperienced worker can obtain an undisturbed preparation of conidiophores and conidia, clearly revealing the exact method of production of the latter, a detail which is assuming an increasing importance in taxonomy[2]. Although the mode of production of conidia remains typical, the poverty of hair as a substrate for the majority of fungi occasionally leads to a simplification in conidiophore morphology. Thus in the genus *Penicillium*, the penicillus is frequently of a simpler nature than the corresponding structure produced on an agar medium, so that the hair technique is not satisfactory when specific identification is attempted in such genera.

The method has also proved advantageous in promoting either the asexual reproduction of apparently sterile cultures or the production of more easily characterized structures in those cultures which produce nothing but an ill-defined mass of simple slime spores on the normal agar media. In many cases cultures of either of these types have readily produced pycnidia on the hair surface.

Discoloration of Wool Fibres by a Fungus

A COMPLAINT by a wool processer in Japan that part of a consignment of New Zealand raw fleece wool in the coarse-quality range was affected by a black discoloration which could not be removed in the ordinary wool scouring process, or by any common solvent, has been investigated and the cause of the discoloration established as being due to a fungus growing in the fibres.

In outward appearance the distal part of the staple was dark coloured and similar in appearance to wool contaminated by dust and dirt. All parts of the fleece appeared to be equally affected. On scouring or after solvent-treatment the affected staple tip remained dark. In the region of discoloration, fibres had a very low tensile strength characteristic of extreme weathering.

Microscopic examination showed the fibre to be outwardly intact. Large fungal hyphæ were obvious within the fibre and cross-sections showed a severe mechanical disruption of cortical cells within the fibre, this no doubt contributing to the loss of tensile strength. Within the fibre the hyphæ are moniliform in shape and dark in colour. At irregular intervals the hyphæ anastomose and fruiting structures are formed which finally reached the surface by breaking through overlying cortical and cuticular cells of the fibres. Minute hyaline ellipsoidal unicellular or two-celled spores are produced in these structures.

The fungus was isolated from affected wool by placing short lengths of the infected fibres on tryptone glucose extract agar ('Difco') to which 0·01 gm./ml. of 'Terramycin hydrochloride' had been added aseptically just prior to pouring the plates. The fungus, which grew out readily, was transferred to slants of the same medium, where it formed fruiting bodies profusely. The fungus is reported by the Commonwealth Mycological Institute to be a species of *Peyronellaea*, not recorded from wool but close to *Peyronellaea glomerata* (Corda) Goidanich, and has been disposed in the Commonwealth Mycological Institute herbarium as *I.M.I.* 74752.

No reports of fungus damage to unprocessed wool have been found in the literature, although several unidentified actinomycetes have been shown to be capable of bringing about a rapid disintegration of wool fibres while still on the sheep[1], and this present report indicates a further source of damage by a group of organisms that has been little studied in relation to the fleece.

Further investigations into the methods of spread of the fungus and its infection of wool are in progress and a full account will be published elsewhere.

Abnormal Development of the Basis in *Balanus amphitrite* var. *stutsburi* Darwin

The deformation of barnacle shells by growth on unfavourable substrates is now well known[1,2]. The distinctive scalloped form of basis produced on toxic anti-fouling paints has been illustrated by these and other authors. The same deformity occurs when settlement takes place on a toxic metal surface, for example, the copper sheathing of a wooden hull.

Recent examination of some specimens of *Balanus amphitrite* var. *stutsburi* Darwin from "West Africa" in the City Museum, Bristol, dating from the mid-nineteenth century and conceivably belonging originally to Samuel Stutchbury, showed that four of the five specimens handled have this deformed basis (Fig. 1). The fifth is regular in outline except where distorted by two small encrusting oyster shells. Spectrographic examination of green material in the crevices of the contorted bases indicated a high percentage of copper. No copper was associated with the other smooth-shelled specimen. Nor was any found in the glue used to secure the specimens to the display 'tablet'. It is practically certain therefore that the deformed specimens are derived from the bottom of a copper-sheathed ship on which they arrived in Great Britain, presumably from West Africa, the home of this variety.

In the Darwin cirripede material in the British Museum (Natural History) there are mounted on a tablet, among other named varieties, eight numbered specimens assigned to *B. a. stutsburi* in a manuscript list in Darwin's hand. Of these, five are distorted specimens, one (No. 18 on the tablet) possibly the original of Darwin's illustration of the variety (Pl. V, Fig. 2*d*)[3]. Thus Darwin illustrated a deformed specimen only while also having normal material before him. This is still the only illustration of the complete shell of *B. a. stutsburi*.

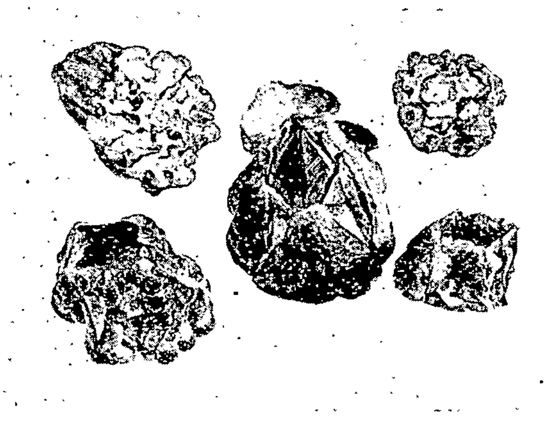

Fig. 1. *B. amphitrite stutsburi* Darwin. Four deformed specimens from a copper substrate and one normal smooth-walled specimen. (Bristol City Museum Collection)

Current examination of a large collection of new material of the variety from West Africa has shown that the rugged or deformed type figured by Darwin does not occur on natural and non-toxic substrates, for example, shells, stones, wood, concrete and iron, and that *stutsburi* is normally a smooth variety of *B. amphitrite* in its natural habitat.

The form and variability of this and some other varieties of *B. amphitrite* will be discussed at greater length in subsequent papers to be published, in collaboration, elsewhere.

I am indebted to the Director, City Museum, Bristol, for the loan of the specimens figured here, to my colleague, Mr. L. G. Young, for the spectrographic examinations of the copper-containing inclusions from the bases, and to the Director, British Museum (Natural History), for permission to examine the Darwin and other material in that Museum.

A Quantitative Serum–Agar Technique

While investigating the changes which occur in plant cytoplasmic proteins during growth and differentiation, using the Ouchterlony serum – agar plate technique[1], the need arose for a quantitative method of estimating the protein constituents. Although there are several methods available[2–7], none of them is easily applicable to a multi-antigenic system, and in addition the concentrations of the proteins can only be estimated separately, even under favourable conditions, at ±10 per cent and more usually ±50 per cent.

With the method described here it has been possible, with the system studied, to estimate the relative protein concentration within ±4 per cent, and it is probable that the technique could be developed to limits of ±2 per cent. The sensitivity of the technique is dependent on at least three factors: standardization of procedure; the titre of the individual protein or proteins; and the accuracy with which one can pipette the small volumes of liquid which have to be used when the antiserum, and sometimes the antigen solution, is in short supply.

The method consists of titrating antigen on to antibody and following the titration on a modified Ouchterlony plate. Two end-points are obtained (Fig. 1): (*a*) where free antibody is just detectable; (*b*) where free antigen is just detectable.

The technique is as follows: into a series of small tubes is pipetted a standard volume of antiserum (0·1 ml. of monospecific siderophilin antiserum was used in these experiments). To each of these is added the same volume of antigen in a series of different concentrations (normal human serum diluted

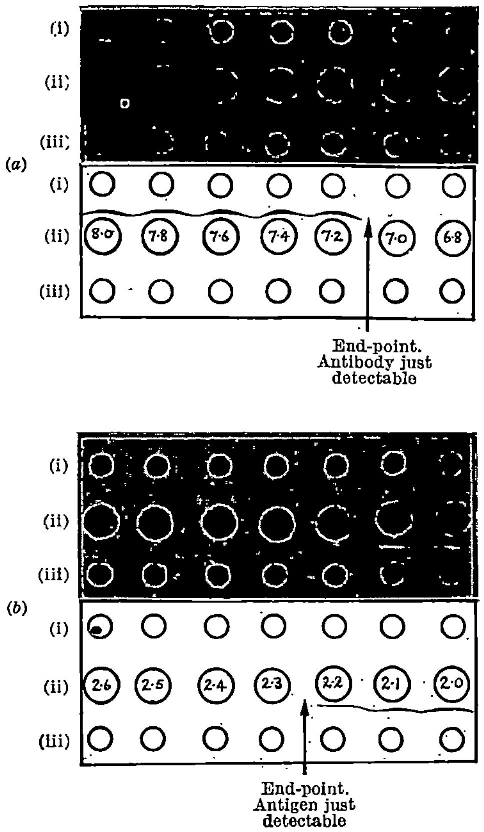

Fig. 1. The determination of the two end- or extinction-points for siderophilin: *a*, where free antibody is just detectable; *b*, where free antigen is detectable. (i) Total human serum diluted × 8; (ii) monospecific siderophilin antiserum absorbed with a range of concentrations of total serum; the figures indicate the dilution of the antigen; (iii) the above antiserum diluted × 4

with physiological saline). The antibody and antigen are allowed to react for 2 hr. at 37° C. and then agar plates are set up as shown in Fig. 1 (0·6 per cent w/v New Zealand agar in veronal buffer, pH 8·6 (sodium diethylbarbiturate 0·1 M; diethylbarbituric acid 0·02 M)) using equal volumes of absorbed antiserum in each well and similarly for unabsorbed antiserum and antigen. The plate is incubated at 37° C. for 20 hr. and the end-point determined visually. (37° C. was used for both the initial reactions and for the end-point detection test; in certain circumstances, especially with weak antiserum, periods at 0° C. might be preferable.)

This experiment describes the determination of the two end-points for a standard antigen solution when used in conjunction with a particular antiserum. To estimate the concentration of the antigen in an unknown solution it would be necessary to determine only one of the two end-points (preferably the sharper, usually, as in this instance, the one where antigen is just detectable) and to express it in arbitrary units based on the standard. In the rare event of a pure antigen being available the end-point could be expressed as mgm. protein.

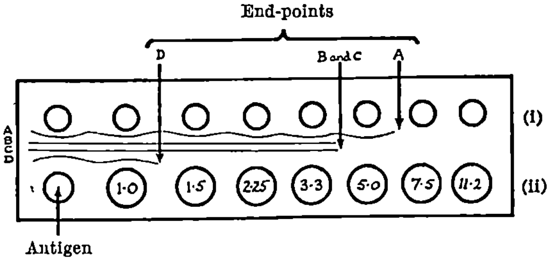

Fig. 2. Hypothetical example of the determination of the end-points (that is, where free antigen is just detectable) of a multiple protein system: (i) antiserum; (ii) antiserum absorbed with a range of concentrations of antigen. The figures indicate the dilution of the antigen

On theoretical grounds the end-point where antigen is just detectable is likely to be the more sensitive, because it is favoured by the shape of the precipitation curve, which is usually not symmetrical about the equivalence point, and because a small amount of antigen is more easily detectable than a small amount of antibody. Using this end-point for a multiple protein system several lines can be identified by setting up a plate as shown in Fig. 2, which shows a hypothetical example of the simultaneous estimation of all four antigens.

I wish to thank Prof. J. R. Squire for his encouragement and advice and Dr. P. G. H. Gell for his constructive criticisms.

The work was carried out under a grant from the Nuffield Foundation.

Photographic Recording of Agar Diffusion Plates

A NUMBER of requests have been received at this Establishment asking for details of the method and materials used for the photographic recording of agar diffusion plates[1-4]. It may be of help to those using the Ouchterlony[5] and Mansi[6] techniques if the successful system devised and regularly in use here is made more widely known.

It was found that the greatest contrast, both visual and photographic, between the lines of precipitation and the background, is obtained when the beam of transmitted light is as nearly as possible normal to the agar surface, without the source itself being visible to the eye or the lens. The apparatus shown in Fig. 1 is one of the most compact and stable arrangements which will fulfil this condition. The bright aluminium sheet serves to reflect excess light and heat from the 500-watt spotlights, and has a circular aperture a little larger than that of the blackened dish support, which is separated from it by washers as spacers to prevent heat transfer. Standard 9-cm. Petri dishes are generally used, but a series of metal annuli, blackened on top and bright underneath, having 9-cm. outside diameters and three registering pegs set equilaterally around the inside diameters, support smaller dishes centrally over the aperture, and at the same time exclude excess light. Using a 13·5-cm. Tessar lens, 9-cm. dishes are photographed at a small degree of direct enlargement (to

11 cm.) on quarter-plate cut film. A stop of $f/8$ gives sufficient depth of field to bring the whole thickness of agar into focus. With high-contrast film (Ilford 'Ortholine', *G*5.51) and an exposure time of 1/50 of a second, 5 min. development in a standard phenidone-quinone developer (Ilford *I.D.* 62) allows adequate contrast, without blocking up the finer and fainter lines.

As the plane of light falling on the Petri dish tends to be diametral, separation of a close-running 'family' of lines, particularly where strong and faint ones are adjacent, is greatest when their direction is set parallel to that plane, as otherwise the scatter of light from the heavy lines may overshadow the finer ones. Lines of a circular precipitation zone around a cup are well differentiated even when at right angles to the light plane ; this is not always the case with fully annular lighting, such as that from a Quebec colony counter, in which the rays are much nearer parallel to the agar surface.

Since this method of lighting was designed to accentuate the faintest lines to the greatest possible degree against a dark background, it follows that dust and fibres on the agar, and scratches on the bottom of the Petri dish, are also brought into prominence. Debris on the surface can be kept to a minimum by care taken when the dish is opened for inspection of the lines. Scratches and irregularities on the bottom of the Petri dish can be removed effectively, for the purpose of photography, by temporarily 'cementing' the dish to a scratch-free and flawless glass disk of suitable size with glycerine, avoiding the inclusion of air-bubbles.

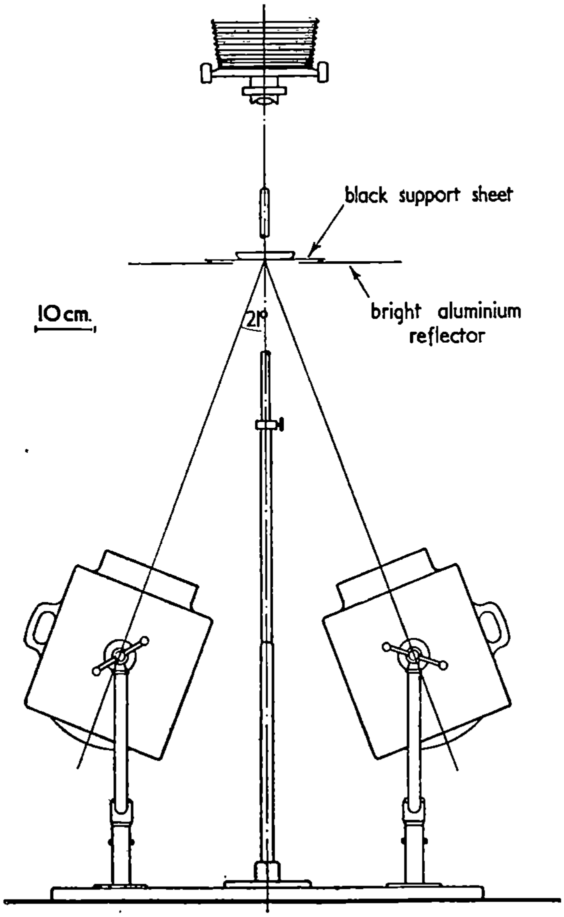

Fig. 1. Diagram of apparatus

Fig. 2. Routine record of a *Pasteurella pestis* antigen–antibody system

In order that the equipment may be used for routine recording by staff who are not trained photographers, the number of variables has been kept to the absolute minimum. The camera, which is also used in conjunction with other equipment, is fixed to the wall, and has register marks on the adjustable stays. The spotlights and dish support, in one unit on a baseboard, are centred under the lens by means of spacing-rods to the wall. Negative processing is standardized by time and temperature. The greater degree of direct enlargement of smaller Petri dishes is compensated for in the normal way by an increase in exposure time, but is not often needed. There is sufficient latitude, even with the high-contrast emulsion used, normally to cover the amount of variability inherent in the diffusion plates themselves and good-quality negatives are obtained with the standard exposure time. Very little practice is needed to learn when slight adjustments will be required.

Two years experience has shown that the faintest of lines can be recorded with ease, and with an accuracy and saving of time much greater than is obtainable when the lines are recorded by drawing.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 4

Faraday Society (at the Imperial College of Science and Technology, South Kensington, London, S.W.7), at 4.30 p.m.—Dr. Robert Gomer (University of Chicago): "Surface Diffusion" (Bourke Lecture).*

London School of Economics and Political Science (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. M. J. Wise: "Industrial Location—a Geographical Approach"* (Inaugural Lecture).

British Society for the History of Science (in the Council Room of the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. Churchill Eisenhart: "The Background and Evolution of the Methods of Least Squares".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. D. J. Ayres: "Grouting and the Civil Engineer".

University of London (in the Large Chemistry Theatre, Royal College of Science, London, S.W.7), at 5.30 p.m.—Prof. W. Lochte-Holtgreven: "Magnetic Fields in Rotating Plasma".* (Last of three Special University Lectures on "Spectroscopic and Magnetic Studies of Thermally Excited Plasmas".)

Royal Society of Arts (at John Adam Street, Adelphi, London. W.C.2), at 6 p.m.—Mr. J. R. Whinfield: "Research in Man-made Fibres". (Last of three Cantor Lectures.)

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Mr. E. L. Streatfield: "The Conveyor Concept of Water in Industry".

Tuesday, May 5

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. A. L. Hodgkin, F.R.S.: "Propagation of Electrical Signals along Nerve Fibres".

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. V. B. Mountcastle (Johns Hopkins University): "The Central Nervous Mechanisms in Somatic Sensation".* (First of two Special University Lectures in Human Anatomy and Morphology. Further lecture on May 7.)

University of London (at the Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Academician I. A. Kairov: "Education of Students in the Spirit of Patriotism, Peace and Friendship amongst the Nations".* (Further lecture on May 8.)

British Council, and the Joint Committee on Structural Concrete (at Friends' House, Euston Road, London, N.W.1), at 6 p.m.—Mr. Felix Candela: "Ten Years Building Thin Shell Structures".

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Prof. F. E. Zeuner: "The Origins of Domestication—a Synthesis".* (First of six lectures on "Animals in Archæology". Further lectures on May 12, 19, 26, June 2 and 9.)

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. I. M. Ross, Mr. C. P. Lea-Wilson, Mr. A. J. Monk and Mr. A. F. H. Thomson: "An Experimental Diode Parametric Amplifier and Its Properties".

Plastics Institute, London and District Section (at the Wellcome Building, 183–193 Euston Road, London, N.W.1), at 6.30 p.m.—Annual General Meeting. Mr. C. Shaw: "Precision Cast Moulds and Tools for the Plastics Industry".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—27th Annual General Meeting, followed by Mr. C. E. Hollis: "The Pursuit of Polymers" (Chairman's Address).

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. R. H. Scott: "The Potential Use of Aircraft for Agricultural Purposes (with particular reference to New Zealand)".

Wednesday, May 6

Society of Dairy Technology (at the Federation of British Industries, 21 Tothill Street, London, S.W.1), at 10.30 a.m.—Meeting on "Some International Aspects of the Dairy Industry".

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Symposium on "Submarine Exploration for Oil" presented by Members of B.P. Exploration Co., Ltd.

Society of Instrument Technology (at Manson House, Portland Place, London, W.1), at 5.30 p.m.—Annual General Meeting. 6.30 p.m.—Presidential Address.

University College, Department of Hebrew (in the Gustave Tuck Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Theodor H. Gaster (Dropsie College for Hebrew and Cognate Learning): "New Light on the Dead Sea Scrolls".* (Further lecture on May 7.)

University of London (in the Small Physics Lecture Theatre, Royal College of Science, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Prof. M. Biernacki (Marie Curie-Sklodowska University, Lublin): "Sur les Extréma des Combinaisons des Fonctions, Sous-Harmoniques et de leur Généralisations".*

University of London (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. D. J. van Lennep (Utrecht): "Recent Studies on the Personality of the Proficient Research Worker". (Further lecture on May 7.)

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—Annual General Meeting, followed by Films.

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Annual General Meeting, followed by Dr. S. G. Clarke: "Corrosion as a Design Problem" (Chairman's Address).

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "The Design of Experiments in Analytical Chemistry". Dr. E. C. Wood: "The Fundamental Principles of Modern Experiment Design"; Mr. W. C. Wake: "Statistics in Standardizing Chemical Methods".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting—"As Others See Us". Chairman: Prof. A. V. Hill, F.R.S. Speakers: Dr. C. Kemal Reheem: "Some Views from Pakistan on British Science"; Dr. Thomas H. Osgood: "The American View"; Mr. A. C. Copisarow: "Impressions from Some West European Countries".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. David R. Newith: "Black Axolotl, and White".

Wednesday, May 6—Thursday, May 7

Iron and Steel Institute (at Church House, Westminster, London, S.W.1), at 10 a.m. daily—Annual General Meeting.

Thursday, May 7

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. W. T. J. Morgan, F.R.S.: "A Contribution to Human Biochemical Genetics: The Chemical Basis of Blood Group Specificity" (Croonian Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. K. Mather, F.R.S., and Dr. J. A. Roper: "Cytoplasmic Inheritance"; Mr. W. T. Stearn: "Baron von Humboldt (1769–1859)".

London School of Economics and Political Science (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Mr. T. H. Marshall: "International Comprehension in and through Social Science"* (Hobhouse Memorial Lecture).

Institute of Refrigeration (joint meeting with the Low Temperature Group of the Physical Society, at the Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. D. Hurden: "Cryogenic Liquids for Rocket Engines".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. M. Waldram: "Lighting and Architecture".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. Phyllis Kaberry: "Nsaw Political Conceptions".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. François Jacob (Institut Pasteur, Paris): "Viruses in Relationships with some Genetic Elements of the Cell".*

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Some Problems Encountered in Anodic Polarography".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, May 8

Aslib (in consultation with the British Association of Industrial Editors, the North-Western Polytechnic, and the Presentation of Technical Information Group (at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C.2), from 10.30 a.m. to 5 p.m.—Conference on "The Presentation and Interpretation of Technical Information".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. H. H. Plaskett: "Solar Rotation and Photospheric Circulation"; Dr. M. J. Seaton: "The Calculation of Recombination Spectra".

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Microwave Radiation Hazards", opened by Dr. D. H. Shinn and Dr. N. L. Lloyd.

University of London (at the Royal Holloway College, Englefield Green, Surrey), at 8.15 p.m.—Sir Edward Salisbury: "The Royal Botanic Gardens, Kew, 1759–1959".

Friday, May 8—Saturday, May 9

British Society for Immunology (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1)—Spring Meeting.

Friday, May 8, at 11 a.m.—Symposium on "Delayed Hypersensitivity". Chairman: Prof. G. Payling.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in the Department of Biochemistry—The Secretary, The University, Edinburgh (May 9).

Senior Lecturer in the Department of Biochemistry—The Secretary, The University, Edinburgh (May 9).

Junior Biochemist (with an honours degree)—The Secretary, Institute of Animal Physiology, Agricultural Research Council, Babraham, Cambridge (May 15).

Junior Lecturer/Lecturer in Physiology—The Secretary, The London Hospital Medical College (University of London), Turner Street, London, E.1 (May 15).

Research Assistant (Physical Chemist), for work with organometallic compounds—The Secretary, The University, Exeter (May 15).

Foresters (2) (with a Diploma or a Certificate of a recognized foresters' training school and preferably aged between 20 and 25) on the Staff of the Southern Rhodesia Forestry Commission—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (May 16).

Lecturer or Assistant Lecturer (interested in the mechanisms of reactions) in the Department of Organic Chemistry—The Registrar, The University, Liverpool (May 16).

Map Curator (preferably geography graduate with an interest in maps and bibliographic work) in the Department of Geography—The Registrar, The University Leeds 2 (May 16).

Lecturer (with qualifications in physical science or mathematics) in the Department of Education—The Registrar, University College of Wales, Aberystwyth (May 18).

Assistant Lecturer in Metallurgy—The Registrar, The University, Nottingham (May 23).

Assistant Lecturer (with a good honours degree in chemistry or agricultural chemistry) in Agricultural Chemistry—The Registrar, The University, Leeds 2 (May 23).

Research Assistant (with a good honours degree in botany or biochemistry or chemistry) in the Department of Botany, to assist in research on the mechanism of photosynthesis—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 23).

Assistant Lecturer (with an honours degree in agriculture, animal physiology or animal nutrition, or a pass degree in agriculture with a suitable postgraduate diploma, or equivalent qualifications) in Agriculture (Animal Husbandry)—The Registrar (Room 22, O.R.B.), The University, Reading (May 30).

Assistant Lecturers (honours graduates) in Physics and Zoology—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (May 30).

Esso Research Student (with, or expecting to hold, a good university degree with chemistry as the principal subject) in Chemistry—The Professor of Chemistry, The University, Southampton (May 30).

Lecturers and Assistants in Experimental Physics, Theoretical Physics, and Electronics, in the Natural Philosophy Department—The Secretary, The University, Aberdeen (June 1).

Reader in Pharmacology at Middlesex Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 1).

Chair of Biology as applied to Medicine tenable at the Middlesex Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 2).

Lecturer/Senior Lecturer (preferably interested and with research experience either in Western industrial societies or in Africa) in Anthropology, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 6).

Research Fellows (2) in the Department of Anthropology and Sociology, Research School of Pacific Studies, Australian National University, to carry out and assist in the supervision of research in social anthropology and sociology amongst primitive and advanced peoples in Australia and neighbouring parts of the world—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 15).

Assistant Lecturers (2) in Zoology—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey.

Biochemist (with an honours degree in chemistry or biochemistry, and preferably research experience) in the Chemistry Department, to carry out research on trace elements in relation to diseases of farm animals—The Secretary, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh 9.

Chair of Applied Mathematics; Associate Professor; and an Assistant Professor in the Department of Mathematics—Prof. H. H. Ferns, Department of Mathematics, University of Saskatchewan, Saskatoon, Sask., Canada.

Demonstrator in Pharmaceutics, and a Demonstrator in Pharmaceutical Chemistry—The Registrar, The University, Nottingham.

Master to teach Physics to "A" or preferably "S" level—The Headmaster, Westminster School, 17 Dean's Yard, London, S.W.1.

Research Assistant (with a degree or equivalent qualification in chemistry), for work on physico-chemical problems at high temperatures—Dr. J. W. Tomlinson, Royal School of Mines, Prince Consort Road, London, S.W.7.

Research Engineers (2) (with at least an honours degree in mechanical engineering, or in some other specialization covering fluid mechanics) in the Department of Aircraft Propulsion, for theoretical and experimental work on the fluid mechanics of gas flow in solid rocket motors—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

High performance at Low wavelengths

The absorption spectrum of maleic acid reproduced here emphasises the excellent performance of the SP.500 spectrophotometer at low wavelengths. The second graph shows the Beer-Lambert relationship at 210mμ, and illustrates the virtual freedom from stray light at this wavelength.

With the new fused silica prism, the SP.500 Spectrophotometer reaches still further into the ultraviolet—down to 186mμ, the limit set by the absorption bands of atmospheric oxygen. The advantages of this are two-fold: a new region, hitherto accessible only to specially prepared instruments is made available for every user, and the performance of the instrument, over the whole of the important 200mμ—240mμ region, reaches a new high level. The standard test specification for the SP.500 now stipulates not more than 0.2% stray light at 200mμ—a clear indication of the instrument's quality.

LIBRARY SERVICES IN BRITAIN

IN its report[*] on "University Development, 1952–1957", the University Grants Committee pointed out that much university expenditure for research is expenditure on libraries, but although it is possibly true that libraries are relatively more important to the arts and related subjects than to the sciences—it has been estimated that library expenditure per arts student is double that on other students—the importance of efficient and adequate library service in science and technology is not easily over-stressed. The University Grants Committee did not discuss library expenditure exclusively in relation to research in the humanities and the social sciences; but in this report, although it recognized the constantly increasing pressure on university libraries, it did not emphasize the importance of the library itself as a factor in university education in general. Library expenditure increased by 64 per cent between 1951–52 and 1956–57, but is still only 3·9 per cent of university expenditure compared with 3·8 per cent in 1951–52, whereas full-time students have increased from 83,458 to 89,866 and academic staffs from 8,952 to 10,485; by 1961–62 the number of students is now expected to rise to 110,000 or more. Readers' places in university libraries increased by 17 per cent between 1953–54 and 1956–57, from 17,895 to 20,938; but the increase is unevenly spread, and in some universities the position is getting worse. Moreover, the 37 per cent increase in the cost of books, periodicals and bindings between 1951–52 and 1955–56 has reduced the real increase in library expenditure to something less than 10 per cent.

Although the University Grants Committee reports that capital works to cost about £1·75 million have been started in seven universities in Britain, there is no note of real urgency in its report. According to F. E. Hirsch, the Association of College and Research Libraries now recommends that the library should receive 5–7 per cent of the total educational budget of an institute. At the Home Universities Conference last December, Prof. R. J. Pumphrey advocated doubling the library allocation and instituting a three-year plan with the object of guaranteeing to every undergraduate access at very short notice to any book he is likely to want and a place in which to read it as one means of meeting the pressure which the forthcoming expansion is likely to put upon the universities. It may be doubted whether doubling the present expenditure of £1,620,978 is anything like enough to achieve this object, and Prof. Pumphrey gave no indication of the capital expenditure that would be involved. To provide libraries of 40,000 volumes for every 600 students, with a further 10,000 for every 200 students up to, say, 300,000 volumes, as suggested by the Association of College and Research Libraries, is a major task demanding financial resources which neither the University Grants Committee nor the Ministry of Education or local authorities appear at present to be contemplating. Indeed, the expansion of university libraries, within the limits of any foreseeable resources that are likely to be made available, may need planning with some regard to the requirements of the colleges of technology and the technical colleges, if only from the point of view of the very close co-operation demanded by the Association of College and Research Libraries Committee on Standards. All are affected, too, by the presence of students coming from homes where there is no tradition of books but rather Ruskin's "abyss of penury", and who have not learned the value of possessing and cherishing even a few well-chosen books, and are unprepared to make the sacrifice that such purchase may entail.

In practice, it is probably only within the framework of an efficient and reasonable regional public library system that the needs of even the university student are likely to be met from the resources which the universities will be able to devote to library services within the next decade. These services, as already indicated, have to meet the needs of research workers, quite apart from the invaluable contribution which the universities themselves have long made to the national lending library system in Britain. The universities must thus be vitally interested in any proposals for the development of a national reference library or a national lending library for science and technology, just as the scope and content of any such libraries should be planned with some regard to regional needs and resources if duplication and waste of effort and resources are to be avoided.

It is in accordance with this that Miss H. Mews, of the University of the Witwatersrand, in a paper at the International Conference on Scientific Information last November, argued that it is a first responsibility of any central government to set up a central scientific and technical library and a national scientific and technical information service, either as an independent entity or attached to some existing institution. This has already been recognized as a primary need by the United Nations Educational, Scientific and Cultural Organization, which assisted, for example, the organization of the scientific documentation centre, Insdoc, in India. In the Union of South Africa, the Library and Information Division of the Council for Scientific and Industrial Research was from the start planned on broader lines than as a library service to the Council's laboratories only, while the Federation of Central Africa is at present considering grafting a similar service on to the library of the University College of Rhodesia or one of the existing scientific research institutes.

To a certain extent, the Department of Scientific and Industrial Research, which has been made responsible for the new National Lending Library for Science and Technology, now being planned at Thorp Arch, Boston Spa, Yorks, has, since a recommendation to that effect was endorsed by the Advisory Council on Scientific Policy some five years ago, been developing its Information Division to help inquirers over the whole field of science, apart from the military sphere. In an address on the work of the Department which he delivered to the Society of Chemical Industry at Exeter last year, Sir Harry Melville laid some stress on this function of the Department which, he said, it is proposed to extend further. In view of the success of the Department's regional offices in Edinburgh and in Wales, it was thought desirable to extend the facility over Great Britain; for although the staffs in these offices could not be experts on everything, they could provide the links whereby information could be obtained very quickly. Dr. W. L. Francis stated on September 24 that further centres already exist at Manchester, Birmingham and Newcastle upon Tyne, and others are being planned where possible in co-operation with other libraries, universities, technical colleges, chambers of commerce, etc.

There would appear to be some danger here of overlapping with the work of the Association of Special Libraries and Information Bureaux, which for more than thirty years has been functioning effectively in precisely this field; but apart from this, the success of the development will depend largely on the calibre of the regional officers. Sir Harry Melville's address, however, added little to the very meagre accounts of the work of the Intelligence Division of the Department which have hitherto appeared in the Department's annual reports; some comprehensive survey of its activities and its resources for that work appears to be overdue, particularly in view of concern currently entertained as to the ability of the Council of Scientific and Industrial Research to secure adequate resources for its work as a whole. That the position is, however, improving is indicated by a written answer in the House of Commons on March 25, when Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, stated that provision has been made in the five-year plan for 1959–64 of the Department of Scientific and Industrial Research for the National Lending Library for Science and Technology to be fully operational in 1962. It is anticipated, he said, that some buildings of the former Royal Ordnance Factory, Thorp Arch, which are being adapted for use by the library, will be ready for occupation by March 1961. When the library is fully operational, it is estimated that the annual cost will be £280,000, and the estimated cost of adapting and equipping the buildings for the library is £250,000.

It is now clear that the new Lending Library is to be independent of the Science Museum Library, although it will take over some of the literature held by the latter, which in future will concentrate on meeting the growing needs of the Imperial College of Science and Technology, London. Apart from the additional cost to the new library involved in this decision, it does not appear that attention has been given to the possibilities of savings both in the purchase of stock and in storage which would follow from the planning of a lending library in some relation to a reference library. For a library which it is intended should function primarily for postal loans, there may be no inherent need to stock its holdings of periodicals other than as microcards, at least if the original periodicals are readily obtainable from the reference collection for photocopying. It appears, moreover, from the location now announced, that the idea that the new lending library should also serve industrial areas of the north of England and the Midlands as a scientific reference library has been abandoned. Dr. D. J. Urquhardt expressed the opinion at Washington that perhaps 75 per cent of the current serials in the Science Library are so little used that one loan copy in the United Kingdom would meet the needs of all users. His statement that about 1,250 serials are sufficient to meet 80 per cent of the demand, if confirmed, has a vital bearing on the economics of regional development and the inter-library lending and stocking that are involved.

There is yet another important aspect to which neither Sir Harry Melville nor the Advisory Council on Scientific Policy refers, and that is the relation of these schemes to the British Museum Library. According to the last report of the Advisory Council on Scientific Policy, the idea of a Science Centre has now been definitely abandoned; but it should be remembered that part of that original scheme involved making the British Museum Library the repository for literature more than fifty years old. No statement has yet been made as to the scope of the new Science Reference Library, but Dr. Urquhardt has indicated that the new Lending Library will only be comprehensive from 1950 onwards. There is a possible gap here to be considered if the national library service is to be as vital and positive as Mr. F. C. Francis recommended in his presidential address to the annual conference of the Association of Special Libraries and Information Bureaux at Nottingham last September.

Mr. Francis said he hopes that in the next four years it will be possible to lay the foundations of a new library service which will give the British Museum the place in the modern world which it occupied at the end of the nineteenth and the beginning of this century. Much that he said in this address is highly pertinent to the development of national library services primarily intended to serve science and technology. He recognized, for example, the inevitability of some decentralization, but he was forthright as to the danger of being conservative and parsimonious in our thinking about libraries. That is what is most likely to prevent their full and aggressive use, and depreciate a real national asset. Mr. Francis believes that the staff of the British Museum Library are able to play a full part in co-ordinating library activities, provided there is an appropriate breakdown of services and sufficient awareness of what was being done in other libraries. He made the pertinent point that special librarians owe it to their clients to be familiar with the resources of the great collections, and ready to take the trouble to find the relevant material.

Reiterating the importance both of adequate financial resources and of seeing that money is not wasted, Mr. Francis remarked again that, with the present growth of literature and the present demands made on libraries, no library can look upon itself as being self-sufficient. It is in this context that it is essential to keep to the minimum the number of institutions receiving in full, for example, government publications, with the considerable cataloguing and storage problems involved. Again, the National Library is the only library with an obligation to maintain and preserve its collections, and this responsibility would be difficult or impossible to distribute. Likewise, it is often the only institution in a country which can provide detailed information on the thousand and one subjects for which no specialized library exists.

The Intelligence Division of the Department of Scientific and Industrial Research thus must take full cognizance of the scope of the British Museum Library if it is to perform efficiently the functions now entrusted to it; and that will be even more the case as its responsibilities for providing scientific advice for our embassies through scientific attachés increase. Sir Harry Melville and Dr. W. L. Francis referred specifically to this function, and the importance of the scientific attaché was also emphasized by Miss Mews, who referred to the value of the two-way flow of information and co-operation which is promoted by the system of scientific attachés and scientific liaison officers. Miss Mews mentioned particularly its bearing on the co-operation of professional and scientific societies, and the potentialities of their co-operation in a national library service appear to have been ignored almost completely in the official approach to the new schemes.

The original Science Centre scheme was designed to facilitate the co-operation of such bodies, with full recognition that their participation offered substantial advantages in economy, both of storage and holdings and in operating costs. It is unlikely in view of the decisions which some of the scientific societies have already been forced to take in regard to library and other accommodation that any Government scheme could to-day obtain the full advantages of co-operation that were possible ten years or more ago; none the less, even informal co-operation could offer very real benefits. This was fully realized by President Eisenhower's Science Advisory Committee, and when that Committee's Panel on Scientific Information reported last December, stress was laid on the value of the contribution to the dissemination of scientific information generally made by scientists and technologists in addition to their regular scientific or technical work. Accordingly, the scheme proposed by the Panel is intended to enable the National Science Foundation to take full advantage of all such initiative, whether informally or formally, and to create no more than the minimum of formal organization. What that minimum is cannot be determined either for the United Kingdom or for the United States without a clear view of the whole field and the potential contribution which a wide range of institutions and professional bodies could make—and this appears to be notably lacking in Britain. Moreover, the responsibilities of the National Science Foundation in regard to science information, which, besides research, includes the support of scientific publications, put it in a much stronger position to influence development and provide missing services than any existing institution in Britain could yet hope to do.

What is most discouraging is the absence of any realization at high level of the importance of an adequate national library service or appreciation of the basis on which it must be built. The Committee appointed by the Minister of Education in September 1957 under the chairmanship of Sir Sydney Roberts was concerned with the structure of the public library service in England and Wales and was charged with advising what changes, if any, should be made in administrative arrangements, having regard to the relation of public libraries to other libraries. It might have been expected, therefore, that the Committee would have given some attention to these broader issues, particularly in view of the place which some of the commercial and technical libraries at, for example, Manchester, Sheffield, Liverpool, Leeds and elsewhere have already taken as regional centres. This development, however, which was so well described by Mr. J. P. Lamb four years ago in his book, "Commercial and Technical Libraries", is virtually ignored in the Committee's report*, as are also the earlier report of the Library Association on the post-war development of the university and research libraries of Great Britain, the Association's proposals for the post-war re-organization and development of the public library service and the McColvin report on which the proposals were based. The Committee recognizes, indeed, that co-operation between libraries is essential, and that existing arrangements embrace all public libraries in the country, as well as many university libraries and those of learned societies, scientific and professional organizations and industrial concerns. It is convinced that the regional library systems must be put on a firmer basis and that both the regional bureaux and the National Central Library should be provided with sufficient financial resources.

Nevertheless, it rejects the suggestion that the regional systems and the National Central Library should form integral parts of one national system, the cost of which would be met jointly by the central Government and by the local authorities and other sources, the contributions to be assessed by a new national committee on library co-operation. Instead, it would place the responsibility for providing a satisfactory system of library co-operation on the existing eight regional library bureaux, financed by compulsory payments from each library authority. Virtually, the sole positive contribution to more effective library co-operation proposed by the Committee is the recommendation that under a new Public Libraries Act all library authorities should be given specific powers to combine or co-operate with each other and to co-operate with education and other authorities.

---

* Ministry of Education. The Structure of the Public Library Service in England and Wales: Report of the Committee appointed by the Minister of Education in September 1957. Pp. iv+57. (Cmnd. 660.) (London: H.M. Stationery Office, 1959.) 3*s*. 6*d*. net.

This would indeed remove existing legal obstacles, and the responsibility for seeing that inter-library co-operation is effective would rest ultimately with the Minister of Education, who should, in the Committee's view, exercise a general oversight of the public library service. This is in keeping with the educational functions of the public library service, but is not enough. The real problems in establishing an adequate national library service which will meet scientific and technical needs, among others, have not been faced ; and the extent to which it is a factor in industrial and scientific efficiency and not merely in education is not understood. The contribution which the commercial or technical library of a large local authority could make in developing an economic service is ignored, as are the financial implications which arise when such a body is asked to meet national needs from local resources. If the nation's growing needs for scientific and technical information, educationally or in research, in industry and in commerce, are to be met at any reasonable and practicable cost, full and effective account must be taken of all existing resources, and the means provided for efficient co-operation without making demands liable to impair the efficient discharge of any institution's primary responsibilities. Further, we must proceed boldly and imaginatively to fill lacunæ in the existing structure from national resources, making full use of all appropriate advances in the handling and processing of scientific and technical or other information.

MORE PROTEIN CHEMISTRY

Advances in Protein Chemistry, Vol. 12

Edited by C. B. Anfinsen, Jr., M. L. Anson, Kenneth Bailey and John T. Edsall. Pp. x+687. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 14 dollars.

THIS addition to the well-known series on "Advances" contains seven articles, each written by masters well versed in the difficult art of weaving together several hundred disconnected papers into a readable whole. The activation of the zymogens, reviewed by Neurath, and the conversion of fibrinogen to fibrin, reviewed by Scheraga and Laskowski, are chemically related phenomena. Each involves the activation of a precursor by the hydrolytic action of a specific enzyme. It is only in the conversion of trypsinogen to trypsin, however, that the process has been fully elucidated, while the activation of chymotrypsinogen, procarboxylase, pepsinogen and fibrinogen each consists of a different and complex proteolysis as yet only partly understood. In fibrinogen, moreover, the splitting by thrombin is followed by a polymerization, the intricacies of which challenge the physical chemist. The discussion of these phenomena becomes highly technical, but both articles contain lucid summaries for the non-specialist.

Literature on the chemical nature of antibodies is a jungle of confusing observations through which Isliker guides us with skill. Their purification, and the complexities of even the simplest immune reaction by whole animals, baffle the biochemist. Decisive advances probably await the production of antibodies by homogeneous cultures of specific cells or, even better, by microsomal particles extracted from them.

Li's short article reviews the structure and biological activity of the melanocyte-stimulating hormones, including the most recent results by himself and Harris on the relations between these hormones and adrenocorticotrophic hormone. Work on prolactin, an interesting protein of molecular weight 24,000 with a cystine bridge screening the terminal carboxyl group, is also described.

The abnormal hæmoglobins are a new field to which Itano has made outstanding contributions; his paper gives a lucid summary of the observations and a thoughtful discussion of the physiological, chemical and genetic problems they raise. I should have thought it an understatement, though, to describe Ingram's work on the chemical differences between normal and abnormal hæmoglobins as a "significant advance".

"Protein Crystallography without Tears" might be the title of Kendrew and Crick's article, a popular exposition spiced with pictures of mermaids and quotations from "Alice in Wonderland". However, the frivolous tone conceals scientific rigour in an introduction to crystallography for the non-physicist. This is followed by a balanced account of X-ray work on fibrous and globular proteins, the latter now fortunately rendered obsolete by Kendrew's three-dimensional Fourier analysis of myoglobin.

Goodman and Kenner's monograph on peptide synthesis describes the newer synthetic methods, followed by more than a hundred pages of tables with data and references for all the peptides ever made.

The book is a mine of useful information and should be on the shelf of every biochemical department.

M. F. PERUTZ

TEXT-BOOKS OF ZOOLOGY

Borradaile's Manual of Elementary Zoology

Thirteenth edition, revised by W. B. Yapp. Pp. viii+769. (London: Oxford University Press, 1958.) 30*s*. net.

General Zoology

By Mary J. Guthrie and Prof. John M. Anderson. Pp. xv+708. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 60*s*. net.

General Zoology

By Claude A. Villee, Warren F. Walker, Jr., and Frederick E. Smith. Pp. xix+877. (Philadelphia and London: W. B. Saunders Company, 1958.) 52*s*. 6*d*.

THE authors of these books set out to provide a text for a first course in zoology. "Borradaile's Manual" is the thirteenth edition of a standard work which many generations of students found well written and intelligible, and this last revision, coming so soon after the major one in 1955, was in response to criticism concerning illustrations, misprints and errors which then appeared. Guthrie and Anderson's "General Zoology" is planned to replace a standard American work—Curtis and Guthrie's "Textbook of Zoology"—but in preference to a fifth edition an essentially new book has been written which preserves characters of the old, brings the text up to date and introduces an insight into modern trends of zoology. As in Villee, Walker and Smith's "General Zoology", the authors set out to give a comprehensive understanding of the subject, recognizing that anatomy is a prerequisite to an appreciation of the functioning of organisms.

The last two books deal initially with cell physiology, metabolism and reproduction and give the necessary chemical and physical background. A survey of the invertebrates follows and some comparative anatomy of vertebrates (which receives a broader treatment in the work by Villee, Walker and Smith), and there are sections on ecology, evolution and genetics. This wide approach to the subject, which reflects its shifting emphasis, necessitates the pruning of some detailed morphology, and one wonders whether such groups as Rotifera, Acanthocephala, Bryozoa and Hemichordata are included for any reason other than reference. The sections on embryology are concise, but it would be helpful to have a precise account of the movements of presumptive areas during gastrulation. Many illustrations in these volumes are new, especially prepared for the text, and others adopted from elsewhere are redrawn. All are labelled so that uniformity is maintained. The drawings in Guthrie and Anderson are executed with great care; in Villee, Walker and Smith more diagrammatic representations are favoured, and this is in conformity with differences in the text and the more leisurely style in Guthrie and Anderson. There are excellent photographs of living animals.

It is a pity that "Borradaile's Manual" still impresses one with its traditional lack of functional treatment, but this would perhaps demand alterations greater than the publishers would welcome in the light of the book's undoubted popularity and its present low price. The introductory chapter on animal organization could profitably be expanded to reflect recent advances. The detailed morphology, an essential constituent of the type system (in which the reviewer firmly believes), gives guidance in practical work (though scarcely replaces a practical text), but needs supplementary comparative studies to give a better understanding especially of vertebrate evolution. A large number of illustrations (forty-three) have been replaced, and more replacements are promised. Figures have been compiled from a variety of sources, and unfortunately this is reflected in their labelling, which has not been altered and results in an incongruity of style and information which is distracting to the beginner. V. Fretter

NATURALLY OCCURRING QUINONES

Naturally Occurring Quinones

By Dr. R. H. Thomson. (Organic Chemistry Monographs.) Pp. vii+302. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 50s.; 9 dollars.

THIS interesting class of natural products claimed the attention of organic chemists at an early date on account of the importance of some of its members as dyestuffs; and interest in them has continued ever since and has greatly increased in recent years. They vary in complexity from simple derivatives of benzoquinone through the numerous naphthaquinones and anthraquinones to polycyclic molecules like erythroaphin and hypericin.

In this excellent monograph Dr. Thomson has given a critical account of the chemical investigation of all the natural products that have been isolated, characterized, and identified with fair probability as quinones. He has wisely included a number of compounds that are not in fact quinones, such as the sennosides, barbaloin, and rugulosin, the chemistry of which is so bound up with that of related quinones that their omission would have been rather artificial; on the other hand, he has omitted compounds such as methylene-quinones and phenoxazones which contain quinonoid systems that are not terminated at both ends by carbonyl groups. The great volume of degradative work published on some members of the group is concisely summarized, and the more interesting points in their chemistry, such as the unexpected cyclizations and molecular rearrangements that often puzzled early workers in this field, are fully discussed in the light of more modern results and ideas. The degradations and syntheses described are made easy to follow by the generous provision of structural formulæ. Special care has been bestowed on the listing and nomenclature of the animal and vegetable sources, for which there are separate indexes in addition to the main index. There is an extensive bibliography appended to each chapter with references ranging in age from the Old Testament up to as late as 1957, and there are interesting sidelights on the history and uses of many quinonoid pigments.

This volume is indispensable as a reference book for anyone interested in natural colouring matters, and the reviewer also found it a pleasure to read.

R. I. T. Cromartie

AVIATION MEDICINE

Aviation Medicine

Selected Reviews. Edited by Clayton S. White, W. Randolph Lovelace II, and Frederic G. Hirsch. (AGARDograph No. 25.) Pp. vii+305. (London and New York: Pergamon Press, 1958. Published for and on behalf of Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization.) 70s. net.

THESE reviews summarize some recent developments in analytical techniques and instrumentation of use to research workers in the highly specialized fields embraced by aviation medicine.

The relation of some of the material to aviation medicine is tenuous. A. E. Reif contributes a lengthy chapter on the physical properties of aerosols, some of which is out of place in a book such as this. Similarly, T. L. Chifelle's chapter on technical developments in pathology is not wholly relevant, making no mention of aviation medicine: nor does Chifelle mention the promising field of aviation pathology.

I. G. Bowen contributes a useful review of techniques for the measurement of atmospheric ozone and outlines a programme for determining whether or not ozone is a hazard. M. A. Palmer summarizes recent developments in high-speed photography, but fails to give an adequate explanation of image fixation on continuous film cameras. J. Clark contributes a short chapter on pressure transducers and Frederic Hirsch has written a useful review of temperature-measuring techniques. Hirsch omits any reference to radiometry, which perhaps deserves mention, and is mistaken in suggesting that thermocouples can be used to measure absolute zero. B. B. Longwell reviews methods for investigating some of the biochemical and physiological changes which occur during stress.

The remaining chapters are devoted to respiratory physiology.

U.P. Luft surveys the important features of various techniques used in direct spirometry and residual volume determination, but omits bronchospirometry and the measurement of maximum breathing capacity and timed vital capacity.

Clayton S. White has written a comprehensive review which describes the physical methods that have been developed for the analysis of respiratory gases. The paper covers methods based upon the measurement of thermal conductivity, paramagnetism, refractive index, velocity of sound, and absorption, mass and emission spectra. It is in the field of emission spectra that the author has made a significant contribution to this aspect of respiratory gas analysis. This section also contains an extremely useful collection of references. It suffers, however, in that it is not sufficiently critical and an investigator new to the field receives little guidance as to which is the best method to employ in given circumstances.

In a further paper written in collaboration with W. R. Lovelace II, White discusses in detail the use of the nitrogen meter. This section is full of intensely practical details with regard to the calibration, accuracy and use of this instrument. In the opinion of the reviewer it should be read by anyone who proposes to use this important tool of the respiratory physiologist.

The final paper, by N. P. V. Lundgren, presents a comparison of the Rahn-Otis sampler with a method for obtaining end-tidal air from the oropharynx. He does not consider, however, the generally accepted limitation of end-tidal air sampling as a method of determining the composition of the alveolar air during quiet breathing, when the volume of alveolar air is inadequate to wash out the respiratory dead space.

All the reviews in this book are by American authors. Most of the material is of great value to the specialist in aviation medicine. Some of the material, excellent in itself, would have more impact in a different publication.

BIOLOGICAL INFORMATION: THEORY AND PRACTICE

The Biological Replication of Macromolecules

Edited by F. K. Sanders. (Symposia of the Society for Experimental Biology, No. 12.) Pp. vi+255. (Cambridge: At the University Press, 1958. Published for the Company of Biologists on behalf of the Society for Experimental Biology.) 50*s*. net.

At the present moment considerable interest is centred around the mechanisms involved in the transfer of intelligence in biological systems, particularly with respect to the relationship which is believed to exist between the structure of two types of large molecules found in all living organisms, namely the proteins, which were originally regarded as the fundamental molecules, and the nucleic acids, which are now thought by many to be the repository of all the information required by an organism. Unfortunately, although this relationship is probably one of the most important in biology, experimental evidence for it is somewhat slight and may even be conflicting. Thus, for example, several enzyme systems are now known which will produce reasonable facsimiles both of ribonucleic acid and deoxyribonucleic acid from simple substrates, but there does not appear to be any necessity for a specific coding system for this synthesis, nor do the nucleic acids produced appear to have any particular information content built in. Indeed, such systems will willingly accept substrates which they do not normally encounter, and incorporate them into the polymers.

So far as the proteins are concerned the situation is rather different, because *in vitro* systems do not accomplish much more than incorporate radioactivity from individual labelled amino-acids into material of large molecular size, and they appear to be rather restricted in their synthetic capabilities.

However, in spite of the general paucity of experimental evidence, there is a great deal of effort now being expended in attempts to elucidate the type of code which could relate the structures of proteins to those of the nucleic acids, using methods of the kind employed in cryptographic analysis. Apart from the fact that new constituents of nucleic acids are now being discovered at regular intervals, and that work on small polypeptides has shown the existence of structures so far undetected in proteins, the problem is complicated further by lack of information about polynucleotide sequences, and by the fact that the proteins themselves are coded by a complex transposition code, which relates their catalytic surface structures to the residue sequences in their polypeptide chains. Consequently, it is necesary when engaging in this entertaining pastime to simplify the problems to such an extent as to render the conclusions doubtfully significant.

It was probably with intent to discuss the present implications of this type of work that the Society for Experimental Biology decided to organize a symposium on "The Biological Replication of Macromolecules" which has since appeared in book form. The precise meaning of the rather indefinite term macromolecule seems to have eluded the organizers, and the various contributors interpret it as meaning anything from a small polynucleotide to a nucleus, with a few proteins and polysaccharides thrown in for good measure. The general tendency of the contributors has, however, been to discuss the more complex types of structure, with the result that the emphasis is largely on genetical rather than on biochemical phenomena. Outstanding among these papers is an account of the conjugation process in *Escherichia coli K*12, while other papers discuss hereditary mechanisms of bacteria, and phenomena occurring on tumour tissue transplantation and during virus replication.

On the simpler level, there are accounts of remarkably successful attempts to isolate individual nucleic acids by ion exchange, and several papers on protein synthesis including an authoritative exposition of the rules of 'coding'. The general impression given by these papers is that a lot of experimental work is still necessary before the results can be interpreted.

It need scarcely be said that all the articles are of a high standard, and it is regrettable that a volume containing such a wealth of information should not contain an index. Roy Markham

MUSICAL ACOUSTICS

A MEETING of the Acoustics Group of the Physical Society, under the chairmanship of Mr. T. Somerville, was held at the Royal Academy of Music on February 26 to discuss : "Of what Use is Acoustics to the Musician ?". Prof. E. G. Richardson opened the proceedings by introducing a list of possible uses of acoustic knowledge and apparatus, as follows.

To obtain an accurate tuning note. This is an obvious use for an electronic oscillator, amplifier and loud-speaker. The conventional instruments for giving the key-note (in singing) or *A* (in playing) are the tuning-fork or the pitch-pipe or the note given by a wind instrument, usually the oboe in the orchestra. The last two suffer from temperature uncertainties, though there is some advantage in having the oboe giving the *A* since the pitch reached by the player after warming up, even if not precisely 440 vibrations per second, will be one to which all the wind players can conform.

To check the pitch of a recorded performance and of the correct intonation of the different parts in concerted music. This is an interesting pastime which tells one quite a lot, perhaps too much. By its means it is possible to check the intonation and pitch discrimination of a solo instrumentalist or singer during a performance. It also brings out quite prodigious feats of tuning and re-orientation of pitch on the part of a good orchestra. Thus, as was shown by an analysis made of a Dutch tape-recording, at a certain performance of Beethoven's first pianoforte concerto the piano was at 440, to which the orchestra tuned within 1 c./s. When accompanying the soloist the orchestra accommodated itself to his pitch, but rose 2 c./s. higher in the *tutti*. On the other hand, a rather regrettable state of affairs was disclosed in a broadcast of Bach's oboe concerto. Oboe and orchestra tuned to 440, but when the piano came in it was at 435. It says much for the string players that they overcame this handicap by playing at 439 (to which the oboe had dropped) when accompanying the solo, and at 435 in the ensembles with piano.

The pitch generally tends to rise above the tuning note during *forte* passages, probably because the notes of the wind instruments tend to rise in pitch with the blowing pressure. The tests also showed—what has been long known—that the human voice at its best is by no means so precise in maintaining constancy of pitch as the mechanical instruments.

The fact is that a musician may be most meticulous about notes being in tune at one instant and will tolerate a considerable degree of mistuning at others. It is natural that he should wish the notes of prominent diatonic chords in a composition to be in tune, but care less about passing notes, which may be elided rapidly, or the little unaccented grace notes which the composer writes as a semi-tone above or below a prominent chord note, probably with no intention that they should be rendered as semi-tones. It is also natural that singers asked to descend a semi-tone and return to the original note, in a type of cadence prominent in the sixteenth century, should make the drop less than a semi-tone in anticipation of rising again. It is a question of accent and speed.

To establish a succession of notes to form musical scales. The construction of a musical scale stretching from one note to the other and the historical evolution of scales seems to me a rather arid and arithmetical subject of study.

Whether our musical sense is an occidental or an oriental one, we all seem to agree that the scale shall cover an octave (though it is true that, in modal counterpoint, the 'stretch' was regarded on occasion as exceeding the octave). Also, rather surprisingly, we all seem to divide the octave of the scale into seven steps whether these are based as in Western music on tones and half tones, or whether, as in Eastern music, some of the intervals are third or quarter tones. In physics, we are mostly Pythagoreans, that is to say, we think of the octave as a length of stretched string which is sub-divided into shorter pieces of string bearing fixed ratios to the whole, but throughout the ages there has existed a type of musicologist who conceives—to me—more complicated sub-divisions, which he advocates as *the* perfect scale.

For most of us two scales suffice, the major and minor of just temperament. Formerly, as is well known, there were six scales in Western music, all having two semi-tone intervals placed at different points in the scale and rejoicing in the lovely names of Dorian, Phrygian, Lydian, Mixolydian, Aeolian, Ionian (thinking in terms of the pianoforte we can say that these had as key-note in turn *D, E, F, G, A* and *C*, but were entirely made up of the white notes). Of these, that based on the note *C* became the major and that on *A* the minor scale. Later, when composers learnt to harmonize, they wanted to make a composition modulate into other keys, and although this was possible for singers and for players on the viols and sackbuts of the epoch, it was not so on a wind instrument with side holes, or on instruments with keyboards, because the frequencies of some notes on the new tonic (key-note) were not equal to any of those of the old key. So a compromise had to be reached, and after various trials the equi-tempered scale, in which the semi-tone is equal to the twelfth root of two, received the support of Bach (who wrote for it his "48 Preludes and Fugues") and became established.

An orchestra or a choir then, accompanied on a keyboard instrument, had to follow equal temperament. Singers, who in common with string players and trombonists have the pitch of the tones they produce variable at will, often claim that when singing unaccompanied (*a capella*) they use the untempered scales. But they are not justified by pitch analyses which have been made using tape records in the way already mentioned. Hard facts show that both they and unaccompanied string quartets use a temperament which is mid-way between the just and the equi-tempered. It is, of course, possible to hear music played on keyboard instruments in just temperament, in a limited number of keys. Such instruments have red and green as well as black and white keys, but require an expert to play on them.

To provide a scientific basis for theories of harmony. It is impossible in a short space of time to give a complete history of the ideas of consonance and dissonance of intervals. It is well known that Helmholtz gave the physicist's and physiologist's view of the basis of dissonance. To him it was a question of the relative number of beats between two tones sounded together as a chord. The more frequent these, the greater dissonance. He made a graph showing the number of beats for each interval of the major scale. But to a musician these matters are not so simple. In fact, some of the ideas of Helmholtz on this question of discords have since been discredited.

In classical music the striking of a discord is rather like the tasting of wine or of sauce. The ear, like the palate, has to be prepared for it ; it is then savoured and it should be followed by some contrasting sweeter sensation.

This was how it was with discords in the classical period of harmony. At first only the octave and the fifth were regarded as concords. It is supposed that the other intervals evolved in the theory of harmony on the basis of a series of upward jumps of a fifth and downward jumps of a fourth. In this way the major and minor thirds appeared and also the seventh. At first the fourth was regarded as an imperfect interval, but by the fifteenth century the root tone, third and fifth formed the accepted concord. Only when the third above the fifth was added to form the seventh above the root of the chord was a discord felt, and this discord had to be prepared by first appearing in a concord and resolved on the following chord in a special way. Later, other thirds were added above the seventh to give the ninth and the eleventh.

It was Bach who found that the discord could be made more piquant by not preparing it, and since his time a composer has followed his whim in this matter. In turn, the necessity for resolution has ceased to be felt by composers. Wagner did not resolve ninths, and Ravel treated elevenths as consonances.

To me the necessity for resolution and not the counting of beats is the essence of a discord. If I do not feel, for example, the seventh on the fifth note of the scale to lead on naturally to the chord on the key-note or any other concord, that chord is free in its progression and so becomes for me a concord.

To measure the acoustic spectra of musical instruments in order to study and improve functioning. Perhaps this is the most rewarding service which the scientist can perform. There exist firms in the musical instrument trade, perhaps more numerous in the United States and Germany than in Britain, which are well aware of the possibilities of acoustic spectrometers and employ people competent to operate them. Adjustments are then made, for example, in the thickness of the belly of a stringed instrument, in the metal of an organ pipe, so that the 'voicer', or his counterpart outside the organ-building trade, can observe the effect on the formant of the instrument which in turn governs the spectrum and the efficiency of the instrument. Not only are such studies carried out by employees of firms, but physicists who are also music amateurs have spent a lifetime of leisure in such work. One need only refer to what Dr. F. A. Saunders has done for the violin and viola in Massachusetts and Dr. W. Lottermoser for the organ (and certain other instruments) in Eastern Germany.

To make experiments with new spectra (on electronic musical instruments). The advent of the electronic organ has given harmonic innovators a very useful tool to try experiments on, though they do not always realize that the loud-speaker of the instrument can superpose its own formant on the register in which the player elects to play his new-fangled music. This new electronic composing is not very popular in Britain, but there exist flourishing groups of its exponents in Germany, Italy and Switzerland.

To obtain design data on concert halls and music rooms. Perhaps in this matter, the musician especially realizes his debt to the scientist who works in acoustics. Auditorium acoustics must remain largely subjective, and musicians reserve their right to say when a hall is good for the performance of music—the difficulty is that all do not speak with one voice on such topics. Nevertheless, when composers and performers are able to say what they want—in reverberation, relative weight to different parts of the gamut and so forth—the acoustic consultant is usually able to advise the architect so that a concert hall or music room satisfactory to its users results.

Dr. B. W. Robinson, continuing the discussion, said that most musicians got on quite happily without studying acoustics. Also, he thought that not many instrument makers used the precision electronic apparatus now on the market for calibrating their products. Prof. Richardson had, however, omitted to emphasize the importance to a musician of the latest high-fidelity reproducing equipment, which was a great boon to an artiste wishing to judge, after listening to himself, to what extent his performance had improved. Self-recording was also of use in teaching elocution, and for singers to show them how bad their pitch discrimination often is.

Mr. D. M. A. Mercer said that acoustic testing with modern equipment could teach the craftsmen tricks not in the text-books and enabled the organ builder to determine how many stops would be required on an organ design for a new church. By its means, Dr. R. W. Young in America had been able to formulate the best tuning system for a pianoforte. This was never done exactly in accordance with the equi-tempered scale.

Dr. A. E. Brown said that he found a knowledge of acoustics helpful in learning to play a musical instrument, for example, in forming the best embouchure for the French horn.

Mr. A. Rakowski referred to the importance for music of having people trained to take full responsibility, from the artistic point of view, for making musical recordings. In the present state of perfection of sound technique in disk recording, radio and film, it is possible for recorded music to achieve a very high degree of artistic value, but people who work in the technique should have a knowledge of both acoustics and music. In the Music Academies of Warsaw and Detmold, special courses have been established for training such personnel.

Dr. H. D. Parbrook thought that there was too much of the music student's time devoted to theoretical study of scales and tuning. Not enough attention was paid to the tonal qualities of electronic musical instruments.

Mr. Nightingale also emphasized the importance of the tape recorder to the virtuoso to improve his playing.

Dr. H. Lowery recalled Sir Hubert Parry's dictum that the acoustical knowledge of a student varied inversely as his knowledge of music. He thought there still was too big a gap between the teaching of acoustics and the requirements of the musician. He said that an understanding of auditorium acoustics was most important to the composer. It was because Bach had an instinctive knowledge of this that his works were so well adapted to the baroque style of building which was prevalent in his day.

E. G. RICHARDSON

VAN ALLEN RADIATION OF SOLAR ORIGIN

By Prof. PAUL J. KELLOGG
University of Minnesota, Minneapolis

A NUMBER of authors[1] have proposed that the radiation discovered by Van Allen and co-workers[2] results from the decay of neutrons produced in the Earth's atmosphere by cosmic rays. There is some doubt, however, as to whether the low-energy (< 1 MeV.) radiation near the Earth, which on this hypothesis would be due to the β-decay electrons from thermal neutrons[3], is not too intense to be attributed to this source. Although the albedo source is not yet completely ruled out, one should consider other sources for the Van Allen radiation.

The Van Allen radiation is observed to be divided into two zones, and it has been suggested that the inner zone results from neutron albedo, while the outer zone is due to solar particles. This suggestion may be right, but does not help if the inner zone radiation is too intense to be accounted for on the albedo hypothesis. Nevertheless, streams of solar particles are very likely candidates as sources of Van Allen radiation and it is necessary to consider them in more detail.

The picture of the Van Allen radiation which we shall present is rather similar to that published by Gold[4]. We suppose with Gold that part of the Van Allen radiation has its origin in streams of solar gas which somehow become trapped in the Earth's magnetic field. The mechanism for this trapping is not understood, but it is reasonable that, since the pressure of the Earth's magnetic field varies as r^{-6}, most of the gas is injected at a rather constant distance from the Earth. The particles of the gas diffuse away from their radius of injection, but the mechanism for diffusion which we shall present is different from that suggested by Gold.

It is a well-known result of the perturbation theory of the motion of a particle in a slowly varying magnetic field that the magnetic moment of the particle due to its helical motion is a constant of the motion to a high degree of accuracy. Our diffusion mechanism maintains the constancy of $W_{\perp}/B$, so that particles which diffuse toward the Earth into regions of stronger magnetic field must also acquire energy. We discuss this acceleration in detail below. As the particles diffuse upward and downward they may also be lost to space or into the Earth's atmosphere.

This picture might explain the presence of the two Van Allen zones. With Gold, we assume that injection usually occurs at 5–7 Earth radii. Thereafter, the particles diffuse inward and outward, those going outward being lost in a short time. If the diffusion is very rapid in the region beyond 4 Earth radii and considerably slower in inner regions, then the position of the maximum density will move inward as the diffusion proceeds. We discuss below a possible reason for faster diffusion beyond a few Earth radii. It seems reasonable to suppose that the injected particles have an energy spectrum such that the bulk of the particles have too low an energy to be recorded by the instruments used by Van Allen (~ 15 MeV. threshold for protons) but that some few have sufficient energy. Then we expect that the counting-rate will be high near the Earth, where many of the particles have been accelerated to high energy, and high near the injection point, where there are very many particles, but may be low in between, where many particles have been lost and too few have been accelerated to energies above the detector threshold to make up the deficit. In this picture, of course, the total density of particles in the part of the Van Allen radiation of solar origin continually decreases inward from the region of injection and the dip in counting-rate between the two zones is only an effect of the detector threshold.

In order to illustrate the mechanism for acceleration of the particles in the Van Allen radiation, we consider first the following simple case. Consider a system with a constant electric field in the x-direction and a magnetic field in the z-direction which varies in the y-direction, and consider charged particles moving in the $z = 0$ plane. The constancy of the magnetic moment to high accuracy for this case has been demonstrated by Kruskal[5]. According to the Alfvén perturbation theory[6] of motion of particles the radiation of gyration of which is small compared to the scale of field variation, the electric field causes the particle to drift in the y-direction, with velocity v_y. The gradient in B_z causes the particle to drift in the x-direction with velocity v_x. Here:

$$v_y = -c\frac{E_x}{B_z} \qquad v_x = -\frac{c}{e}\frac{W}{B_z^2}\frac{dB_z}{dy} \tag{1}$$

where W is the energy of the particle. The gradient in the magnetic field, therefore, carries the particles into regions of higher or lower potential, depending on the signs of E_x, B_z and dB_z/dy. Since the total energy is constant, the kinetic energy will be decreased or increased. Rather extreme examples of these orbits are illustrated in Fig. 1.

Now we consider the motion of particles trapped in the field of the Earth. As is well known[4], the particles have a very fast gyration around the lines of force, a somewhat slower back-and-forth motion along the lines of force, and a still slower precession around the Earth due to the gradient of the Earth's field. It is this last motion which is of importance here. Since the Earth's field is somewhat irregular, the gradient will cause the particle to precess faster at some longitudes, slower at others. We consider two sources of electric field. First, during a magnetic storm the changing magnetic field of the Earth will produce electric fields. Secondly, various collective oscillations, in particular flute oscillations, may produce electric fields.

We cannot discuss flute oscillations properly at the present time, because we do not understand them. The criterion given by Longmire and Rosenbluth[7] for flute instability, namely, that the magnetic field confining the plasma be convex outward, cannot

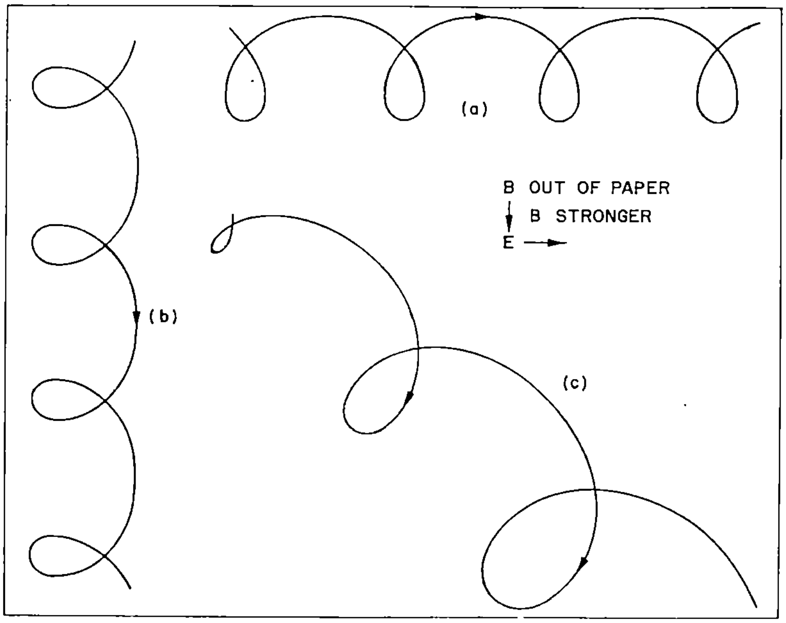

Fig. 1. Typical particle orbits: (*a*) $E = 0$, drift produced by gradient of B; (*b*) $dB/dy = 0$, drift produced by E; (*c*) combined effect of E and dB/dy

be correct, or the Van Allen zone would not be able to trap any radiation; it would be flute-unstable at its upper boundary. It can be shown that neither the conductivity of the background gas, nor 'thermal' dispersion of the particles which would smear out the flute oscillations before they could develop, is sufficient to prevent growth of instabilities at distances less than about 100 Earth radii. Longmire and Rosenbluth neglect the change in energy of the magnetic field, which seems incorrect since the energy of the field is reduced by a quantity of the same order as the plasma energy, and it is probably this neglect which makes their treatment inapplicable in the present case. Intuitively, we might expect that a magnetic field would be rigid enough to confine a very low density of plasma, and that the condition for flute instability should involve the ratio of plasma energy density to field energy density. We may therefore speculate that flute instabilities may be important in the outer parts of the Van Allen radiation, where the field is weak, may account for the approximate r^{-6} decrease of its intensity, and may produce a much faster diffusion in this region.

Both these electric fields have zero time average, so that if the Earth's magnetic field had rotational symmetry they would not produce any net change of particle energy. However, in conjunction with the space-varying gradient of the Earth's field, acceleration and deceleration may be produced. For example, suppose the electric field has a positive value E for a time t and a negative value $-E$ for the same length of time. While the electric field is positive the magnetic field gradient will carry the particle through a potential difference eEv_1t, and while it is negative the particle will be carried through a potential difference $-eEv_2t$, where v_1 and v_2 are average precessional velocities produced by the gradient of the Earth's field at the appropriate longitudes. If $v_1 > v_2$ then the particle will have a net gain in kinetic energy:

$$eE(v_1 - v_2)t \qquad (2)$$

and vice versa. The magnetic moment of the particle, $W_\perp/B$, will be constant, and so if the particle gains energy it will move into regions of stronger field, and thus nearer the Earth, and vice versa. Thus, the electric fields of magnetic storms coupled with the irregularities in the Earth's field will produce a diffusion of particles inward and outward and at the same time an acceleration of those particles which happen to go inward.

The orbits of the particles can be discussed in more detail using, in addition to the constancy of the magnetic moment, the constancy of the integral $J = \int v_{\parallel} dl$ taken between turning points[7]. We present one result only. As the particles diffuse, their turning points move on lines which are roughly radial.

The use of these two constants is the major difference between the present treatment and that of Gold. Gold assumes that irregularities in the field, or electric fields, separately, can produce diffusion. This can only take place if at least one of J and $W_\perp/B$ is not conserved. In a dipole field, the orbit of the particle's guiding centre can be specified by giving three parameters, for example, the energy of the particle, its pitch angle at the equator, and the distance from the Earth at the equator. If in addition to J and $W_\perp/B$ the energy of the particle is constant, as it would be in the case of static magnetic fields of whatever irregularity or of slowly varying electric fields the time average of which is zero, then the particle cannot diffuse but follows a prescribed orbit, the three parameters of which are determined by the three constants of the motion.

Gold's treatment implies that J is not constant. Unfortunately, no estimates exist for the rate of change of J, and so the efficacy of his diffusion mechanism cannot be estimated.

We now make a very rough estimate of the rate of diffusion. Since Van Allen particles do not approach nearer than 1,000 km. to the Earth, they will not be affected by irregularities in the Earth's magnetic field of scale much less than 1,000 km. We may expect, then, that the principal irregularity will be that produced by the Earth's octupole moments, which contribute about 10 per cent of the Earth's surface field. The wave-length of the field is one-third of the Earth's circumference, so that particles which precess around the Earth will be most strongly affected by those Fourier (time) components of the electric field which have the same period as the time the particle takes to precess one-third of the distance around the Earth. This time is given by a modification of equation (2):

$$\tau = \frac{1}{3}\,\frac{2\pi R}{\dfrac{c}{e}\,\dfrac{W}{B^2}\,\nabla_\perp B} \approx 10^4 \left(\frac{R_E}{R}\right)\left(\frac{1}{W}\right) \qquad (3)$$

where W is the energy of the particle in MeV. and τ is in seconds.

During magnetic storms the magnetic field-changes have periods of a fraction of a minute to a few hours.

Only particles of energy greater than 1 MeV. are, therefore, able to take advantage of these changes. For particles of lower energy a different approximation must be used. We take $300\gamma = 3 \times 10^{-3}$ gauss as a typical change of the magnetic field in this time and E approximately equal to $R\mathrm{d}B/c\mathrm{d}t$

$$\approx 3\,\frac{R}{c}\,\frac{10^{-3}\text{ gauss}}{\tau}$$

The change in energy during one cycle of the electric field is given by equation (2). Since B varies by 10 per cent at the surface and decreases as $1/R^2$ compared to the dipole part, we may expect $(v_1 - v_2)$ to be of the order of $\frac{v}{10}(R_E/R)^2$ and vt to be one-third of the orbit circumference. During one cycle, then, we estimate:

$$\Delta W = eE\,\frac{vt}{10} = W\left(\frac{R}{B}\frac{\mathrm{d}B}{\mathrm{d}z}\right)\left(\frac{3\times 10^{-4}\text{ gauss}}{B}\right)\left(\frac{R_E}{R}\right)^2 \quad (4)$$

$$\approx W(10^{-3})\,\frac{R}{R_E}$$

Over a long period, T, since this is a diffusion phenomenon, the root-mean-square (r.m.s.) change $\Delta W/W$ will be proportional to $\sqrt{T/\tau}$. Here T is counted only during magnetic storms. We estimate that magnetic storms are going on 0·1 of the time, and so:

$$\frac{\Delta W_{\text{r.m.s.}}}{W} = 10^{-3}\,\frac{R}{R_E}\sqrt{\frac{T}{10\tau}} \quad (5)$$

where T is now total elapsed time. The time (in seconds) for the particle to make a change of a factor of 2 in its energy is of the order of:

$$T_2 = 10^7\left(\frac{R_E}{R}\right)^2 \tau = 10^{11}\left(\frac{R_E}{R}\right)^3\left(\frac{1}{W}\right) \quad (6)$$

with W in MeV.

This estimate is very rough and is certainly not to be trusted to within a factor of 10. As it stands, however, it gives a diffusion time of 10^9 sec. for a 10-MeV. particle at two Earth radii, which is about 1,000 times shorter than the scattering time for protons, and comparable with that for electrons. The estimate is not valid for particles of energy less than 1 MeV., but an appropriate approximation in that case indicates a diffusion time of the order of 10^{11} to 10^{12} sec., which is somewhat longer than the scattering life-time of either protons or electrons. The diffusion is therefore not capable of supplying low-energy particles to the inner Van Allen zone, as they will be scattered down into the Earth's atmosphere before diffusing very far. Of course, low-energy particles of solar origin might still be supplied directly to the inner zone during times of low-latitude auroræ.

In our opinion, the outlook for Gold's diffusion mechanism is similarly pessimistic. The rates of change of the two near constants of the motion, $W_\perp/B$ and J, are probably very rapidly varying functions of the particle momentum, since the asymptotic expansion, for $W_\perp/B$ at least, vanishes to all orders[5]. The intensity of high-energy particles shows that they are trapped for a long time, so diffuse fairly slowly; therefore, the low-energy particles probably diffuse even more slowly than by the mechanism considered here. We are therefore left with neutron albedo, low-latitude-auroral streams and, possibly, high-altitude nuclear explosions, as the possible sources of the low-energy Van Allen radiation in the inner zone.

I wish to thank Prof. T. Gold for helpful discussions concerning both the present article and his own theory of the Van Allen radiation, and also Profs. E. P. Ney and J. R. Winckler.

A NEW THEORY OF THE SOLAR CORONA

By Prof. PAUL J. KELLOGG and Prof. EDWARD P. NEY

School of Physics, University of Minnesota, Minneapolis

In the following discussion we will consider the experimental facts which are known about the solar corona and show that these facts are consistent with a model of the corona quite different from that currently accepted.

According to the present model, the solar corona consists of a gas of electrons and protons with a small mixture of heavy elements which is isothermal at a temperature of approximately a million degrees and which is in hydrostatic equilibrium in the gravitational field of the Sun. The alternative model which we propose is that the solar corona consists of trapped charged particles moving in the magnetic fields of the Sun, very like the charged-particle cloud surrounding the Earth which has recently been discovered by Van Allen[1] and his collaborators.

Although hydromagnetic effects in the solar corona have been discussed (see, for example, Alfvén[2]), the idea of the corona as a trapped charged particle assembly has, to our knowledge, not been proposed.

The solar corona is usually said to be very much hotter (10^6 deg.) than the bodies in contact with it (6,000° for the Sun, 100° for the outer boundary). It is not known what supplies its energy, but probably the heating is a hydromagnetic effect produced by the turbulent motion in the outer part of the Sun, or by 'granulation waves', as suggested by Schwarzschild[3]. There is no general agreement as to the details of this heating mechanism, nor as to the particle energy spectrum which it produces. A lower limit to the supply of energy to the corona may be easily set by computing known losses of energy such as radiation in the observable regions and evaporation from the outer corona. Van de Hulst[4] estimates that the whole energy of the corona must be supplied every 10^5 sec. This time is so short that many features of the corona cannot be expected to be in thermal equilibrium. For example, the collision time for an electron at one solar radius above the surface, where the density is 10^6 electrons/cm.^{3}, is of the order of 10^2 sec. for a 100-eV. electron but is about 10^5 sec. for a 3-kV. electron. Therefore, if the heating mechanism accelerates some electrons to energies greater than 3 kV., these electrons may have energy supplied faster than they lose it by collisions. We may expect, therefore, that in small regions of the corona those electrons having energies in the vicinity of 100 eV. have approximately a Maxwellian distribution of energies, but there may very well be a very long tail of high-energy particles on this distribution. Since the time for exchange of energy between heavy ions and electrons is much longer than that for particles of the same mass, we may expect that the electrons may have a different 'temperature' from the ions, where now temperature refers only to the Maxwellian distributed part of the energy spectrum.

It is likely that the corona contains magnetic fields of 1–10 gauss so that a 100-eV. electron has a radius of gyration of about 10 cm. In 10^5 sec. and with a collision time of 100 sec. such electrons diffuse only a negligible distance. We cannot, therefore, expect that the corona is in anything like equilibrium with a distribution given by the Boltzmann factor $\exp(-MG_m/RKT)$.

Deviations from thermal equilibrium are, in fact, required by the observations. The high temperature, or more properly energy content, of the corona is deduced from: (1) the scale height of the corona; (2) ratios between the populations of ionization states of heavy atoms; (3) Doppler broadening of emission lines; (4) measurements of radio intensity; and (5) Doppler broadening of the Fraunhofer lines. All these measurements give different temperatures (except 5, which gives only a lower limit). We can understand this if the different processes are affected to a different degree by the lack of thermal equilibrium.

In the following we will discuss the properties of the corona listed above in terms of their present interpretation together with their explanation in terms of our suggestion. In addition, we will consider certain observational facts about the corona which are ignored in the current interpretation, but which, however, can be understood on the basis of plasma trapped in a solar magnetic field.

Scale Height of the Corona

Observations of the brightness distribution of the corona during eclipses show that this brightness varies approximately as $1/R^6$, where R is the distance from the centre of the Sun. This experimental fact, first discovered in the eclipse of 1898, is sometimes referred to in the literature as Turner's law. This observation is the basis for the determination of electron densities in the corona on the assumption that the visible light is Thomson-scattered by free electrons. A brightness distribution varying as $1/R^6$ implies an electron density which varies as $1/R^5$ because of the geometry of the problem. Fig. 1 shows a plot of the inferred electron coronal densities and a graph of the expected electron densities for an isothermal atmosphere held by the gravitational field. We have also shown in this figure the profile of intensity of the Van Allen radiation, in units of the Earth radius rather than in units of the solar radius as is done for the corona observation. It can be seen that the principal difference between the observed coronal electron densities and the number of particles in the Van Allen radiation is that the Van Allen radiation has a pronounced maximum where the corona electron density apparently does not. At large distances from the trapping object, however, it appears that the decrease in intensity of the Van Allen radiation is very much like the decrease of electron densities in the corona.

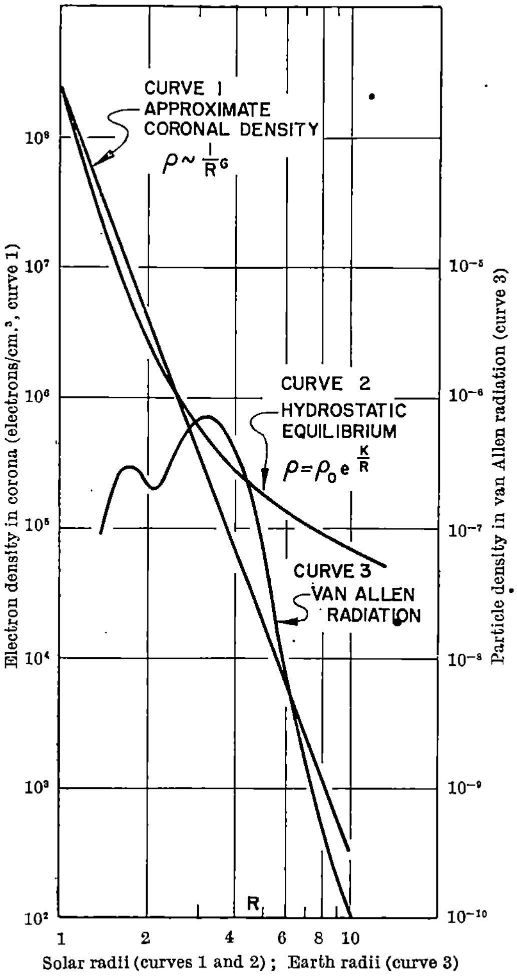

Fig. 1. Plot of electron densities in the corona and Van Allen radiation around the Earth. Curve 1, coronal electron densities vs. radius from the centre of the Sun measured in solar radii; curve 2, an arbitrarily normalized hydrostatic equilibrium curve, such as would apply to the million degree isothermal corona; curve 3 (scale at right), inferred particle densities in the Van Allen radiation (ref. 12) obtained from *Pioneer III* data by multiplying the counting-rates reported by Van Allen and Frank by a factor of 5×10^{-11}. This is equivalent to assuming that the particles measured by them are relativistic particles

Reference to Fig. 1 shows that the particle densities in the solar corona and in the Van Allen belt around the Earth are in approximately the ratio of 10^{12}. If it is assumed that the solar source injects particles which could be trapped in either field, then the flux, because of the inverse square law, would be 10^4 times stronger in the solar belts than in the terrestrial belts. In order to account for the remainder of the factor 10^{12}, one would have to conclude that only 1 in 10^8 of the solar injected particles can be captured at the position of the Earth, that is, the solar trapping field is extremely effective in constraining particles to the immediate solar environment. Because the Van Allen radiation has a maximum and then decreases with increasing distance from the Earth, it is clear that the Van Allen belt is not just an extension of the solar corona, as it could be if Turner's law held to the orbit of the Earth.

Because of the limitations in observing the Sun's corona at large distances from the Sun and because of the *F* corona, it is not possible to distinguish by brightness distribution between a power law decrease of the intensity and the function predicted by hydrostatic equilibrium.

In the hydrostatic model of the corona, Turner's law is the experimental fact, and temperature of a million degrees must follow from the consequent scale height, with a mean molecular weight of 1/2.

The similarity of the intensity distribution at large distances of the corona and Van Allen radiation, however, suggest that the same mechanism may be responsible for both. In a crude way, one can, in fact, justify a power law distribution of intensity of the kind indicated by Turner's law. If the trapping of the high-energy particles were produced primarily by a field with dipole components at large radii, this field would be $B = C/R^3$. Since the energy density of the magnetic field is $B^2/8\pi$, the energy density in the magnetic field can be seen to vary as the inverse sixth power of the distance from the centre of the Sun. In magneto-hydrodynamic models one usually assumes that the energy density of the contained particles is some fraction of the energy density of the field. If this were so, and the energy spectrum were unchanging with distance, the number of particles per unit volume would be expected to go as $1/R^6$. It seems quite clear from observations that the Sun's magnetic field is not a simple dipole field, but the possibility of interpreting Turner's law in a theoretical way as indicated above suggests that magnetic trapping in a more complicated field than a dipole field may be the explanation of corona atmosphere.

Ratios between the Population of the Ionization States of Heavy Atoms

Following the discovery by Edlèn that emission lines of highly ionized atoms were present in the spectrum of the corona, the presence of these emission lines was taken as confirmation of a high kinetic temperature. If these emission lines do, indeed, represent the effect of kinetic theory collisions they also imply an extremely constant temperature throughout the solar corona. For example, the ratio of the intensity of the line due to Fe XIV to that due to the line of Fe X should vary by a factor of about 10^5 for a change in temperature of a factor of 2. It is observed that the ratio of the intensities of these lines varies very little with the solar cycle and with position in the corona.

The hydrostatic model takes this to indicate that the temperature of the corona is extremely constant. On our model the constancy of the ratio of these line intensities would arise because the ionization degree depends on the cross-section for ionization by fast electrons in the high-energy tail. Since the atoms would then be ionized by electron impact by an approximately uniform energy spectrum of particles, one would not expect large variations in the intensity ratio of these lines. It should perhaps be pointed out that the ions themselves would be trapped in the magnetic fields and would therefore not reflect hydrostatic equilibrium of the atmosphere.

Doppler Broadening of Emission Lines

The coronal emission lines are observed to have shapes which are accurately those expected for Doppler broadened lines[5]. The corresponding temperatures, however, range from one to four million degrees, so are both higher and more variable than those derived from (3), yet the same atoms give rise to both effects. On our model, the emission lines would give the 'temperature' of the Maxwellian distributed part of the heavy ion energy spectrum. We suppose there are too few ions in the high-energy tail to affect the line shape.

Measurements of Radio Intensity

The radio emission of the Sun at various wavelengths is sometimes considered supporting evidence for the high coronal temperatures assumed in the hydrostatic theory. The apparent temperature which the radio emission indicates for the quiet Sun varies all the way from 10^4 to 10^{10} deg., with the lower measurements actually applying to chromospheric 'temperatures' because of the wave-lengths used. The range of temperature obtained indicates that the phenomena are too complex to understand on a simple isothermal model, but do not contradict our picture.

Doppler Broadening of the Fraunhofer Lines

In the inner corona, Fraunhofer lines are observed with great difficulty or not at all. This is interpreted to be an indication of a very high kinetic temperature of the scattering electrons which leads to Doppler broadening of these lines to such a degree that they can no longer be seen. The Fraunhofer lines appear again in the outer corona, and this is the primary experimental evidence which leads to the introduction, at large distances from the Sun, of an *F* corona or dust corona composed of large slowly moving particles.

The Doppler broadening differs from the other measurements in that it gives only a lower limit to the temperature. The lower limit is somewhat below 10^6 deg. It is also the one effect which is not strongly influenced by the presence of a moderately small fraction of high-energy electrons. Therefore, the 'temperature' of the Maxwellian distributed part of the electron spectrum may be considerably less than 10^6 deg. This is required by our model in order that the Maxwellian distributed electrons do not produce too high a degree of ionization of the heavy ions.

It can be seen from the foregoing that the principal observational facts about the corona can be equally well, if not better, described by our model than by hydrostatic equilibrium in a gravitational field. There are, in addition, at least three outstanding effects, usually ignored in explaining the solar corona, which have a bearing on the suggestion of magnetic trapping. These are : (*A*) polarization of the coronal light ; (*B*) changes of intensity of the corona with the sunspot activity; and (*C*) the infra-red excess in the corona.

(*A*) *The polarization.* The effort to measure the polarization of the solar corona has a very long history dating back to observations in 1851 by Edlund. Considerable effort was made during the 1930's and 1940's to measure the polarization. Prior to these measurements the suggestion was made by Schwarzschild that the Sun's corona was an electron gas and that the light from the corona came from scattering by free electrons. It should therefore have radial polarization in the sense of the magnetic vector in the electromagnetic wave. Because of the attractiveness of this suggestion, most of the polarization measurements assumed radial polarization and consisted of measurements of the intensity with two analysers at 90° to one another. Such a measurement cannot establish the direction of the polarization.

In only four cases, to our knowledge, has the measurement of the polarization been made with three or more analyser angles in order to determine the direction of the polarization. Van de Hulst[4] in his review article ends his discussion with the remark, "Every time that this method has been used, [to measure the direction of polarization] it has suggested deviations from the normal direction. Theoretically, such deviation seems entirely impossible".

Note added in proof: In addition to the measurements quoted, von Klüber[4a] has observed radial polarization in the eclipse of 1952 (sunspot minimum).

One of our purposes here is to review some of the measurements of the direction of polarization and to consider whether such deviations are actually impossible. The probable source of non-radial polarization would be synchrotron radiation from electrons in magnetic fields. The energies required for the electrons are enormously high—higher than one is used to considering. Conversely, if it proves possible to demonstrate the existence of synchrotron radiation, then previous ideas of the solar corona must be considerably revised.

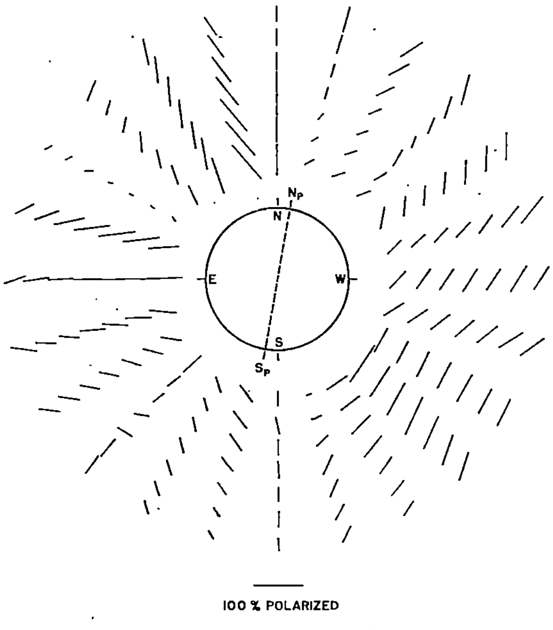

Fig. 2. Plot of magnitudes and directions of the polarization measurements made at short wave-length ($\lambda < 5700$ A.) by Zakharin in the eclipse of June 19, 1936

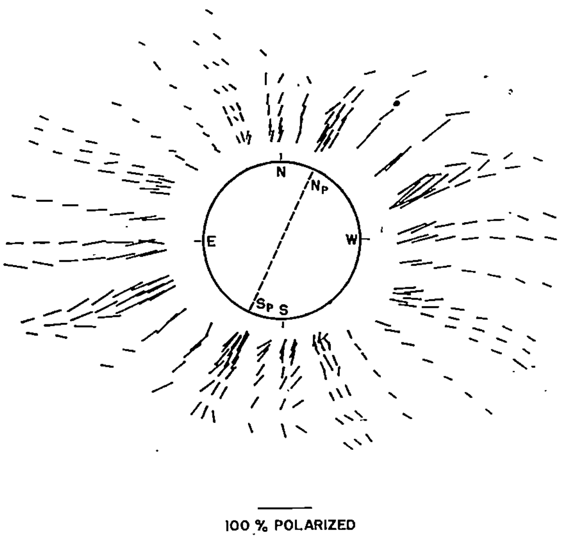

Fig. 3. Plot of the polarization magnitudes and directions obtained by Vashehakidse in the eclipse of September 21, 1941

The first measurement of the direction of the polarization was made by K. G. Zakharin during the eclipse of June 19, 1936[6]. His results are summarized in a table giving magnitudes and directions of polarization in two colours of visible light. These measurements have been plotted in Fig. 2, in which are shown the direction and magnitude of polarization as a function of position around the Sun. If these measurements are, in fact, correct, two remarkable effects are evident. One is the very great deviation from radial polarization, in some directions almost 90°; and the other is the almost complete absence of polarization in other directions. Both these facts could be understood if, in addition to radial polarization due to Thomson-scattering by the trapped particles, there is synchrotron radiation polarized in some other direction. For example, when zero polarization occurred one might assume that the synchrotron radiation gave polarized light perpendicular to the radius vector in approximately equal intensity to that due to Thomson-scattering with a radial polarization. Where the polarization is at almost 90° to the radius vector, one must assume that the overwhelming source of polarized light would be synchrotron radiation. It should be pointed out that high intensity of polarized light due to synchrotron radiation in the visible region requires electrons with kinetic energies of one to ten thousand million electron volts. However, the observations seem to indicate that such polarizations do exist.

The second measurement of polarization with three directions of the analyser was made by Richtmyer during the 1939 eclipse, but unfortunately Prof. Richtmyer died before he could study his plates. These plates are reproduced in various places[7] and have been studied by M. Schmitt[8]. Schmitt measured the polarization along several streamers which were evident in Richtmyer's pictures and found that in the case of one of these streamers the direction of polarization deviated from radial by 30°.

The third measurement of polarization to which we refer was made by Vashehakidse[9] during the eclipse of 1941. The result of plotting these measurements is shown in Fig. 3. It appears here that although there is a lack of radial polarization, the extent of this deviation is not nearly as great as that observed by Zakharin. It should be pointed out, however, that in this eclipse the total light emitted from the corona was only half that observed in the 1939 eclipse, and there may have been fewer particles injected which were capable of producing synchrotron radiation.

The fourth measurement, that of K. Saito, is not available to us.

We believe that very careful measurements of the direction of polarization, especially in the infra-red, would be a crucial test of the presence of synchrotron radiation in the corona. In the infra-red the intensity of the Thomson-scattered light should be reduced and the intensity of the synchrotron radiation increased.

(*B*) *Changes of the corona with the sunspot cycle.* It is well known that the shape and intensity of the solar corona are greatly dependent on the sunspot cycle. At sunspot maximum the corona seems to be almost spherical and approximately twice as bright as the sunspot minimum corona, which is extended in the equatorial plane. Such changes, although difficult to understand in the gravitation equilibrium model, could certainly be explained qualitatively by the injection and acceleration at sunspot maximum of larger numbers of particles in the trapping field. It will be interesting to see whether fluctuations of the solar cycle occur in the Van Allen radiation around the Earth to the same extent that they appear to occur in the solar corona.

(*C*) *Infra-red excess.* A number of authors[10] have measured the ratio of total radiation to visible for the corona and the Sun itself. These measurements are generally in agreement that the coronal emission is rich in infra-red, relative to the Sun.

The explanation of the coronal light as due to Thomson-scattering of sunlight is unable to account for this phenomenon. On the other hand, the presence of synchrotron radiation almost certainly implies that at longer wave-lengths the corona should become brighter. It is worth noting that the infra-red excess in the 1936 eclipse in which Zakharin's polarization measurements were obtained was approximately 4 to 1 relative to the Sun[11]. In other words, the corona had relatively four times more non-visible light than did the solar spectrum. In the corona of the 1941 eclipse, in which smaller deviations from radial polarization were observed, the infra-red excess was also reduced[12].

The strengths of the solar magnetic fields required by our model are determined by the properties of the synchrotron radiation. Unfortunately, the determination of B depends not only on the intensity of synchrotron radiation but also on the energy spectrum of the trapped particles.

If one knew the spectral properties as well as the intensity of the synchrotron radiation one could determine both the energy spectrum of the trapped particles and the strength of the trapping fields. We can, however, make some estimates assuming the following :

(1) The synchrotron radiation is equal in intensity to the Thomson-scattered light in the visible region. This leads to equation 1 :

$$B^2\gamma^2F = 50 \qquad (1)$$

(2) The critical frequency, or frequency of maximum emission, of the synchrotron radiation corresponds to the wave-length of red light. This condition is represented by equation 2 :

$$\gamma^2B = 3\times10^7 \qquad (2)$$

In our equations B is magnetic field in gauss ; γ is the ratio of electron energy to rest mass energy ; and F is the fraction of the electrons which have energy γ mc.^{2}. We have also computed T, the lifetime for energy loss by radiation, and R, the ratio of the energy density of the radiating electrons to $B^2/8\pi$. This latter quantity should not exceed 1. The equations for T and R are :

$$T_{(\text{sec.})} = \frac{5\times10^8}{\gamma B^2} \qquad (3)$$

$$R = 1{,}000\,\frac{F}{B^2}\,\gamma \qquad (4)$$

In Table 1 are the results of these calculations for γ's of 10^2 to 10^4. A γ of 10^2 is ruled out because it leads to an unreasonable value of B ; a γ of 10^4 is ruled out because the energy density is too high for containment in the field. Values of γ near 10^3 lead to reasonable estimates of F, B and R.

Table 1

γ	F	B	T	R
10^2	5×10^{-10}	3,000 gauss	0·5 sec.	5×10^{-12}
10^3	5×10^{-8}	30 gauss	500 sec.	5×10^{-5}
4×10^3	10^{-6}	2 gauss	3×10^4 sec.	0·5
10^4	5×10^{-6}	0·3 gauss	5×10^5 sec.	500

In order to check the hypothesis suggested above, precise measurements of the polarization over a wide spectral range, as well as of the spectral composition of the light, will be important. We are now planning to carry out such measurements during the eclipse of October 2, 1959. In addition to studying the polarization and quality of the spectrum, we hope to be able to determine whether the solar corona has an intensity maximum close to the Sun similar to that observed at larger distances in the Van Allen radiation. Our measurements will be made with a television-type scanning scheme using photomultipliers. The problem of reversal in photographic emulsions has previously masked the possible presence of a maximum. It would seem reasonable that if such a maximum exists it would have to occur close to the Sun, since the injection into the solar trapping field is from the inside, whereas in the case of the Van Allen radiation around the Earth the injection probably takes place from the outside. The basic similarity of the two phenomena, however, suggests, perhaps, that the Van Allen radiation belt could be called the corona of the Earth.

We wish to thank Prof. J. R. Winckler for stimulating and helpful discussions.

NEWS and VIEWS

Electrical Engineering at Saskatchewan:

Prof. W. E. Lovell

Prof. W. Edward Lovell, who will retire as head of the Department of Electrical Engineering in the University of Saskatchewan, Saskatoon, on June 30, 1960, graduated at the University of Manitoba. He joined the staff of the University of Saskatchewan as a lecturer in 1923, and was appointed professor and head of the Department of Electrical Engineering in 1924. Prof. Lovell has been closely concerned with problems of electric power generation and distribution in the prairie provinces of Canada. He has been widely acclaimed as an outstanding teacher in the field of electric power production, and he has been responsible for introducing many innovations in the undergraduate laboratories.

Prof. Lovell was president of the Association of Professional Engineers of Saskatchewan in 1937, and has been chairman of the Saskatoon Community Planning Commission since 1940. He was a member of the Street Railway Commission in 1932.

Prof. N. F. Moody

Mr. N. F. Moody, head of the Basic Circuit Research Division of the Canadian Defence Research Board, Ottawa, has been appointed professor of electrical engineering in the University of Saskatchewan, Saskatoon, from July 1, 1959.

The Editors regret that, due to difficulties in the printing industry, some sections of this issue of "Nature" have had to be curtailed

During the Second World War, he was at the Telecommunications Research Establishment, Malvern, and, in collaboration with Prof. F. C. Williams, he worked on various aspects of radar research, including automatic range gates, guidance of aircraft by means of radar techniques, and aircraft blind-landing systems. Mr. Moody was head of the Electronics Branch of the National Research Council Atomic Energy Project at Chalk River, Canada, during 1947–51. In 1951 he was appointed superintendent of electronics in the High Explosive Research Establishment of the Ministry of Supply, Fort Halstead, and he was responsible for the elaborate telemetering equipment used in the tests of the first British atomic bomb. Mr. Moody returned to Canada in 1953 and became the first head of the Basic Circuit Research Division at the Defence Research Board, Ottawa.

During the past six years he has established one of the leading laboratories in Canada for the study of semi-conductor devices, and his personal contributions in the field of ultra-high-speed transistor circuits have been notable. Prof. Moody will be associated at Saskatoon with Prof. Arthur Porter, who left the Imperial College of Science and Technology in 1958 to become dean of engineering at the University of Saskatchewan (see *Nature*, 181, 1178; 1958).

Space Research in Britain

In replying to further questions in the House of Commons on April 27 regarding space research, the Minister of Supply, Mr. A. Jones, declined to add to his previous statement (see *Nature*, May 2, p. 1231) and asked members to await the promised statement of policy. Nevertheless, the Parliamentary Secretary to the Ministry of Supply, Mr. W. J. Taylor, welcomed an adjournment debate on this subject on April 29 and outlined briefly what Britain had already done in this field, assuring Mr. de Freitas, who opened the debate, that the Government is giving active consideration to the question of Britain engaging in an Earth satellite programme. British activity in this field began to take shape in the autumn of 1953, when the Royal Society considered the value and practicability of research into the upper atmosphere, extending roughly to about 150 miles from the Earth's surface. In April 1955 five university groups started experimental work and they have since been joined by a sixth. The Royal Aircraft Establishment undertook to develop rocket vehicles suitable for these experiments and, by agreement with the Australian Department of Supply, arrangements were made for the rockets to be launched at Woomera. The first trial flight of the rocket developed for this purpose, *Skylark*, took place early in 1957, and a series of twelve fully instrumented firings began in the spring of 1958.

Mr. Taylor stressed the magnitude of Britain's effort in tracking the Earth satellites launched by the Americans and the Russians and in analysing the data received from them, referring to the international recognition of the very fine work of the Department of Scientific and Industrial Research stations at Slough and Singapore, the Jodrell Bank radio-telescope and of some Ministry of Supply establishments. New information had been obtained about the shape of the Earth and a contribution made to the study of air-drag on satellites and its interpretation in terms of air density. While, however, the Government is considering the possible use of the *Black Knight* research vehicle and the *Blue Streak* ballistic vehicle in an Earth satellite programme, it could not allow any such use to interfere with the place *Blue Streak* took in the military programme of deterrence. It had sought the considered views of the best scientific opinion in Britain, and Mr. Taylor repeated that an announcement as to whether and in what way the United Kingdom should extend its research activities into outer space would be made very shortly. Replying to specific points raised by Mr. de Freitas, Mr. Taylor thought that Mr. de Freitas's estimate of £10 million to £20 million as the cost of a satellite research programme over the next five years might be too modest; further design studies would be needed before reliable estimates could be made. He welcomed, however, the suggestion that the satellites should be designed as laboratories in space, working in a definite scientific field, but he did not think that a satellite programme was so crucially important that the scientific well-being of the country stood or fell by it. He also thought that the dangers of scientific emigration should not be exaggerated, nor the effect on it of any decision regarding space research. There was, and would continue to be, great scope for international co-operation outside the Commonwealth in this field, and Mr. Taylor referred particularly to the International Committee on Space Research, one of the fruits of the International Geophysical Year. It was also expected that an *ad hoc* committee of the United Nations could meet shortly to consider what international action regarding co-operation in the peaceful uses of outer space could profitably be taken at inter-government level.

Manchester Literary and Philosophical Society: New Building

THE foundation stone of the new building of the Manchester Literary and Philosophical Society was laid at 36 George Street—the site of the old building destroyed in an air raid in December 1940—by the Lord Mayor of Manchester, Alderman J. E. Fitzsimmons, on April 30, and it is expected that the new meeting house will be ready in about a year's time. In welcoming the Lord Mayor, the president of the Society, Mr. C. E. Young, said that the building destroyed in 1940 had housed the Society for at least 140 years. Before the building was acquired in 1799 the Society, which was founded in 1781, had met first in the Assembly Coffee House, which was probably in the Exchange Buildings of that day, and later in a room at the back of Cross Street Chapel. Mr. Young referred to the association with the Society of such famous scientists as Percival, Dalton, Joule, Schunck and Roscoe, among its past presidents, and afterwards, in a speech at an informal luncheon, expressed the hope that the Society would become a meeting place of minds from town, university and industry, representing and serving the everyday intellectual life of the city.

Thanking the Lord Mayor on behalf of the Society, Lord James expressed the conviction that there is even more important work for such a Society to do to-day. When it was founded and for the next half-century, an educated man could take all knowledge for his province. That is no longer possible, and one of our greatest needs is to encourage communication between men educated in different fields. Lord James thought the Literary and Philosophical Society could make a very important contribution to the establishment of channels of communication between specialists. By providing a formal and informal meeting place for people with widely differing interests, the Society was preparing to maintain and extend its original task of stimulating the intellectual life of the city. That task would call for the support and encouragement, financial and otherwise, of a considerable body of sympathizers. Mr. Young referred particularly to the need for adequate financial support for operation and maintenance, although the membership of the Society is now 320, the highest in its history. Virtually all the contents of the old centre were destroyed by fire, including the records, the library and Dalton's manuscripts and other relics, and there is a deficit of some £10,000 on the £35,000 which the new building will cost, to be met before the Society can be re-established on a sound financial footing. It is hoped and expected that the lecture rooms will be used by many of the numerous scientific and other societies which are active in Manchester. Both Mr. Young and Lord James paid tribute to the work of the Society's honorary treasurer, Mr. H. Hayhurst, in promoting the scheme.

The Vienna Declaration and Nuclear Disarmament

THE Vienna Declaration, adopted by the participants in the Third Pugwash Conference held at Kitzbuhel, Austria, on September 14–19 and at Vienna on September 20, 1958 (cf. *Nature*, 180, 358; 1957), has been sent, with a questionnaire and a letter signed by Lord Russell, to scientists all over the world to ascertain whether there is general support for the ideas expressed in the Declaration and for further activities based on it. The Declaration affirms that the only restraint against the use of nuclear weapons in war would be agreements not to use them, which were concluded in time of peace: the possession of such weapons is relatively unimportant, as in any future major war each belligerent would feel compelled to undertake immediate production of nuclear weapons, and for a major industrial power less than one year should suffice. The statement recognizes that any agreement on disarmament, and particularly on nuclear disarmament, requires a measure of control to protect every party from possible evasion, and because of the technical difficulties, the need for policies encouraging international trust and reducing mutual apprehension is stressed. The signatories believe that, as scientists, they have an important contribution to make towards establishing trust and co-operation among the nations, and that science can best serve man if it is free from interference by any dogma imposed from outside, and can exercise its right to question all postulates, including its own. The scientific tradition of mutual understanding and of international co-operation can, and should be, extended to many fields of technology.

Quality of Protein Feeding-Stuffs

SIR SOLLY ZUCKERMAN, a member of the Agricultural Research Council and chairman of its Protein Quality Group, writes: The Agricultural Research Council has organized a collaborative investigation into the measurement of the quality of protein feeding-stuffs. Several centres are taking part in a trial designed to establish whether any rapid laboratory tests can give a reliable indication of the feeding value of such materials. Specimens of these materials, some of which have been imported, were kindly supplied by manufacturers who have included, in response to a request to cover as wide a span of quality as possible, samples known to be bad, as well as samples within the commercial range. When it has been completed, the results of the whole trial will be published by the Committees as a whole. In the meantime, however, it is probable that members of the staff of the participating laboratories will be publishing in various journals papers describing work in which some of these samples have been used, but which deal with matters not directly related to the correlations which the joint effort is designed to elucidate. It has been agreed that in any such papers the samples used will be described by the code numbers uniformly used by the whole group.

Australian and New Zealand Association for the Advancement of Science

A REPORT on the future of the Australian and New Zealand Association for the Advancement of Science published in the *Australian Journal of Science* for October 21, 1958, advocates discontinuing the Handbook and Report and making greater use of the *Australian Journal of Science*, which it is proposed to publish monthly. Conferences every year and a half are recommended instead of annually or biennially, but no change in the names or number of the Sections are recommended apart from the formation of a new Section corresponding with the Assembly of Corresponding Societies in the British Association. Stress is laid on keeping the public informed on what science is doing as the primary function of the Association and the report recommends that as much sectional time as possible should be devoted to meetings of the symposium type which present more general matters from several angles.

Journal of Medicinal and Pharmaceutical Chemistry

THIS new journal (1, No. 1, February 1959. Pp. 120. Published bi-monthly; subscription price 115*s.* or 15 dollars per annual volume including postage. New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959) will be mainly of interest to the synthetic chemist engaged in the manufacture of drugs and to pharmaceutical chemists and pharmacologists whose line of research lies in the drug-action relationship. "Chemical-biological correlative work" is defined by the editors as one of the main fields which the new journal wishes to cover. Papers are to be accepted in English, French or German. The increasing number of drugs produced by the chemical industry, all of which need biological evaluation, probably created a need for a special journal to deal with the quantity of work done; the future will show whether this need could not have been covered by the existing journals.

Commonwealth Bursaries Scheme

THE fifth annual report on the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme covers the year ended December 31, 1958 (pp. 8. London: Royal Society and Nuffield Foundation, 1959), in which 26 bursaries, totalling £13,974, were offered, compared with 18, totalling £8,423, in 1957. Of these 8 were for visits from the United Kingdom, 12 for visits to the United Kingdom and 3 for visits between countries of the Commonwealth other than the United Kingdom; three offers were not accepted. Of the 67 applications considered during the year, 44 were for visits to the United Kingdom, 11 for visits from the United Kingdom and 12 for visits between Commonwealth countries other than the United Kingdom. Most of the applications were of a high standard. Besides the Nuffield Foundation's grant of £5,000, which was received for 5 years from 1959, £2,000 was received through a Parliamentary Grant-in-aid to the Royal Society, £1,200 from Canada, £800 from Australia, £400 from South Africa, £322 10s. from Pakistan, £200 from New Zealand, and £100 each from Ceylon, Rhodesia and Nyasaland.

Studies in Indonesia

THE Jajasan Siswa Lokantara, the local Indonesian foundation for granting fellowships to foreigners studying in the country, is ready to consider suitably qualified applicants in any subject of study. This foundation has considerable funds at its disposal and is independent of government departments; it is prepared to guarantee all reasonable local expenses, including living costs and fares within Indonesia, but owing to the considerable variations in cost of living throughout the territory has refrained from fixing a definite monthly allowance. The intention is to operate a flexible and reasonably generous allowance scheme which will enable Fellows to study where they wish (so far as internal conditions and transport facilities allow), and to establish close relations with Indonesians working in similar fields. Further information can be obtained from the Universities Section, Education Division, British Council, 65 Davies Street, London, W.1.

First All-India Congress of Zoology

THE first All-India Congress of Zoology, sponsored by the Zoological Society of India, which was to have been held last year but was postponed, will be held at Jabalpur during October 24–29, at the invitation of the University of Jabalpur. Further information can be obtained from the General Secretary, Dr. B. S. Chauhan, c/o Zoological Survey of India, 34 Chittaranjan Avenue, Calcutta 12.

Announcements

DR. A. A. MOSS has been appointed deputy keeper of the Department of Mineralogy in the British Museum (Natural History).

PROF. JOHN READ, professor of chemistry in the University of St. Andrews, has been selected for the 1959 Dexter Award which is administered by the Division of History of Chemistry of the American Chemical Society.

DR. H. ALBERT BARKER, professor of microbial biochemistry in the University of California, Berkeley, has been awarded the Neuberg Medal for outstanding work in biochemistry and, in particular, for his discovery of the coenzyme corresponding to vitamin B_{12}. The Neuberg Medal was created to honour Carl Neuberg, a pioneer in biochemistry. It is given annually by the American Society of European Chemists for outstanding contributions in the field of biochemistry.

AN International Congress on Radiology will be held in Munich during July 23–30. Further information can be obtained from the Congress-Sekretariat, Reitmorstrasse 29, Munich 22.

A SYMPOSIUM on Fluorine Chemistry is being arranged under the auspices of the Chemical Society, to be held in the University of Birmingham during July 15–17, covering topics in organic, inorganic and physical chemistry. Further details can be obtained from the Secretary, Fluorine Symposium, Chemistry Department, The University, Edgbaston, Birmingham 15.

THE twenty-first International Congress of Physiological Sciences (Physiology and Pharmacology) will be held in Buenos Aires during August 9–15 under the presidency of Prof. Bernardo A. Houssay. Further information can be obtained from the Secretary, Twenty-first International Congress of Physiological Sciences, Facultad de Ciencias Médicas, Paraguay 2151, Buenos Aires, Argentina.

THE Gordon Research Conferences for 1959 will be held during June 15–September 4 at Colby Junior College, New London, New Hampshire; New Hampton School, New Hampton, New Hampshire; and Kimball Union Academy, Meriden, New Hampshire. The conferences were established to stimulate research in universities, research foundations and industrial laboratories. This purpose is achieved by an informal type of meeting consisting of scheduled lectures and discussion groups. Further information can be obtained from W. George Parks, Director, Department of Chemistry, University of Rhode Island, Kingston, Rhode Island; after June 15 from Colby Junior College, New London, New Hampshire.

INLAND WATERWAYS IN BRITAIN

THE debate in the House of Lords on February 17 on a motion of Lord Ammon's directing attention to the report of the Bowes Committee of Inquiry into Inland Waterways preceded by a few days the publication of the Government proposals in a White Paper (Cmnd. 676). The debate, nevertheless, was welcomed by the Earl of Gosford, who, in replying on the debate for the Government, said that the various suggestions made will receive careful consideration. Lord Gosford pointed out that the main points in the Committee's report were that capital development should continue to be concentrated on the 300 or 400 miles of the more than 2,000 miles of inland waterways in Great Britain which carry busy and remunerative traffic. Another 900 miles carry some commercial traffic but are unremunerative, and the Committee recommends the rehabilitation to navigation of these waterways with the development of other uses and revenue. The remaining waterways have outlived their commercial utility and the Committee proposes a case-by-case review to assess their possibilities and prepare schemes for future treatment.

Lord Gosford indicated that the Government was fully aware of the many interests concerned in these proposals, including water undertakings, drainage and river boards, farmers, anglers, naturalists and amenity, but his reply foreshadowed the Government's proposals in the White Paper. They cover an interim policy over about two years in which some of the Committee's ideas can be tried out experimentally, but while endorsing the Committee's objectives in redevelopment and proposing to set up an Inland Waterways Redevelopment Advisory Committee, and accepting that legislation to facilitate redevelopment is needed, the Government is not prepared at present to commit itself to the detailed procedural machinery suggested. It also considers that the cost of redevelopment should be borne by those who benefit from it.

The Nature Conservancy in its last annual report expressed the view that the findings and recommendations of the Bowes Committee providing for the setting up of a waterways redevelopment board to prepare schemes for redevelopment, but envisaging the participation as new owners of river boards or drainage authorities, water undertakings or local authorities, and, exceptionally, special trusts, are regarded as meeting adequately the Conservancy's needs. Lord Gosford, however, did not refer to the boards, although this question was specifically raised by Lord Latham in the debate. In the White Paper the Government accepts the view that proposals for costly schemes of improvement are not justified in present circumstances and that instead there should be a gradual extension of the work which has already been carried out. The Committee recommended that the Great Yarmouth Port and Haven Commissioners should be reconstituted on a wider basis of membership and with greater powers, and the Nature Conservancy appears to accept this view. Nevertheless, and although the Committee also urged that the demand now for the use and development of the rivers and Broads was greater than ever and their deterioration could be stayed and improvement ensured by a revision in the powers of the Commissioners and a small increase in their income, the Government is not prepared to introduce the recommended legislation without first thoroughly exploring the administrative proposals between the various interests concerned. Discussions between representatives, however, have already begun, including those of the National Parks Commission, although it may be noted that the Committee is not impressed by the arguments for making the Broads a national park.

THE NATIONAL OCEANOGRAPHIC COUNCIL

REPORT FOR 1957–58

THE annual report of the National Oceanographic Council for 1957–58* reviews progress in the two main fields of work of the National Institute of Oceanography: marine physics and marine biology. With a staff of eighty-four (not counting officers and crew of R.R.S. *Discovery II*) and with an annual expenditure of £201,000 mainly met by United Kingdom and Commonwealth Government grants, the effort has been chiefly devoted to studies of the interaction between atmosphere and ocean, water movement on large and small scales, biological fertility of the oceans, and the distribution of marine animals. Basic knowledge of physical and biological processes has also been applied to practical problems.

R.R.S. *Discovery II* spent two periods of nearly three months measuring currents in the Gulf Stream and working stations across the Atlantic in latitudes 48°, 32° and 24° N., as part of the Institute's contribution to the International Geophysical Year. A large part of the fuel was kindly provided by the Woods Hole Oceanographic Institution, and United States oceanographers and vessels collaborated in this international attack on the problems of ocean circulation. Deep-water isohalines, computed from the electrical conductivity of samples taken at a range of depths at stations about 8 miles apart, revealed greater irregularities in water properties and motion than had been inferred from earlier, less-precise observations.

The technique of tracking deep currents by means of neutrally buoyant floats, pioneered at the Institute, has stimulated similar measurements elsewhere, as well as theoretical studies of ocean circulation. Floats have now been made which will send out signals for a few hours each day for a month. The more practical needs of the fisherman and the fisheries scientist for a knowledge of sub-surface currents has also been met by improvements in a simple but ingenious method of recording the orientation and inclination of a container moored in the current. Echo soundings made along 12,000 miles of the ship's track have included detailed surveys of the Porcupine Bank (from which rocks were collected) and large sand waves on the continental shelf to the west of the English Channel which attain 40 ft. in height and 3,000 ft. between crests.

---

* Annual Report of the National Oceanographic Council, 1 April, 1957–31 March, 1958. Pp. v+39. (Cambridge: At the University Press, 1958.) 5s. net.

Research on processes operating at the sea surface, in particular wind waves, has been mainly directed at finding a convenient way of measuring the directional distribution of wave energy and to the development of an adequate physical theory relating the wave spectrum to wind, stability, and other factors governing turbulent shear and the exchange of energy between atmosphere and ocean. Theoretical studies of the curvature of random surfaces and the distribution of intervals between 'crests' of random functions enable directional information to be derived from aerial photographs of waves. Other theoretical studies of far-reaching practical significance have been concerned with the estimation of the mean wave energy from the highest waves in a record; with the accuracy of wave measurements using accelerometers in buoys or ships; with the vertical components of motion of a ship heading into sea waves; with the relative merits of empirical formulæ for wave and swell prediction; and with long waves and storm surges. Tidal records initiated by the Institute at Stornoway and Lerwick support the theoretical conclusion that surges arriving from the Atlantic are amplified on passing down the east coast and suggest that large surges are most likely when intense storm depressions travel from the south-west for a long distance along the continental shelf.

The Institute is still the chief protagonist of the wave-interference theory of microseism generation. While there is still need for clarification, it has proved possible to track isolated storms in the North Atlantic by analysis of microseism activity at Kew. There is a practical application in tracking storms and giving warning of heavy swell on coasts facing oceans that have little meteorological cover. An electronic seismograph has been constructed which allows exceptional magnification in the 3–10-sec. range. Other instruments in the course of development include an airborne radar sea-swell recorder and a pressure recorder of high precision which, when used to record waves, can be calibrated by tidal observations.

The Institute's biological work falls into three broad groups: the distribution and taxonomy of marine animals, particularly oceanic plankton, based to a large extent on the *Discovery* collections; the bionomics of whales; and the productivity of oceanic waters. Objects of study last year included: the alcyonarians (revision of the pennatularian genus *Umbellula*); certain families of the isopods (fifteen species, of which five and one family are new); deep-living chaetognaths (including a new species with a method of fertilization hitherto unknown in this group); the distribution and life-cycles of the Antarctic copepod *Calanoides acutus* and of the euphausid *Euphausia triacantha*.

During a spring cruise to the Canary Islands, additions were made to the collection of photographs of oceanic animals, ranging from small planktonic forms to moderately large cephalopods, including a dramatic sequence at 500 m. in which a squid was attacked and eaten by another squid. Observations on the composition and numbers of phytoplankton and zooplankton, compared with those made in the same waters on previous cruises, emphasized the remarkable stability and constancy of the crops in this part of the open ocean in different years. During this and other cruises, particular attention has been paid to the factors controlling rates of assimilation of carbon in regions of dense and sparse phytoplankton, and to the significance of the ratios of chlorophyll *a* and *c* in coastal and oceanic regions.

Largely through the help of whaling inspectors and companies the Institute has been able to examine ear plugs and ovaries from several hundred whales. Ear plug laminations and the corpora albicantia in the ovaries are indices of age and provide valuable evidence on life-histories, rates of ovulation, and on year-to-year changes in the stock. Recovery of whale marks has consolidated and extended earlier inferences about distribution, migrations, and interchange between the south-west Atlantic and south-east Pacific in both directions.

Finally, it is encouraging to record that governmental aid has been increased to allow for expansion of staff, that four investigators from overseas have played a considerable part in the work, and that the effort devoted to the problem of fish detection is welcome evidence of increasing collaboration between the physicists and the biologists.

C. H. MORTIMER

THE ROCKEFELLER FOUNDATION

REPORT FOR 1957

THE annual report of the Rockefeller Foundation for 1957, in which appropriations totalled 42,798,916 dollars, including 8,298,260 dollars for medical education and public health, 5,255,235 dollars for biological and medical research, 5,621,400 dollars for the agricultural programme, 3,570,525 dollars for the social sciences and 5 million dollars to the American University of Beirut, stresses the broadening basis of co-operation among governments, with which the work of the Foundation has brought it into close contact at the local level in every continent. For half a century the Rockefeller boards have been intimately involved in the international community of science and scholarship, particularly in the financial support of scholarship and science abroad, largely through the universities, but using various techniques. Special emphasis is laid on the value of the Foundation's fellowship programme, under which 7,432 men and women from 98 countries, including 1,306 from the United States, have held fellowships for advanced study in 80 countries: of these, 248 received awards in 1957, when 532 persons from 53 countries pursued their training or research in 104 institutions in 20 countries.

Discussing the characteristics of this international community of science and scholarship, the report emphasizes that it is open to all who wish to contribute ideas and its respect is bestowed on the basis of merit, not of authority. Sweeping beyond national frontiers, the community is linked by a strong network of communication through books, scientific and learned periodicals, meetings, and a persuasive flow of travel and personal correspondence, in which much has been done to remove the barrier of language. Development now involves the fullest participation in this community of science and scholarship and it is suggested accordingly that present tensions underline the need to seek out and cherish those elements of modern life which bind men together across national and cultural frontiers. In the United States alone 66,000 persons participated in educational exchange during the year, 52,000 from 145 countries or territories coming to study or teach, and 14,000 Americans visiting 50 countries for similar tasks. Secondly, governments have demonstrated their ability to set political issues aside at selected points to co-operate effectively for the welfare of their peoples, and if international politics has not yet found practicable means for settling disputes, the field of politics could be reduced by steadily broadening the basis of co-operation on the long-range humane interests of man.

The President's review selects for emphasis the Polish science programme on which in May 1957, following a visit of Foundation representatives to Poland, grants of 300,000 dollars for purchase of scientific materials and supplies, books and periodicals and of 175,000 dollars for fellowships for younger Polish scientists to visit other countries were made. The new grants for Poland are concentrated on medical education, public health, the biological and medical sciences and agriculture, as the Ford Foundation, also at the invitation of the Polish Government, has initiated a programme in social sciences and humanities. Of the 25 fellowships awarded, 19 have already commenced study, most in the United States, but 4 in the United Kingdom, and grants-in-aid were also made to 21 more mature Polish scientists.

In referring again to the public health aspects of nuclear energy, the report suggests that the complicated and difficult problems which will accompany massive use of nuclear energy involve special responsibilities for the universities; the Foundation is accordingly supporting several broad programmes of special advanced training. That at the New York University Institute of Industrial Medicine stresses the chemical and radiobiological toxicological problems of the nuclear energy industry, particularly quantitative aspects of environmental contamination; at Harvard and at Pittsburgh problems of air-borne chemical and radiobiological contamination are stressed, while at Johns Hopkins University the primary emphasis is in the expanded Department of Biophysics: each of these institutions is receiving 500,000 dollars.

Dealing with the Foundation's operating programmes, the President reviews in some detail its world-wide study of the virus infections transmitted to men and domestic animals by the bite of arthropods. Under it more than 70 distinct viruses have been discovered, 37 of which have been shown to be members of one or other of three immunologically related families, 27 being located in South America, 24 in the Ethiopian region and 15 in the Oriental region, including India, Malaya, the Indonesian Archipelago, Indo-China and South China. He refers to the rapidity with which, in 1957, following the discovery in India of an agent belonging to the Russian tick-borne complex of viruses, the etiology of the disease and its major epidemiological features were elucidated. This shows the utility of the Rockefeller Foundation's virus programme. A special appropriation of 100,000 dollars will assist the Indian Government with its vaccination campaign and enable Indian scientists to study vaccine production techniques in the United States.

Under the agricultural programme, now in its seventeenth year, the Mexican, Columbian, Chilean and Indian agricultural programmes, the last differing from the others in including direct connexion with a graduate school of agriculture and the correlation of the food crop research projects with the research and training activities of the school, will receive support. The Mexican and Columbian programmes have participated in the National Research Council project for preserving indigenous varieties of corn by systematically collecting samples of every extant variety in the High Andean region, Central America and Mexico, while all three Latin American units are co-operating in the international wheat rust nursery of the United States Department of Agriculture.

THE PLANT BREEDING STATION, NJORO, KENYA

By H. C. THORPE

Department of Agriculture, Kenya

THE new research laboratories of the Plant Breeding Station, Njoro, were opened on August 29, 1958, by the Speaker of the Kenya Legislative Council, Sir Ferdinand Cavendish-Bentinck. He was deputizing for the Minister of Agriculture, the Hon. Michael Blundell, who was unable to be present owing to illness. The ceremony was held in the presence of representatives of agricultural and milling interests, and of a large gathering of farmers from all over the country. After the opening, visitors were shown the field work in progress and conducted through the new laboratories where exhibits had been arranged demonstrating the various problems under investigation.

The building was designed and built by the Ministry of Works, in consultation with the Department of Agriculture, to cater for the special needs of the plant breeding team. The east wing houses the threshing room and cereal-selection laboratory, with space for the storage of sheaf material and packeted seed; special features are the provision of adequate well-lit benching for grain selection, and the arrangement of the layout for ease and efficiency of handling the breeding material. The west wing houses the pathology section, which deals with cereal diseases with special reference to wheat stem rust. The main body of the building consists of the administrative offices, a cereal chemistry laboratory, library, dark room, stores and service rooms, as well as private rooms for individual research officers. Much thought has gone into the planning of the layout, and the architect has designed a light and airy building of pleasing character, yet retaining its strictly functional purpose, for a total cost of £15,000.

The Station is situated at 7,100 ft. in the Kenya Highlands, virtually on the equator, in one of the main wheat-growing areas of the country. It is the headquarters of the Plant Breeding Section, and the main programme on wheat, barley and oats is concentrated there. The present staff of the section, including two plant breeders working on maize at subsidiary stations, comprises eight graduate officers and additional supporting staff.

History records that the early settlers in Kenya started growing wheat at the beginning of the century; but that they suffered great loss due to rust attacks. Although a certain amount of desultory work was carried out from 1910 onwards, it was not until 1928 that wheat-breeding was put on an organized basis as a result of the visit of the late Sir Rowland Biffen, and the advice he gave to the Government to set up a wheat-breeding station. In that year the original station was built at Njoro and the late Capt. J. G. L. Burton, one of Biffen's pupils, was appointed to the first post of plant breeder. He was assisted by Mr. R. J. Lathbury, who later took charge when Burton retired. The Station has, until recently, remained virtually unchanged since those early days.

The present period of expansion dates from 1952–53 when development funds were first made available. The provision of improved facilities had become especially necessary due to the severe outbreaks of rust causing great damage to existing wheats and the urgent need to produce resistant varieties. The development has entailed recruitment of extra staff, purchase of additional land and specialized equipment, and now the construction of the new laboratories. It is especially satisfactory that farmers themselves, by agreeing to a cess on wheat, have made a substantial contribution to this development. Certain further projects, however, connected with rust pathology and maize breeding await the grant of special funds.

The plant breeding team is fortunate in being provided with such excellent new laboratories and modern facilities. Indeed, these are essential to the necessary intensification of the research programme to provide the rust-resistant wheats Kenya so urgently needs.

THE GALACTIC SYSTEM AS A SPIRAL NEBULA

THE view that the Galaxy might have a spiral structure has been expressed almost since the first discoveries of such structure in nebulæ. It was not until 1951, however, that part of the galactic spiral structure was actually found. Work in this field has recently been summarized in a report on the progress of astronomy by J. H. Oort, F. T. Kerr and G. Westerhout (*Mon. Not. Roy. Astro. Soc.*, 118, 379; 1958). The first definite discovery of spiral structure was accomplished by W. W. Morgan, S. Sharpless and D. E. Osterbrock, using the luminosity criteria for *O* and *B* stars developed by Morgan. They determined the distances of groups of these stars, and they showed that the regions of ionized hydrogen excited by the stars were arranged in long chains which formed parts of spiral arms. By a remarkable coincidence, radiation on 21-cm. wave-length from interstellar hydrogen was detected at about the same time as the visual work was done, and by 1954 a comprehensive picture of the spiral structure of the Galaxy could be assembled from radio observations. The importance of hydrogen-line radiation at 21 cm. arises partly because of the transparency of interstellar dust to radio waves and partly because the study of this radio spectrum line gives discrimination in distance. Actual distances can only be inferred from radial velocities, and this involves the assumptions of circular motion and of equality of motions of stars and gas in any particular region of the Galaxy.

In order to transform radial velocities into distances, we must know how the circular velocity in the Galaxy varies with the distance from the galactic centre, and we must know the distance of the Sun from the centre. If we know the distance and circular velocity of the Sun we can derive, from the radio observations themselves, the variation of circular velocity with distance from the centre for distances smaller than that of the Sun. The distance from the Sun to the centre has been obtained directly from the study of the distribution of cluster-type cepheid variables concentrated near the centre. The best estimate obtained in this way is 8·2 kiloparsecs, the accuracy being limited by the uncertainty in the interstellar absorption and in the absolute magnitude of the variables. The circular velocity, and an independent estimate of the solar distance, can be obtained by combining radio observations with the constants of differential galactic rotation obtained from the proper motions and radial velocities of distant stars. The best available estimate of the circular velocity of the Sun is 215 km./sec. For regions of the Galaxy farther from the centre than the Sun we cannot determine the rotational velocities from radio observations, and we must rely on values computed from models of the Galaxy based on stellar densities. The rotation curve derived by M. Schmidt from all available data shows a maximum of about 225 km./sec. at a distance of 7 kiloparsecs from the centre.

From profiles of the 21-cm. line one can now derive the density distribution of the neutral hydrogen in the Galaxy. Most of the hydrogen is confined to a flat disk, with a half-density whole-width of 220 parsecs. This hydrogen disk is remarkably flat; nowhere within 8 kiloparsecs from the centre do the points of maximum hydrogen density deviate by more than 75 parsecs from the galactic plane, although there are rather larger deviations in the outermost parts of the Galaxy. In contrast to this arrangement about the galactic plane the distribution in the plane shows great irregularities. The hydrogen outlines the spiral arms of the Galaxy. The Sun is situated near the inner edge of one arm; the latter probably contains the Orion association, and the whole arm is now called the Orion arm. Outside this, at a distance from the galactic centre of between 10 and 12 kiloparsecs, there is a conspicuous arm, called the Perseus arm, which contains the double cluster in Perseus. Inside the Orion arm, between 6 and 7 kiloparsecs from the centre, there is the Sagittarius arm. The hydrogen disk appears to terminate at about 15 kiloparsecs from the centre. The maximum density of hydrogen in the spiral arms is about 2 atoms/cm.^{3}; between the arms the density may fall to less than 0·05 atoms/cm.^{3}. These results are all compatible with the classification of the Galaxy as a spiral nebula of Hubble's type *Sb*. It is estimated that about 2 per cent of the total mass of the Galaxy exists in the form of interstellar gas. In the central region there is an arm at a distance from the centre of 3 kiloparsecs. The arm passes between the Sun and the centre, and in addition to participating in galactic rotation, this arm appears to be expanding with a velocity of 53 km./sec. away from the centre. This arm can be seen in absorption against the source Sagittarius *A* situated at the galactic centre. The existence of this expanding arm (and of other smaller features which are expanding) renders the rotation curve quite uncertain near the galactic centre.

The astounding flatness of the galactic interstellar medium is of importance in connexion with the internal motions in the medium. It provides a measure of the average random motion of the interstellar clouds, and it indicates that there must have been a considerable exchange of momentum from the inner to the outer parts of the disk. A fundamental question is whether spiral structure is a problem of gas dynamics (and magnetic fields) or of stellar dynamics. There seems no doubt that the spiral structure of galaxies is closely related to their content of interstellar gas, and the latter may be a prerequisite for spiral structures to develop. Supergiants and other young stars are situated in the spiral arms; there is as yet little evidence relating to the distribution of older stars and gas. The Galaxy rotates in a period of about 200 million years, and the effects of differential galactic rotation would severely distort any existing arms. The arms must either be smoothed out and replaced within this time or be maintained by some unknown mechanism independently of galactic rotation. There are reasons for believing that interstellar magnetic fields must be involved in such a mechanism. Interstellar polarization of the light of distant stars indicates the presence of magnetic fields, in many cases along the spiral arms. Part of the continuous radio emission from the Galaxy is closely concentrated in the galactic plane, and must be connected with spiral structure; the radiation appears to be of non-thermal origin, and may originate in synchrotron radiation from electrons moving in interstellar magnetic fields. The existence of radio coronae of the Galaxy and of the Andromeda nebula also supports the idea of the importance of magnetic fields. Nevertheless, we are forced to the conclusion that we have made little progress towards understanding the origin of spiral structure. We have, however, a much-improved knowledge of what has to be explained.

R. H. GARSTANG

IODINE AND COPPER UPTAKE BY SOIL ORGANIC MATTER

By J. M. NORTHMORE

Scott Agricultural Laboratories, Department of Agriculture, Kenya

ALTHOUGH the soil organo-metallic complex concept of Bremner *et al.*[1] has been confirmed by the work of Beckwith[2], these workers do not specify the nature of the organic component of the complex. However, the relationship found between the replacement capacity of soil organic matter and its phenolic hydroxyl group content[3] points to material derived from lignin containing these groups being the organic component concerned. These considerations have led to an investigation of the relationships between the phenolic hydroxyl group content and the organo-metallic complex-forming capacity of the organic matter of a number of limed and unlimed soils from the Kenya Highlands. Wide ranges of *p*H values and organic matter contents were covered.

The phenolic hydroxyl group contents of the organic fractions of the soils were measured by the iodine uptakes according to the hypoiodite method of Norman and Peevy[4] as modified by Moodie[5]. The capacities of the same organic fractions to form organo-metallic complexes were measured by their copper uptakes by Lees's method[6] slightly modified.

Copper was taken as the complexing metal as it is known to have a greater ability to compete for sorption sites on organic matter than most of the other bivalent metals present in soil[2,7]. Preliminary investigations of the copper uptakes have indicated the possibility that added copper is preferentially absorbed by the organic fraction of a soil, and it is intended to offer evidence of this at a later date. Table 1 gives the copper and iodine uptake values obtained for the twelve soils studied.

The results show that increasing amounts of copper are taken up by the soil organic fractions with increasing *p*H values, the relationship between the two variables being curvilinear. No correlation

Table 1. IODINE AND COPPER UPTAKE BY SOIL ORGANIC MATTER

Soil	Total carbon (per cent)	Lime applied	*p*H	Copper uptake (m.equiv./gm. C)	Iodine uptake (m.equiv./gm. C)
*K*27	2·76	No lime	4·74	0·215	5·19
*K*20	2·86	4,400 lb./acre in 1953	5·16	0·268	4·55
*K*5	2·86	8,150 lb./acre in 1953	5·45	0·304	4·72
*K*48	2·53	17,740 lb./acre in 1953	6·12	0·735	4·35
*M*6	4·29	No lime	4·96	0·221	4·97
*M*8	4·22	15,000 lb./acre in 1954	6·01	0·628	4·76
MF	4·31	No lime	5·63	0·418	5·55

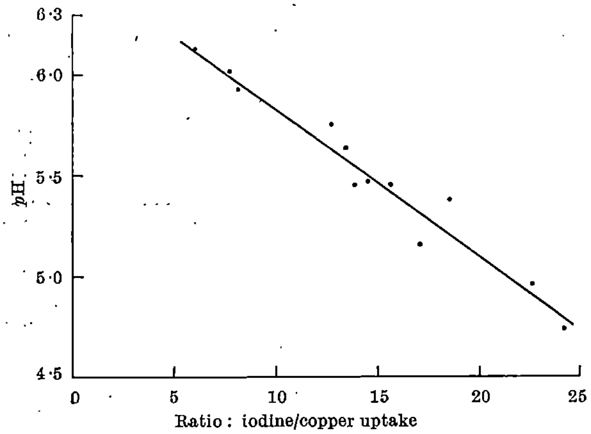

Fig. 1. Relation between pH and the ratio iodine/copper uptake by organic matter of some Kenya soils

is found between pH and iodine uptake. However, if the ratio iodine/copper uptake is plotted against pH then a rectilinear relationship results (Fig. 1), the regression equation of which is given by :

$$R = 90{\cdot}58 - 13{\cdot}85\, p\text{H} \quad (r = 0{\cdot}977)$$

A possible explanation of these results is suggested as follows.

It has long been thought probable that when the soil organic matter is treated with alkali, the compounds of high molecular weight undergo breakdown into smaller units, and it does not seem unreasonable to expect that at low concentrations of alkali the extent of this breakdown will depend upon the strength of alkali used.

If this effect can be extended to the action of lime in the field it might be expected that breakdown will occur with liming and the size of the organic structures existing in soil organic matter will be controlled by the pH of the soil. It has been shown that for the twelve Kenya soils studied, covering a fairly wide range of pH and total carbon values, a rectilinear relationship exists between pH and the ratio iodine/copper uptake. This relationship is taken as reflecting a close connexion between soil pH and the molecular complexity of its organic matter. The copper uptake, being determined at the pH of the soil, would be stoichiometrically proportional to the molecular compounds existing at that pH, and the iodine uptake, which is determined in the presence of 3 N sodium hydroxide solution, would be stoichiometrically proportional to the components of the compound. Therefore, the ratio of iodine/copper uptake would be a measure of the complexity of the molecular compound existing at that particular soil pH.

Evidence of the relationship between the copper- and the iodine-absorbing fractions of soil organic matter and the increase in copper absorption as compounds of high molecular weight are broken down into their constituent units when treated with alkali was obtained by treating four of the soils with concentrated ammonia. Excess ammonia was removed by drying followed by leaching with 0·5 M sodium sulphate solution. The copper uptake of the treated soil combined with the amount of copper required to precipitate the copper-precipitable constituents of the leachate was found to be much greater than the copper uptake of the untreated soil and to approximate to its iodine uptake (Table 2).

Table 2. Copper Uptake of Ammonia-treated Soil Organic Matter

Soil	Copper uptake untreated soil (m.equiv. Cu/gm. C)	Copper uptake of ammonia-treated soil (m.equiv. Cu/gm. C)	Iodine uptake (m.equiv. I/gm. C)
*K*5	0·304	4·72	4·72
*M*8	0·628	3·97	4·76
*ML*16	0·382	3·31	5·49
*K*48	0·735	5·06	4·35

The narrowing of the iodine/copper ratio with the increase of pH resulting from liming would appear to reflect a breaking down of soil organic complexes with parallel increase in mobility which may be of great importance in accounting for a number of the observed effects of liming.

STRUCTURE OF ANHYDROUS SODIUM SOAPS AT HIGH TEMPERATURES

By A. SKOULIOS and Dr. V. LUZZATI
Centre de Recherches sur les Macromolécules, 6 rue Boussingault, Strasbourg, France

THE present work is part of a systematic investigation of the liquid-crystalline structure of association colloids[1].

It is well known that anhydrous sodium soaps exhibit five liquid-crystalline allotropic phases at temperatures in the range 100–320° C. ; the transition points have been determined by different techniques[2], in particular, light transmission measurements, microscopic examinations under polarized light and dilatometric observations. The names of the phases and the transition temperatures are given in Table 1, taken from the paper by M. J. Vold, M. Macomber and R. D. Vold[3].

H. Nordsieck, F. B. Rosevear and R. H. Ferguson[4] have studied the different phases of sodium palmitate

Table 1

Name	Sodium laurate (C_{12})	Sodium myristate (C_{14})	Sodium palmitate (C_{16})	Sodium stearate (C_{18})
Subwaxy	100° C.	107° C.	117° C.	117° C.
Waxy	141	141	135	132
Superwaxy	182	176	172	167
Subneat	220	217	208	198
Neat	255	245	253	257
Isotropic melt	336	310	295	288

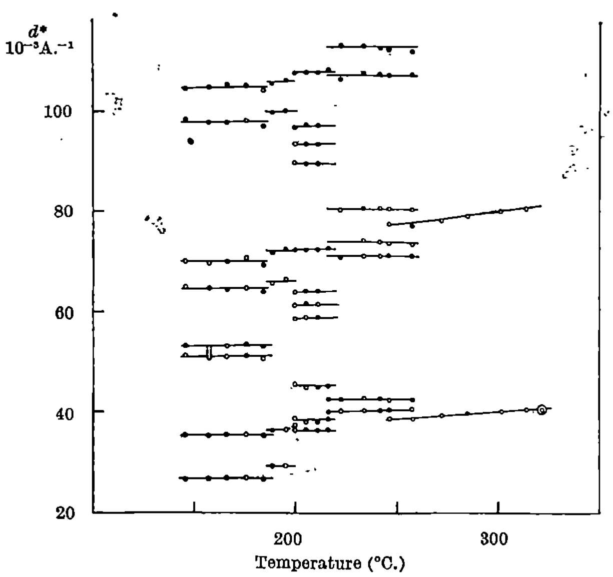

Fig. 1. Reciprocal spacings as a function of temperature for sodium laurate

by X-ray diffraction techniques. They recognized two main regions in the X-ray diagrams: the central part (0·01 A.$^{-1}$ $< s <$ 0·10 A.$^{-1}$; where $s = 2\sin\theta/\lambda$), where they observed several sharp lines, and a region in which s is of the order of 0·25 A.$^{-1}$, where they found one or two diffuse bands. They considered the position and the profile of the bands as evidence that the soap molecules are packed in a hexagonal array and rotate freely around their axes. These authors did not try to determine the crystal lattices responsible for the sharp lines.

An infra-red absorption study[6] has shown that in all the high-temperature phases, from the subwaxy to the isotropic melt, the paraffin chains are disordered and that their configuration is similar to that of a paraffin liquid.

The purpose of our investigation was to determine the liquid-crystalline structure of the different phases of sodium laurate, myristate, palmitate and stearate, by the interpretation of the sharp lines occurring in the central region of the X-ray diagrams.

We have used a Guinier-type focusing camera, which was evacuated and provided with a bent quartz monochromator. The samples were held in an electric furnace and the temperature was maintained with an accuracy of 0·5 deg. C. The soaps were produced by neutralizing alcoholic solutions of the fatty acids (supplied by the Eastman Kodak Co.). Water and alcohol were eliminated by heating the sample for 1–2 hr. *in vacuo* at 120° C. in the cell in which it was enclosed for the X-ray investigations. These precautions for avoiding water and alcohol seem to be sufficient, since X-ray diagrams show no appreciable dependence upon moisture.

We have taken at least one hundred X-ray diagrams of each soap in the temperature-range 100–350° C. In the central part of the diagrams we have observed a large number of sharp diffraction lines (sometimes more than twenty). These sharp lines form a typical pattern for every phase; the transition temperatures are in good agreement with those previously determined (see Table 1). We have plotted in Fig. 1 some of the experimental results for sodium laurate.

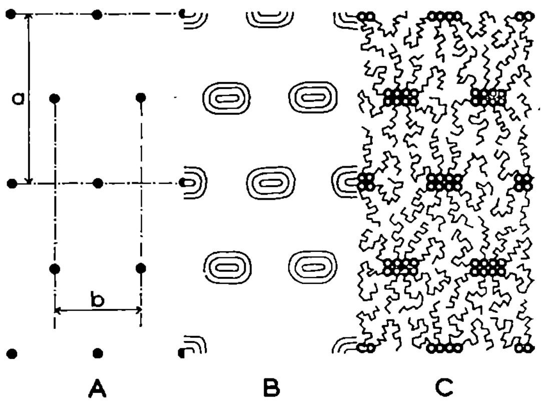

Fig. 2. (*A*) Two-dimensional centred rectangular lattice. (*B*) Electron-density projection along [001]. Contours are at equal arbitrary intervals, with the zero contour omitted. (*C*) Schematic structure of the rectangular phases

At s of the order of 0·2–0·3 A.$^{-1}$, the diagrams show the diffuse bands described by Ferguson and co-workers[4]; but we have observed that at low temperatures (more particularly in the subwaxy and the waxy phases) the bands have a fine structure, which is the more detailed the lower the temperature.

Since the experimental results are essentially the same for the four soaps investigated, we propose to describe separately the structure of every phase.

Subwaxy, waxy, superwaxy, subneat. The observed spacings are consistent with a two-dimensional centred rectangular lattice (space group $c2mm$; ref. 5) (see Fig. 2*A*). By way of example, we compare in Table 2 the observed spacings (sodium laurate at 166° C.) and the calculated spacings for a rectangular cell with sides a = 75·2 A., b = 30·9 A.

Table 2

Indices $hk0$		200	110	310	400	020	220	130	330
s (in 10^{-3} A.$^{-1}$)	exp.	26·2	35·2	51·0	53·1	64·3	70·0	97·7	105·2
	calc.	26·6	35·0	51·4	53·2	64·7	69·9	97·9	105·0

The structure (see Fig. 2 *C*) consists of a set of parallel ribbons, indefinite in length, packed in the rectangular array. The polar groups of the molecules fit into the ribbons. The paraffin chains, in a liquid-like state,

Subneat	two-dimensional rectangular	234° C.	a = 49·8 A. b = 27·0 A.	233° C.	a = 53·8 A. b = 29·1 A.	236° C.	a = 56·2 A. b = 30·6 A.	238° C.	a = 62·4 A. b = 34·4 A.
Neat	lamellar	290° C.	d = 25·3 A.	271° C.	d = 27·5 A.	278° C.	d = 29·1 A.	285° C.	d = 80·6 A.

fill up the rest of the cell. The intensities of the lines are in good agreement with this model; this is confirmed by the electron-density distribution calculated with the observed amplitudes and the signs corresponding to the model (Fig. 2 *B*).

The dimensions of the unit cell depend on the soap and on the phase; they are given in Table 3. For every soap, the higher the temperature the more symmetrical (closer to a hexagonal cell) is the shape of the unit cell.

Neat. In this phase the X-ray diagrams contain three or four lines giving Bragg spacings in the ratio 1 : 1/2 : 1/3 : 1/4, characteristic of a lamellar structure (one-dimensional lattice). The structure of the neat phase is sketched in Fig. 3 *B*.

The neat is the only phase in which the spacings are strongly dependent on temperature. The coefficient of linear thermal expansion is negative and its value approximately -5×10^{-4}/deg. C. (note that, at room temperature, the thermal expansion coefficient of the large parameter of crystalline soap is $+5 \times 10^{-5}$/deg. C.). We have observed the same thermal effect in the liquid-crystalline structures of soap–water systems[7] and we have interpreted it to mean that hydrocarbon chains are liquid-like in character.

Isotropic melt. X-ray photographs taken at a temperature a few degrees above the melting-point contain two or three fairly sharp bands corresponding to the Bragg spacings of neat soap. This observation suggests that the structure of the melt is quite similar to that of the neat phase.

A new phase. In sodium laurate, we have observed a new phase occurring between the superwaxy and subneat phases. This new phase does not seem to have been noticed by previous workers.

The lattice is three-dimensional body-centred orthorhombic, space group *Immm* (see Fig. 3 *A*); the dimensions are: $a = 55·5$ A., $b = 28·3$ A., $c = 32·7$ A. The spacings and intensities of the diffraction lines are in good agreement with a model in which the polar groups of the soap molecules pack into slightly asymmetrical disks, which pile up in the crystal, and the paraffin chains fill up the rest of the cell. This phase is not found in the other soaps.

GENETIC CONTROL OF HUMAN HAPTOGLOBIN SYNTHESIS

By DR. A. C. ALLISON

National Institute for Medical Research, London, N.W.7

THE haptoglobins, a group of serum proteins that combine with hæmoglobin, were first studied by Jayle and his colleagues in Paris[1]. They showed that the complex of hæmoglobin and haptoglobin has peroxidative activity, and that this reaction can be used to assay haptoglobin in serum. Connell and Smithies[2] have developed a sensitive technique for analysing this peroxidase activity, using hydrogen peroxide as the oxidizing substrate and guaiacol as hydrogen donor.

The observations of the French workers suggested that at least two haptoglobin types exist. One (type II) was purified by fractional precipitation of the urine of a nephrotic child and shown[3] to be a glycoprotein of molecular weight about 85,000. The other haptoglobin (type I), purified from human serum, was reported[4] to have a similar composition and a molecular weight of about 160,000. It was concluded that type I might be a dimer of type II.

With the introduction of the starch gel technique of zone electrophoresis, Smithies[5] recognized three types of human sera, which were later[6] termed types 1–1, 2–1 and 2–2. It became clear that the proteins differing in the several serum types were haptoglobins[6], Jayle's type II haptoglobin corresponding to Smithies's 1–1, and Jayle's type I to Smithies's 2–2, respectively[7].

Smithies and Walker[6] offered a simple hypothesis for the inheritance of the haptoglobin types. They suggested that a single pair of allelic genes, Hp^1 and Hp^2, segregate in human populations, the three genotypes Hp^1/Hp^1, Hp^2/Hp^1 and Hp^2/Hp^2 corresponding to the phenotypes 1–1, 2–1 and 2–2, respectively. Other family studies[8] have confirmed that this is the usual mode of inheritance of haptoglobins. However, atypical segregation has been observed[9] and modified phenotypes reported[2,10]. Moreover, in some populations relatively high fre-

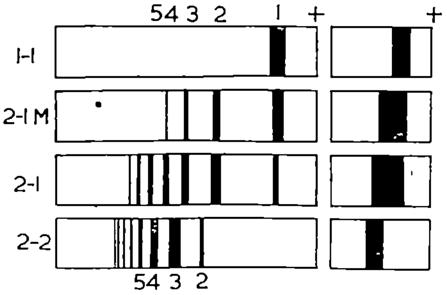

Fig. 1. Relative mobilities of haptoglobins and their complexes with hæmoglobin from the several phenotypes at *p*H 8·4, left, in starch gels, right, in starch blocks. The numbers show the supposed degree of polymerization of components and + marks the anodal side

quencies of individuals without demonstrable haptoglobins have been found[10,11]. These variations will be discussed below.

Bearn and Franklin[12] have recently studied haptoglobins and their complexes in the ultracentrifuge. In sera of type 1–1, haptoglobin was reported to have a sedimentation coefficient of 3–4 *S.*, increasing to 6 *S.* on addition of hæmoglobin, in agreement with the observations of Guinand *et al.*[3]. In the other serum types, haptoglobins and their complexes with hæmoglobin showed several peaks in the ultracentrifuge, most of those from type 2–2 sera having higher sedimentation coefficients than those from type 2–1 sera. In view of this complexity, and the numerous haptoglobin components demonstrated by starch gel electrophoresis of 2–1 and 2–2 sera[2,9,13], it was concluded that the genetical control of haptoglobin synthesis is "probably exceedingly complex". Moreover, since one of the components in the ultracentrifuge was present only in 2–1 sera, Bearn and Franklin suggested that the haptoglobin genes might interact in the heterozygote to produce a hybrid product like those described in doves[14] and rabbit[15] and human[16] blood groups.

This system is of unusual interest, then, in relation to the genetic control of protein synthesis, for not only does the heterozygous individual produce proteins different from those in either homozygous type, but also in two of the types the haptoglobins consist of several fractions. No other genetic system is known in which a single locus controls the specificity of more than one protein[17]. It therefore seems worth while to present a hypothesis for the genetic control of haptoglobin formation which brings this group of proteins into line with others and appears to provide an adequate explanation for all the findings so far reported.

The differences between haptoglobins in the three types will first be briefly recapitulated (Fig. 1). In type 1–1 sera only a single haptoglobin is present, having a relatively high mobility on filter paper and starch block electrophoresis and also in starch gels at *p*H 8·4–8·6[2,5,12,13]. Ultracentrifugal studies show only a single component of relatively low molecular weight[3,12]. Type 2–2 haptoglobins appear as a single component when submitted to electrophoresis on filter paper and in starch blocks, having a lower anodal mobility than type 1–1 haptoglobin. However, when 2–2 haptoglobins are submitted to electrophoresis in starch gels, numerous components, becoming fainter towards the origin, are resolved. Since these components do not differ in charge (as shown by the uniform mobility on filter paper and in starch gels), it is a reasonable inference that they differ in size, which is known to affect mobility in starch gels[18]. This inference is strengthened by their heterogeneity in the ultracentrifuge. Indeed, if the frictional coefficients of 1·4–1·6 calculated for purified haptoglobins[3,4] are taken together with sedimentation coefficients of 2–1 and 2–2 haptoglobins extrapolated to zero protein concentration[12], it seems likely that a polymer series is present. The lowest (4 *S.*) component, present only in 1–1 and 2–1 sera, would represent a monomer (molecular weight about 80,000), the second (6–7 *S.*) a dimer (molecular weight about 160,000), the third a trimer, and so forth, dimers and higher orders being present only in 2–1 and 2–2 sera. In 2–1 sera one haptoglobin component is identical in mobility in starch gel electrophoresis with the haptoglobin of type 1–1. Other haptoglobin bands consistently show a higher electrophoretic mobility in starch gels than the haptoglobins in type 2–2 sera. In modified type 2–1 sera (2–1 *M*), the first component is greater and the second component is smaller than usual, and very little of the other components is present; this type is especially common in Africans[10].

An attempt will now be made to provide an explanation for these seemingly confusing observations. It is suggested that recently synthesized haptoglobin molecules (of molecular weight about 80,000) have complementary combining sites (1 and 2) through which aggregation can take place under favourable conditions. The protein product of the Hp^1 gene is Hp1, which has only a single combining site (Fig. 2). Since the complementary combining site is lacking, only monomers are present in Hp^1/Hp^1 homozygotes. The product of the Hp^2 gene, which can be termed Hp2, has both complementary combining sites 1 and 2, and also a lower negative charge at *p*H 8·4 than Hp1. Hence in Hp^2/Hp^2 homozygotes the haptoglobin molecules can combine with one another, so that polymers are formed. It would appear that a small proportion of dimers, a high proportion of trimers and progressively lower proportions of tetramers and higher polymers result. The different polymers are separated by starch gel electrophoresis, so that numerous bands are seen, becoming progressively fainter towards the origin.

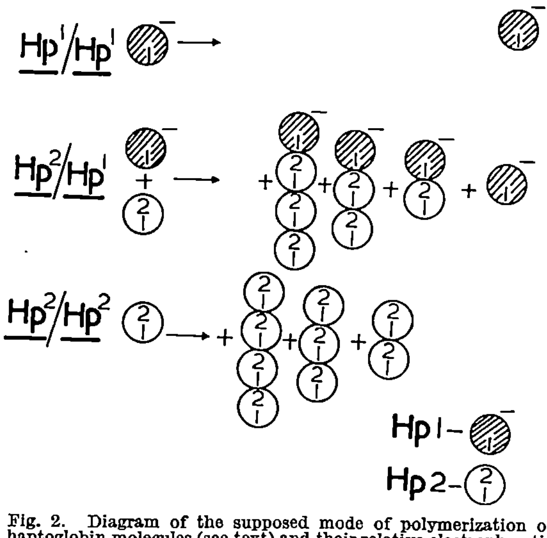

Fig. 2. Diagram of the supposed mode of polymerization of haptoglobin molecules (see text) and their relative electrophoretic mobilities in starch gels. Only the first three polymers are shown. Origin to the left and anode to the right. For convenience the polymers are shown as linear; in practice they are more likely to be globular

In heterozygotes, Hp1 and Hp2 molecules are formed side by side (like A and S hæmoglobins in sickle-cell heterozygotes). These form mixed polymers, each containing only one Hp1 molecule, which has a single combining site. The commonest polymer is the dimer, with progressively fewer trimers, tetramers and higher orders. Since Hp1 has a greater negative charge than Hp2 at pH 8·4, the mixed Hp1, Hp2 polymers would have a higher electrophoretic mobility than the polymers Hp2, Hp2 on both starch block and starch gel electrophoresis. However, in the absence of masking of charged groups, all Hp1, Hp2 polymers would have the same charge and therefore a similar electrophoretic mobility in starch blocks or on filter paper; and the same would be true of Hp2, Hp2 polymers. Nevertheless, if approximately equal proportions of Hp1 and Hp2 are formed in heterozygotes, all the Hp2 but only a fraction of Hp1 molecules will polymerize; hence the residual Hp1 molecules will form a component identical with Hp1 in Hp^1/Hp^1 homozygotes.

The genetic variant 2–1 M is readily explained by supposing that a higher proportion of Hp1 than usual is synthesized. There will therefore be more residual Hp1 monomer and less Hp1, Hp2 dimer than in type 2–1, with only very small proportions of higher polymers.

The genetic control of haptoglobin synthesis is analogous in some respects to that of the human hæmoglobin types. Hæmoglobins S and C differ from normal adult hæmoglobin (A) in charge: this appears to be due to the substitution of a valine or lysine residue for glutamic acid, respectively, in each half-molecule[19]. Although the differences between them are so small, S is the only hæmoglobin which polymerizes in the absence of oxygen into highly asymmetrical units, this process being responsible for sickling and birefringence of erythrocytes in susceptible subjects[20]. Moreover, hæmoglobin S can form mixed polymers with hæmoglobins C or A [20], in somewhat the same way that it is suggested that Hp2 molecules can form mixed polymers with Hp1. Here the analogy ends, for hæmoglobin polymers seem to be due to the formation of secondary intermolecular bonds which are easily disrupted, for example, by oxygen or urea[20]. The starch gel electrophoretic patterns of haptoglobins, on the other hand, suggest that the polymerization is relatively stable, being unaffected by the presence of 8 M urea and relatively wide changes of pH (1·7 to 9·0)[2,13]. Moreover, when the protein in one band is eluted from starch gels and again submitted to starch gel electrophoresis, it runs as a single component with its original mobility[2,13]. These results exclude metastable polymerization[21] and suggest that the haptoglobin polymers may be held together by primary bonds. The nature of the bonding is at present under investigation. If it proves possible to break down Hp2 polymers, the resulting monomers should, when mixed with Hp1 molecules in various proportions, yield 2–1 and 2–1 M patterns, thereby providing experimental confirmation of the hypothesis here advanced. It may also explain two further problems: why polymerization is limited in Hp^2/Hp^2 subjects, so that low-order rather than higher-order polymers occur, and why Hp1 does not interact (at any rate, rapidly) with Hp2, Hp2 polymers when they are mixed[12,13].

The other genetical problem posed by the haptoglobins is the presence in several populations of persons without demonstrable haptoglobins, to which attention was directed by Allison *et al.*[11]. A number of sera have now been re-tested by the sensitive peroxidase technique of Connell and Smithies[2]. Only two British sera out of a total of 632 examined over a period of four years have failed to show haptoglobins by electrophoretic or peroxidative analysis. On the other hand, no haptoglobins could be demonstrated by the peroxidase reaction in 14 out of 20 sera from West Africans previously thought to be ahaptoglobinæmic.

The question then arises whether lack of haptoglobins in these subjects could be secondary to hæmolytic anæmia or liver disease[22,23]. This seems unlikely. The British subjects without haptoglobins on repeated tests were apparently healthy adults, with normal blood counts; and similar observations on British subjects have been presented by Harris *et al.*[8]. The Africans studied were also apparently healthy adults, who should have had considerable resistance to malaria. Ahaptoglobinæmia in Africans was not correlated with the presence of abnormal hæmoglobins S or C, which in the heterozygous condition are not associated with low haptoglobin levels, although absence of haptoglobins has been reported in patients homozygous for abnormal hæmoglobin genes[22]. Furthermore, the recent demonstration by Giblett[10] that some American Negroes lack haptoglobins rules out the possibility that ahaptoglobinæmia is always secondary to malaria, malnutrition, liver disease or other factors in the African environment.

It seems likely, then, that a small proportion of Caucasians and a higher proportion of Africans congenitally lack haptoglobins. In some cases, at least, this does not seem to be due to homozygosity for a third, 'silent' allele at the Hp locus. Mothers of ahaptoglobinæmic subjects who have been of phenotype 2–1 could not have been carriers of the silent alleles[8,9,13], on the hypothesis here advanced or any other plausible hypothesis. The most likely genetic explanation for ahaptoglobinæmia seems to be homozygosity for a recessive suppressor gene at another locus[8,9,22], but further family studies would be desirable.

Calculation of Erosion in Space from the Cosmic-Ray Exposure Ages of Meteorites

VERY little is known about erosion in space—the action of dust, gas, ions and electrons in wearing away material from exposed surfaces in interplanetary space. A cosmic-ray exposure age is obtained from the measurement of one radioactive and one stable spallation isotope produced in a meteorite by cosmic rays. A new interpretation of this age indicates that it sets an upper limit to the erosion-rate of a meteorite in space. The more obvious interpretations in terms of meteoritic break-up and planetary perturbational effects may remain valid.

The cosmic-ray exposure age is determined from the spallation isotope content of a meteorite, with the assumption that the spallation-rate does not vary with time. If erosion occurs in space, however, the spallation-rate in the distant past would have been smaller than in recent times because of the greater amount of shielding material. Hence, due to erosion in space, the measured cosmic-ray exposure age is less than the interval since the meteorite was exposed to cosmic rays. Consequently, the cosmic-ray exposure age gives an upper limit to the rate of erosion in space.

We shall base our discussion on the argon exposure age[1] of the Sikhote–Alin meteorite. The value of 5×10^8 years was obtained[1] from the number of argon-38 atoms (stable isotope) and the decay-rate of argon-39, a radioactive isotope with a half-life of 260 yr. The tritium (helium-3) ages of two iron[2] and one stone[3] meteorite have also been measured; however, the argon exposure age is subject to fewer uncertainties than the tritium (helium-3) age.

We shall assume that the rate of production of argon-38 near the centre of a large iron sphere of radius R obeys the attenuation rule:

$$\mathrm{d}^{38}\mathrm{A}/\mathrm{d}t = C \exp(-R/72) \text{ for } R \geqslant 100 \text{ cm.}$$

where C is a constant determined by the spallation properties of the iron nucleus and the cosmic ray flux.

The Sikhote–Alin meteorite was quite large: the argon-39 radioactivity in the measured sample was about one-ninth the activity expected in a small unshielded body. If the rate of erosion in space is designated by E and if r is the radius of the meteorite just before it struck the atmosphere, then the rate of production of argon-38 at t years ago was $C \exp\{-(r + Et)/72\}$. The present rate of production is $C \exp(-r/72)$. The measured cosmic-ray exposure age, 5×10^8 yr., is given by the expression $\int_0^T (\mathrm{d}^{38}\mathrm{A}/\mathrm{d}t)\mathrm{d}t/C \exp(-r/72)$, where T is the time that the meteorite existed as a body exposed to cosmic rays. If the attenuation rule is substituted into this expression, then the following relation is obtained:

$$5 \times 10^8 \text{ years} = (1 - \exp(-Et/72)/(E/72)$$

where E is the rate of erosion.

Since the time T is greater than the measured exposure age, 5×10^8 years, the upper limit to the rate of erosion E is $1{\cdot}5 \times 10^{-7}$ cm./yr. for an iron meteorite. This rate is somewhat smaller than an estimate made by one of us (F. L. W.)[4].

Observations of the Lithium Lines in the Twilight Airglow in the Northern Hemisphere

THE recently published discovery of the lithium resonance line in the twilight airglow by Delannoy and Weill[1] and further observations of the emission by Gadsden and Salmon[2] have led to a discussion as to the origin of the lithium atoms in the upper atmosphere. Barbier, Delannoy and Weill[3] have considered the possibility of marine and meteoric origins for the lithium and have favoured the latter hypothesis because the derived abundance ratio lithium/sodium agreed better with the ratio for the meteoric material. Donahue[4] has suggested that the lack of linearity in the relation between sodium brightness and abundance could make ambiguous any conclusions based on the lithium/sodium brightness ratio alone. A third possibility suggested by the U.S.A. International Geophysical Year Committee[5], and supported further by Barber[6], is that the lithium originates from 'hydrogen' bomb tests at high altitude; it is suggested, in particular, that the high-altitude Johnston Island test of August 1, 1958, was responsible for the lithium emissions reported by Gadsden and Salmon from Antarctica and New Zealand. In view of the uncertainty of present knowledge of the behaviour of the lithium emission, an observation from a station in the northern hemisphere should be of interest.

Twilight spectra covering the region 6000–7000 A. have been obtained at Saskatoon regularly since January 1959. An $f/0{\cdot}8$ auroral grating spectrograph[7] was used to photograph the spectrum on Kodak 103 *a–F* plates. During the exposures the spectrograph was guided according to an exposure programme which kept it pointing at the point in the Sun–zenith plane where the geometrical shadow height was 80 km. Following such a programme, a 30-min. exposure may be obtained during a single twilight with a zenith angle range of 0–83°.

A very weak lithium line was obtained in this way on a plate exposed on four occasions during clear twilight during the period January 10–21, 1959. The total exposure time was 115 min. Comparison of this spectrum with the spectrum of a calibrated source of low brightness led to a value of 30 rayleighs for the zenith brightness of the lithium emission for a height of 80 km. of the geometrical shadow.

An estimate of the abundance of lithium in the upper atmosphere can be made from the observed brightness. First the brightness when the lithium layer is fully illuminated must be estimated. The correction factor required depends on the distribution of the lithium with height. A value of about 5 for this correction factor was obtained by assuming the lithium distribution to be the same as that for sodium and then applying the theory developed by Hunten[8] to calculate a theoretical relation between brightness and geometrical height of shadow. A value of 150 rayleighs is thus estimated for the maximum zenith brightness when the lithium layer is fully illuminated by the Sun. The rate coefficient for the resonance fluorescence process for lithium obtained from the standard equation[9] is 17 photons/sec. per illuminated atom. This leads to the conclusion that the lithium abundance over Saskatoon in January was about 9×10^6 atoms/cm.^{2}. The sodium abundances estimated for the same period of observation from data kindly provided by Dr. D. M. Hunten may have been as high as 20×10^9 atoms/cm.^{2}. Consequently, the lithium – sodium abundance ratio was about 45×10^{-5} compared with 200×10^{-5} for meteors and $2 \cdot 3 \times 10^{-5}$ for sea water. If ionization is taken into account[3], it is possible that the abundance ratio derived from our measurements should be somewhat higher.

This result for the lithium – sodium abundance ratio, neglecting ionization, falls between the values for sea water and meteors, and cannot be considered as decisive evidence against either hypothesis in view of the uncertainties of the measurement. Moreover, since the chemical and physical properties of lithium and sodium (and their compounds) are considerably different, it is by no means certain that the abundance ratio in the upper atmosphere should be close to that of the source. As to the possibility of the lithium arising from bomb tests, it is possible that the lithium detected above Saskatoon in January is a remnant of that introduced into the atmosphere last August. However, it is also possible that the brightness of the emission in the southern hemisphere in August and September is associated with a seasonal variation of the lithium abundance; this abundance might well show a maximum about 2½–3 months after midwinter, as is the case for sodium in the northern hemisphere[10]. This question can be determined only by further systematic measurements.

Sub-surface Temperatures on the Moon

RECENTLY, Fremlin[1] has suggested that craters on the Moon may be filled with dust to considerable depths and that extremely high temperatures may be attained in them. While the effects described by him must exist, it should be pointed out that the extreme values he predicts are obtained by using a value for the thermal conductivity of the dust which is probably much too low and combining with this a value of the heat flux which is probably much too high. These points will be discussed in order.

Information about the thermal conductivity near the surface is obtained from optical and radio micro-wave observations of the variation of the surface temperature during an eclipse or throughout a lunation. These yield a value of $(K\rho c)^{-1/2}$, where K, ρ and c are the thermal conductivity, density and specific heat of the material near the surface (assumed to be independent both of temperature and depth). The optical eclipse observations of Pettit and Nicholson[2] were first reduced by Epstein[3], who deduced a value of 120 for $(K\rho c)^{-1/2}$, the units being C.G.S., calorie and degrees centigrade; since this is much higher than that for solid rock (about 20) he attributed it to a covering of 'pumice' or volcanic ash. Later, using more refined analysis and discussing both the variation of surface temperature during an eclipse and throughout a lunation, Wesselink[4], Jaeger and Harper[5], Lettau[6] and Jaeger[7] showed that Epstein's value was too low and independently obtained values of $(K\rho c)^{-1/2}$ of the order of 1,000. Similar values were obtained by Piddington and Minnett[8] and Jaeger[9] from the radio micro-wave observations. Taking $\rho = 2$, $c = 0 \cdot 2$, this corresponds to $K = 2 \cdot 5 \times 10^{-6}$: this low value was attributed to dust from meteoritic or other sources.

The agreement with experiment of calculations based on the above assumptions is good but by no means perfect, and all writers have recognized that it could be improved if the conductivity increased with either depth or temperature. In the absence of knowledge of a likely law of the variation of conductivity with temperature, discussion has been concentrated on the variation with depth, and it has been shown[5,8,9] that a rather better fit is obtained with a model consisting of a few millimetres of dust with $(K\rho c)^{-1/2} = 1{,}000$ resting on a substratum with $(K\rho c)^{-1/2} = 120$. This substratum might be composed either of tuffaceous material of volcanic origin or of material composed of rock fragments of all sizes produced by erosion due to thermal stresses. Recently, Muncey[10] has obtained a better fit with the radio micro-wave observations with a model in which both K and c are proportional to the absolute temperature with a value of $(K\rho c)^{-1/2}$ of 200–300 at 300° K. This low value, however, is inconsistent with with the optical eclipse observations, since it gives temperatures in the umbral phase which are about 60 deg. too high.

Taking $\rho = 2$, $c = 0 \cdot 2$, the discussion above leads to a conductivity of the order of $2 \cdot 5 \times 10^{-6}$ at the surface, increasing in a few millimetres to 2×10^{-4}. These figures may be compared with the value of $7 \times 10^{-7} h^{1/2}$, where h is the depth below the surface, used by Fremlin. If this value 7×10^{-7} at a depth of 1 cm. were used for the surface conductivity, it would give calculated values of temperatures in the umbral phase of a lunar eclipse which are 25 deg. K. too low.

Turning to the values for the lunar heat flux used by Fremlin, he assumes that the average rate of heat production over the volume of the Moon due to radioactivity is that of 2 p.p.m. of uranium, corresponding to a total heat production of about 10^{20} cal./year. If the whole of this heat is lost by radiation from the surface, the surface heat flux would be $8 \cdot 4 \times 10^{-6}$ cal./cm.^{2} sec., which is seven times the terrestrial value. There is good evidence (Birch[11]) that the average rate of production of heat in the Earth is nearly the same as that of the chondritic meteorites, the total rate of production of heat in the Earth being of the order of $2 \cdot 3 \times 10^{20}$ cal./year, or not much more than twice that assumed by Fremlin for the Moon ; if the whole of this heat were radiated from the surface, the surface heat flux would be $1 \cdot 4 \times 10^{-6}$ cal./cm.^{2} sec., which is in good agreement with the observed value of $1 \cdot 2 \times 10^{-6}$. An average heat production in the Moon at the chondritic rate would give a lunar surface heat flux of the order of $2 \cdot 3 \times 10^{-7}$ cal./cm.^{2} sec., and this is the value which probably should be assumed in the absence of evidence to the contrary. If the production of heat at the rate assumed by Fremlin were distributed over the volume of the Moon, melting would occur in a relatively short time : if, by a process of differentiation, it were concentrated into a crustal layer, not only would the concentration of radioactive elements near the surface be higher than in any terrestrial rocks, but, again, melting temperatures would be reached at shallow depths even in the absence of any blanketing dust. The triaxial figure of the Moon requires that there should have been substantial strength in the interior for a considerable time in the past.

Whether the blanketing effect described by Fremlin, which undoubtedly must exist, is of importance or not depends entirely on the values assumed for the conductivity and the lunar surface heat flux. Neglecting time effects in blanketing, lateral flow to better conducting regions, and the fact that the Moon is not in thermal equilibrium, all of which tend to reduce the magnitude of the effect, Fremlin deduces an excess temperature of 1,200° C. at a depth of 25 m. ; with the same high heat flux and the conductivity of 2×10^{-4} deduced for the substratum from the eclipse observations, this figure would be reduced to 105° C. For a heat flux of the terrestrial value, $1 \cdot 2 \times 10^{-6}$ cal./cm.^{2} sec., the corresponding results would be 170° C. and 15° C. ; while with the flux of $2 \cdot 3 \times 10^{-7}$ cal./cm.^{2} sec. corresponding to the chondrite model they would be 33° C. and 3° C., respectively.

Finally, it should be said that this matter is just within the range of experiment. Since the optical effects arise from a thin layer near the surface while the radio waves originate from a region some metres in thickness, the mean temperature as shown by micro-waves should be greater than that derived from optical observations if there is any general increase of temperature with depth due to the lunar heat flux. Using Fremlin's value $24\sqrt{h}$ for the temperature at depth h and a value $\alpha = 0 \cdot 025$ given by Piddington and Minnett[8] for the micro-wave attenuation coefficient α, the difference between the mean temperatures deduced from micro-wave and optical observations should be 135 deg. C. This figure is probably far too low, since the value of α used is of the order of that for dry soil and the attenuation for lunar surface material should be much lower. This calculation provides an independent indication that the temperatures deduced by Fremlin are much too high. But there is some evidence that the mean micro-wave temperature is a few degrees higher than the mean optical temperatures and a careful analysis might lead to information about the lunar heat flux.

Prof. Jaeger is quite right in pointing out that I have used a high figure for the radioactivity of the Moon, and also that my value for conductivity near the surface is lower than the mean value calculated from observations. This does not necessarily prove that my values are wrong. I assume Kozyrev's observations of hot gases to be reliable. They would not have been expected on the basis of conventional views of lunar characteristics and presumably, therefore, conventional views must be modified. I have suggested some modifications, which may easily be wrong. The more conservative of Prof. Jaeger's figures, however, must almost necessarily be wrong. They show that phenomena observed by Kozyrev could not have occurred.

I do not think that there is a contradiction between my figures for conductivity and experiments done so far. My whole argument is based on the idea of large thicknesses of dust in specific limited areas. Measured radiation from the lunar surface has been averaged from considerable areas (in the micro-wave work, nearly the whole of the Moon's disk) within which any bare rock would be expected to have a thermal conductivity very much higher than the mean value observed. Small areas of high conductivity could have a large effect on the calculated average temperatures on the dark side of the Moon. Their increasing share of the total radiation at the lower average temperatures might quite possibly explain the small divergence shown between Pettit's infra-red observations during a lunar eclipse and Prof. Jaeger's calculations (his reference 9, Fig. 1). These calculations show the apparent variations of temperature with time to be expected for a uniform lunar surface with values of $(K\rho c)^{-1/2}$ from 20 (bare rock) to 1,370. The calculated temperatures fall too fast in the umbral phase. Instead of assuming inhomogeneity with depth, let us assume the existence of two types of surface, one bare rock ($K\rho c^{-1/2} = 20$) and one a dust ($K\rho c^{-1/2} = 2,700$) of about five times lower conductivity than the mean value giving best agreement. Then we can get an almost exact fit with Pettit's observations if the bare rock covers 4·8 per cent of the total area—a not unreasonable result. (The two volumes of conductivity are quite arbitrary, having been chosen simply to make computation from Prof. Jaeger's calculations as easy as possible.) If we do not limit ourselves to two kinds of surface only, or if we allow for a difference of albedo, there would be no difficulty in accommodating adequate areas of conductivity well below even those assumed in my original communication.

It is in any event difficult to believe that the alternative picture suggested by Piddington and Minnett, of a uniform 1-mm. layer of dust, over mountain-side and plain alike, can be more than a convenient analytical model.

With regard to the supposed radioactivity, I am on weaker ground. I had failed to consider the need for high mechanical strength to maintain the observed shape of the Moon, and I am grateful to Prof. Jaeger for pointing this out. It is clear that the average lunar radioactivity must be well below that given for the Earth's crust, unless the thermal conductivity of the solid lunar rock is a good deal higher than hitherto supposed. The obvious way out is to suggest a non-uniform distribution of radioactive material. The likelihood of this depends on what we assume about lunar history, which seems too large a subject to discuss here.

My main contention remains: that I am willing to feel doubt about any of my assumptions, but am unwilling to give up the entire picture until an alternative explanation of Kozyrev's observation is given.

Magnetostriction and Palæomagnetism of Igneous Rocks

In a recent communication, Stott and Stacey[1] report on a "crucial experiment" from which they conclude: "This excellent agreement between the dip and the directions of artificial thermoremanent magnetization of the stressed and unstressed rocks indicates that large systematic errors due to magnetostriction are most improbable in igneous rocks of types normally used for palæomagnetic work". This experiment was intended to test the proposals[2] and measurements[3] bearing on the role of magnetostriction in rock magnetism. We present here our reasons for believing that the experiment was not crucial and that the conclusion is not justified.

The magnetic fraction of natural igneous rocks almost without exception consists of mixtures of two or more crystalline phases. These phases may be distinguished magnetically by a number of parameters which are dependent on structure, composition and particle-size. Commonly these segregated phases are intimately intermingled, for they developed from pre-existing simpler phases which were stable only at a higher temperature. As a result, there may be strong interaction of the magnetic fields of the different phases on one another. The magnetic properties of the bulk samples are thus determined both by the properties of the individual phases and by the nature of the magnetic interactions among them. The degree to which the phases have become segregated and the size scale on which the intergrowth textures have developed depend, among other things, on composition and thermal history. Kawai *et al.*[4] have demonstrated that in Japanese effusive rocks, unmixing at low temperatures is a process requiring tens of millions of years, whereas, in contrast, low-temperature unmixing can be detected in as little as three days in a particular sample which was first held at 750° C. for three days and was then quenched to room temperature. As a result of unmixing, the magnetic properties of rocks change conspicuously. At elevated temperatures, the rate of homogenization of unmixed phases varies greatly among different samples; heat treatment at 650° C. for 15 min. is sufficient to cause gross changes in the phase structure and composition of the magnetic fraction of numerous rocks. This fact has been observed repeatedly in many laboratories and is abundantly documented, especially in the Japanese works.

Stott and Stacey ignore these facts, assuming that their experiments on natural samples which have been heat-treated 15 min. at 650° C. and then cooled over a period of several hours while under axial stress give realistic replicas of typical conditions in Nature. Clearly, this assumption is not safe, except possibly for the case of some young rocks which were cooled quickly; it does not permit generalizations, for example, about the possible role of magnetostriction in influencing the directions of residual magnetization of samples of a dolorite sill which cooled over a period of hundreds of years while under load, remained under a load that decreased over millions of years while magnetic phases were segregating from original simpler phases, and finally were brought to the laboratory for measurement.

We feel that this oversight by Stott and Stacey should be pointed out for, in our opinion, there are already too many instances where conclusions founded improperly have given the subject of palæomagnetism a questionable status.

Borides and Silicides of the Platinum Metals

A great number of intermediate phases exist in the systems of boron with platinum metals[1] but very little information about these phases is available. X-ray crystallographic studies of platinum metal borides have been initiated at this Institute, and we have determined three new structure types (tentatively called Ru_7B_3, RhB and IrB_{1-2} types) which will be discussed briefly in this communication. We have found evidence that the 'Rh_2B' phase with *C*23 structure reported by Mooney and Welch[2] might really be Rh_2Si.

The alloys were prepared by melting mixtures of the elements (99·7–99·8 per cent pure) in an arc furnace. The crystal structures were determined with single-crystal methods, while the lattice parameters were obtained from powder photographs.

The Ru_7B_3 structure. This structure is hexagonal and was recently described in detail[3]. The space group is $P6_3mc$ with two formula units in the unit cell. Ru_7B_3 and Rh_7B_3 crystallize in this structure, which is especially interesting for its close similarity to the Cr_7C_3 structure[4].

The RhB structure. The most probable space group of this orthorhombic structure is *Cmcm*. The four

Table 1. CRYSTALLOGRAPHIC DATA OF SOME BORIDES AND SILICIDES OF THE PLATINUM METALS

Substance	Space group	Lattice parameters (A.)
Ru_7B_3	$P6_3mc$	$a = 7\cdot46_7$, $c = 4\cdot71_3$
Ru_7B_3	$P6_3mc$	$a = 7\cdot47_5$, $c = 4\cdot77_6$
RhB	*Cmcm*	$a = 3\cdot30_3$, $b = 5\cdot68_7$, $c = 4\cdot34_3$
PtB	*Cmcm*	$a = 3\cdot35_6$, $b = 5\cdot80_9$, $c = 4\cdot06_3$
IrB_{1-2}	$I4_1/amd$	$a = 2\cdot81$, $c = 10\cdot27$
Ru_2Si	*Pnma* (*C*23 type)	$a = 5\cdot27_9$, $b = 4\cdot00_5$, $c = 7\cdot41_8$
Rh_2Si	*Pnma* (*C*23 type)	$a = 5\cdot40_8$. $b = 3\cdot93_0$, $c = 7\cdot38_3$

rhodium atoms of the unit cell are situated in 4(*c*) with $y = 0\cdot167$. The boron atoms occupy the 4(*b*) position, which corresponds to octahedral holes in the metal skeleton. The final *R*-value of the 45 observed *0kl* reflexions was 8·9 per cent. PtB is isomorphous with RhB.

The IrB_{1-2} structure. In iridium–boron alloys around the equiatomic composition a phase with simple structure was observed. Since from structural reasons the ideal composition of this phase probably is IrB_2 it will be denoted IrB_{1-2}. The space group is $I4_1/amd$ with four iridium atoms in 4(*a*). With this arrangement of the metal atoms an *R*-value of 9 per cent was obtained for the thirty observed *h0l* reflexions with $\sin\theta/\lambda > 0\cdot8$. Eight boron atoms can be accommodated in 8(*e*) with $z \sim 0\cdot42$, but this position is probably only partly occupied. The boron atoms have the same environment as those in the AlB_2 structure.

Borides and silicides of the C23 *type.* We have found that intermediate phases of the *C*23 type exist in the Ru–Si and Rh–Si systems, but we could not confirm that 'Rh_2B' has this structure. It does not seem unlikely that the 'Rh_2B' crystals studied by Mooney and Welch[2] in reality had the composition Rh_2Si. We would like to put forward the following arguments to support this suggestion. (1) The ability of amorphous boron to reduce silica has been pointed out already by Moissan[5], and recently[6] it has been shown that nickel–boron samples easily react with silica to form Ni_6Si_2B. Thus, it is not unreasonable to assume that also rhodium–boron samples are able to react with silica to form alloys containing silicon. (2) The lattice parameters reported for Rh_2B ($a = 5\cdot42$ A., $b = 3\cdot98$ A., $c = 7\cdot44$ A.) are within experimental errors equal to (or slightly larger than) those of Rh_2Si (see Table 1). If 'Rh_2B' and Rh_2Si were isomorphous, one would expect the unit volume of the former to be smaller than that of the latter. (3) The experimental density of the 'Rh_2B' alloy of Mooney and Welch[2] was 10·5 gm./cm.^{3}, which agrees better with the calculated value for Rh_2Si (9·90 gm./cm.^{3}) than with that for 'Rh_2B' (8·96 gm./cm.^{3}). (4) The published intensity data for 'Rh_2B' are compatible with our suggestion. If the calculated *h0l* structure factors for Ru_2Si (which we have refined from single-crystal data) are compared with those observed from 'Rh_2B', an *R*-value of 0·21 is obtained, whereas the value of 0·26 was reported for 'Rh_2B'. (5) Finally, the average Rh–B distance in 'Rh_2B' is 2·50 A., which is much longer than one would expect for metal–boron contacts (in Ru_7B_3 the average *Me*–B distance is 2·16 A., in RhB 2·19 A.), whereas 2·50 A. is a very reasonable Rh–Si distance.

It is also possible that the reported Pd_3B_2 phase[1] might have been Pd_2Si (perhaps with dissolved boron), which crystallizes in the revised (hexagonal) *C*22 structure[6,7].

We wish to thank Prof. G. Hägg for his kind interest and the European Commission of Air Research and Development Command for financial support (Contract No. *AF*61(052)-40).

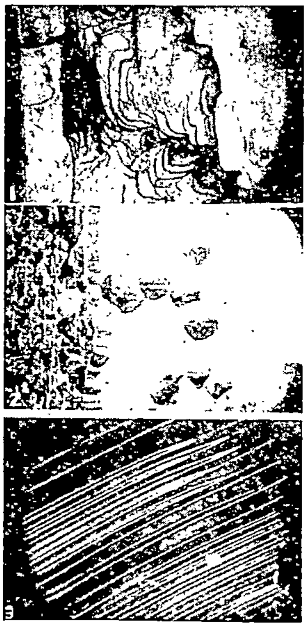
Slip Sources on Sodium Chloride Surfaces

MANY experiments have been carried out with sodium chloride crystals to investigate the Joffé effect, according to which the dissolution of surface layers by surrounding solvents results in an improvement of the plastic properties of the crystal. Hollomon and Fisher[1] suggested that this might be due to surface sources of slip which play an important part during the initiation of plastic flow.

Sodium chloride crystals were grown from a melt and their surfaces investigated with an opaque illuminator microscope. A set of small lines was observed. The crystals were then put in a not quite saturated aqueous solution of sodium chloride, which acted as an etching reagent. After a few minutes of etching the solution was made supersaturated by temperature regulation so that a slow growth started on the etched surface. A typical result is shown in Fig. 1. It is believed that the etching revealed slip sources which then became amplified by the subsequent epitaxy from the supersaturated solution. The curved lines may be parts of Frank–Read sources, which usually cover the surfaces of sodium chloride crystals grown from a melt[2]. On surfaces which do not contain slip sources the epitaxy reveals a cubic structure without curvature.



Figs. 1–3. (× 125)

Fig. 2 shows a specimen which was etched for a few minutes in 80 per cent alcohol. Etch pits became visible. On the left the surface is crowded with pits, on the right the pits are better resolved. As the pits are pointed they may be dislocations[3]. The left side seems to be the result of a crack passing slowly through the crystal. Such cracks are known to create a large number of dislocations at their edge.

If the crystals are heated to a high temperature (600° C.) and quenched, discontinuous lines become visible after etching. Fig. 3 shows a typical example on a dark field. It is suggested that the discontinuous lines consist of dislocations piled up against some obstacle.

If the surfaces are dissolved in water the number of observable slip sources is considerably reduced.

This work was carried out in the Institute for Experimental Physics of the University of Technology, Budapest. I wish to thank B. Jeszenszky for valuable discussions. A detailed paper will be published in *Acta Physica Hungarica*.

Unpleasantness of Distorted Sounds : a Criterion derived from the Distortion Spectrum

For lack of any proved method of objective assessment the degree of non-linear distortion permissible in transmission systems which handle high-quality speech and music programmes has been decided, up to the present, entirely on the basis of long experience. While collecting data to support a more factual approach to this subject the following experiments have been made.

Pulses of pure tone, rather like staccato piano notes, have been distorted in various ways and the 'unpleasantness' of the resulting sounds have been compared, and an objective criterion, C_t, computed. This shows satisfactory correlation with the unpleasantness and can be defined as follows:

$$C_t = \sum_{2}^{n} n^2 (p_n - t); \quad (p_n - t) \text{ positive}$$

where n is harmonic number, p_n is percentage amplitude of nth harmonic and t that percentage of the signal (at its crest) which is just audible.

When the level of the crest of the pulse is 70 phons, and the sounds are presented under good listening conditions (for example, ambient noise in the region of 30 phons) a value of $t = 0{\cdot}2$ gives good correlation with subjective assessment. It is suggested that $t = 0{\cdot}5$–$1{\cdot}0$ may be more appropriate so far as domestic broadcasting is concerned. Since t is that harmonic percentage which is just audible, the value of t will fall below these figures if the signal/noise ratio is increased, or rise if the ratio is reduced.

The validity of the criterion C_t has been tested by setting up pairs of distortion spectra, which differ radically both in their general character and in their band-width, and adjusting one of the spectra until the two sounds are equally unpleasant. If the signal frequency lies in the range 250–1,500 c./s., the value of the criterion C_t derived from each spectrum will then be substantially the same, provided the appropriate value of t is adopted; anomalies occur outside this frequency-range.

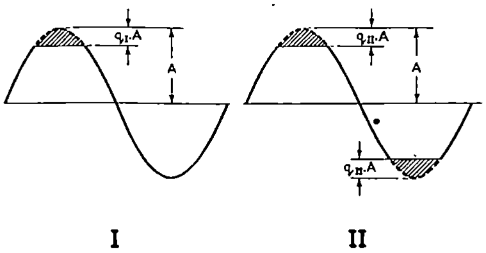

Fig. 1

A form of distortion which is easily adjusted and controlled is shown at I in Fig. 1; the proportion q_I of the amplitude, A, of the sine-wave can be varied by adjusting the steady bias applied to a diode shunting the signal path. The criterion C_t increases roughly as $\sqrt{q}$, when t is made very small or zero. Distortion of the type shown at II in Fig. 1 is often found, although in a form very considerably attenuated by negative feedback, in high-power (for example, 150 kW.) modulating-amplifiers for amplitude-modulated radio transmitters; in this case both positive- and negative-going parts of the wave are limited. The correlation between the criterion C_t and the unpleasantness of both types of distortion has been investigated, and a report will be published in due course elsewhere.

The outcome of one set of experiments is as follows: it is found that when $q_I = q_{II}$, and q is in the range $0{\cdot}5 > q > 0$ the signal I in the figure is (within the limits of experimental error) as unpleasant as the signal II (although there is a great difference in tone-colour). On comparing the spectra the two criteria are found to differ by less than 10 per cent when t is made zero and at least eight terms are summed.

Now when $q_I = q_{II}$ the spectrum of the signal II is similar to the spectrum of I, except that all the odd terms are doubled in amplitude and the even terms are entirely absent. Thus on summing the terms to derive the criterion, the absence of half of them is made up for by the doubled amplitude of those remaining.

It is important to notice that roughly the same effect would have been obtained if n or n^3 were substituted for n^2 in the equation; that the signals I and II sound equally unpleasant, therefore, provides no direct test of the criterion. However, it does demonstrate that any criterion (such as the total harmonic percentage) which is based upon the summation of terms in $(p_n)^2$, must necessarily fail to correlate with the unpleasantness.

There is some evidence that $\log(C_t)$ may be used to predict the 'rating' of the distortion; thus, if the rating-scale is expressed by a series of numbers such as: 1, 'distortion not perceptible'; 2, 'perceptible with effort'; 3, 'perceptible without effort' and so on, the rating number tends to vary with $\log(C_t)$.

CHEMISTRY

Smoke Emission of Low-Temperature Chars

In a recent communication by Adams, Gaines, Gregory and Pitt[1], the authors make the usual assumption that coal contains a material of character such that it is partly removed, as tar, on heating. I wish to offer an alternative suggestion.

It is generally admitted that a great part of bitumin coal substance has a polymethylene structure.

It is a well-known fact that the early products of the carbonization of coal are ethane, ethylene, hydrogen, methane and tar.

Now in a series of papers summarized and extended by Dr. C. G. Silcocks and myself in two recent papers[2], we show that ethane and ethylene react at temperatures in the region in which low-temperature carbonization is usually effected, thus:

$$C_2H_4 + C_2H_6 = C_4H_8 + H_2 \qquad (1)$$

$$C_2H_4 + C_2H_4 = C_4H_8 \qquad (2)$$

The product, in the presence of excess hydrogen, is converted mainly into methane, and, in the absence of hydrogen, it loses hydrogen and polymerizes, forming tarry bodies. Of the nature of these strange bimolecular reactions I can only say that they appear to be homogeneous *in vitro*.

In a recent communication published in the *Journal of the Institute of Fuel* (April 1957) I suggested that this combination of reactions may account for the formation of methane and tar during the process of low-temperature carbonization of coal and, if this is the case, the formation of tar may continue so long as any methylene structure remains in the coal. *In vitro* the bimolecular reactions (1) and (2) appear to be homogeneous, but what may happen when C_2-hydrocarbon is formed from the methylene structure within the mass of the coal is unpredictable.

The bimolecular reactions (1) and (2) are unique in that propane and propylene behave in no way similarly. But during the pyrolysis of higher hydrocarbons, C_2-hydrocarbons are always formed; then further changes follow as indicated.

In 1938, I communicated to the Faraday Society a paper on the system:

$$\text{carbon} + \text{hydrogen} \rightleftharpoons \text{methane}$$

At temperatures below 700° C. the equilibrium relations appeared to indicate that methane was formed by a reaction represented by:

$$>CH_2 + H_2 \rightleftharpoons CH_4$$

The work was made difficult by the fact that equilibrium was established slowly, and leakage of hydrogen through the walls of the reaction vessel had to be allowed for. By itself I should not have paid much attention to this result, but it falls into line with the other experimental work I have mentioned.

Effect of Carrier Gas on Katharometer Response

In recent communications[1] the relative effects of gases of high and low thermal conductivity on the response of katharometers to the presence of eluted substances have been considered. Several recent publications[2-5] have dealt with this, but a few points can usefully be emphasized.

The classical heat balance of a katharometer is given by[6]:

$$\frac{i^2R}{J} = Ctk_1 + H \qquad (1)$$

where i is the filament current, R its resistance, C a cell constant, k_1 the thermal conductivity of the gas, and t the difference in temperature between the wire and the walls of the cell. H represents the heat lost by a variety of means such as convection, conduction down the leads, radiation and transfer to a flowing gas. This has been passed over by Ray and by Schmauch and Dinerstein but is of great importance, and the last factor particularly is important in katharometer behaviour, as shown by Bohemen and Purnell[2].

The sensitivity of a katharometer is measured in electrical units. Thus, a change $\mathrm{d}t$ in the temperature of the wire produces a change $\mathrm{d}R$ in its resistance and hence a change in potential of $i\mathrm{d}R$ volts. Ignoring H, as above, it can then be shown[3] that:

$$(\mathrm{d}E)_t = \frac{J\alpha Ct^2}{i}\,\mathrm{d}k_1 \text{ (volts)} \qquad (2)$$

where $(\mathrm{d}E)_t$ is the katharometer response at t° C. and α is the temperature coefficient of resistance of the wire.

Whence, from (1):

$$(\mathrm{d}E)_t = \alpha . \frac{i^3R^2}{CJ{k_1}^2}\,\mathrm{d}k_1 \qquad (3)$$

However, also from (1) and (2):

$$(\mathrm{d}E)_t = \alpha\,\frac{(JRt^3)^{1/2}}{(Ck_1)^{1/2}}\,\mathrm{d}k_1 \qquad (4)$$

Equation 4, which has been verified experimentally[3], applies, of course, only to one carrier gas, but is interesting in that should equation 3 be generally true, as argued by Ray, the response of katharometers at constant temperature of the wire is inversely proportional to ${k_1}^{1/2}$, in contrast to the statements both of Ray and of Schmauch and Dinerstein. Furthermore, there is evidence[3] supporting equation 4 which fits the facts of hydrogen and helium systems remarkably well. However, this is purely fortuitous and due to the fact[1] that $\mathrm{d}k_1/\mathrm{d}x$ is approximately equal for these two gases. If the thermal conductivity (k_2) of a diluent is very much less than that of the carrier then $(k_1 - k_2)/k_1$ or $\mathrm{d}k_1/k_1$ should be approximately equal for two carriers. Whence the ratio of helium to hydrogen responses becomes:

$$\frac{(\mathrm{d}E)\mathrm{He}}{(\mathrm{d}E)\mathrm{H}} = \sqrt{\frac{k_1\mathrm{He}}{k_1\mathrm{H}}} \qquad (5)$$

a result which simply does not fit the facts. It has been found necessary to qualify the significance of $(k_1 - k_2)/k_1$ by the introduction of constants only approximately unity, thus: $(b_1k_1 - b_2k_2)/k_1$. I understand that there is theoretical justification for this (Littlewood, A. B., private communication). When considering other carrier gases the importance of H (equation 1) cannot be ignored as it can with hydrogen and helium. This greatly complicates the mathematics, and systems worth studying would be helium in hydrogen and water vapour in both, where k_1 and k_2 are nearly equal but H can be ignored.

A final point not mentioned by Ray is that the temperature of the wire rises when the working substances he uses are eluted in helium, but falls when they are eluted in argon. This has been missed by Schmauch and Dinerstein, who give responses only for substances which cause a rise in the temperatures of the wire with nitrogen. The results are not, therefore, comparable. In any event, the point is a simple one. Helium is obviously much more easily detected by katharometer in nitrogen or argon than in hydrogen.

Use of Katharometers in Gas Chromatography

IN a recent communication[1], Ray attacks the tenet that "the use of hydrogen or helium as the carrier gas in gas chromatography gives the highest sensitivity with a thermal conductivity detector". He derives an equation describing katharometer behaviour from which he infers that the carrier gas with the lowest thermal conductivity will give the highest sensitivity. He concludes that nitrogen, argon, or carbon dioxide will provide greater sensitivity than hydrogen or helium. We wish to point out that the conclusion drawn from this equation does not follow generally, although it may be valid in certain instances. Furthermore, a basic assumption in Ray's derivation is contrary to the usual operating procedure for katharometers.

His equation, $dt/dx = -a(k_1 - k_2)/k_1^2$, states that the sensitivity of the detector, dt/dx, is proportional to the difference between the thermal conductivity of the carrier gas, k_1, and the vapour, k_2, and inversely proportional to the square of the thermal conductivity of the carrier gas. As Ray implies, this function has an arbitrarily large negative value as k_1 approaches zero. He fails to note that it also exhibits a maximum when the thermal conductivity of the carrier gas is twice that of the vapour being analysed.

We have computed values (Table 1) of katharometer sensitivity using this equation and the values of thermal conductivity for various carrier gases and organic vapours given in the International Critical Tables[2] for 0° C. It will be seen that argon provides high sensitivity for methane, low sensitivity for ethylene and again high sensitivity for benzene. This is because in the first instance the thermal conductivity of argon is approximately one-half that of the methane; in the second instance, the thermal conductivities of carrier and vapour are nearly identical, and in the third instance the thermal conductivity of argon is almost exactly twice that of benzene. Thus, the response of the katharometer may be either positive or negative depending on whether the organic vapour being detected has a smaller or larger thermal conductivity than the carrier, and also varies greatly in absolute value. In contrast, helium, the thermal conductivity of which is high relative to organic vapour, gives a nearly constant sensitivity, which permits quantitative estimation of the concentration of each component in a complex mixture.

Table 1. THERMAL DETECTOR SENSITIVITIES RELATIVE TO METHANE IN HELIUM

	Argon ($k = 1·58$)	Nitrogen ($k = 2·28$)	Helium ($k = 13·9$)
Methane ($k = 2·94$)	−9·82	−2·11	1·00
Ethane ($k = 1·80$)	−1·58	1·61	1·11
Ethylene ($k = 1·64$)	−0·44	2·11	1·12
m-Pentane ($k = 1·16$)	2·98	3·86	1·16
Benzene ($k = 0·825$)	5·44	4·91	1·19

Table 2. CONSTANT HOT-WIRE TEMPERATURE

	Argon	Nitrogen	Helium
Methane	−1·09	−0·35	1·00
Ethane	−0·18	+0·27	1·10
Ethylene	−0·05	0·35	1·12
m-Pentane	0·34	0·62	1·15
Benzene	0·59	0·81	1·19

It should also be noted that Ray's equation 1 implies that in all experiments the same current flows in the detector. However, it is common practice to increase the current when using a carrier gas of higher thermal conductivity, so that the difference in temperature between hot wire and cell wall is kept constant. Under these conditions the approximate equation will be $dt/dx = -a(k_2 - k_1)/k_1$.

Relative sensitivities (Table 2) have been computed for this mode of operation. It is clear that helium is eminently superior to either argon or nitrogen. Thus, while it may be true that the use of a carrier gas of thermal conductivity much lower than that of any organic component to be analysed would exceed helium in sensitivity, no gas now available is applicable to the large variety of substances at present being analysed by gas chromatography.

Effect of the Carrier Gas on the Sensitivity of Thermal Conductivity Detectors in Gas Chromatography

IT has recently been suggested[1] that the use of argon or other carrier gases of low thermal conductivity will lead to increased sensitivity of thermal conductivity detectors used in gas chromatography. While this may be so in certain special cases, it is by no means a general effect, and it is the purpose of this communication to point out some of the many disadvantages of carrier gases of low thermal conductivity. The effects we wish to discuss may be illustrated qualitatively by the use of the approximate equation[1] for the variation of filament temperature (t) with composition (x) of the eluted gas.

$$\frac{dt}{dx} = \frac{a(k_1 - k_2)}{k_1^2} \quad (1)$$

where k_1,k_2 are the thermal conductivities of the carrier gas and organic vapour respectively. Substituting the thermal conductivity data from Table 1 in equation 1 leads to the predicted relative sensitivities shown in Table 1. The substances investigated, benzene, *n*-heptane, chloroform, carbon tetrachloride and methyl chloride, would appear from Table 1 to show a higher sensitivity with argon than with helium but ethanol would show a lower sensitivity, and methanol would show a peak reversal compared to ethanol. It should be pointed out that these estimates are only crude approximations since the initial temperature of the detector filament is unknown and is probably considerably higher than 100° C. for our apparatus in which the block temperature is 100° C.

Table 1. THERMAL CONDUCTIVITIES OF GASES AND VAPOURS AT 100° C. (REF. 2)

Substance	k cal. cm.$^{-1}$ sec.$^{-1}$ deg.$^{-1}$	$\frac{k_1 - k_2}{k_1^2} \times 10^2$	
		Helium	Argon
Helium	39·85	—	—
Argon	5·087	—	—
Chloroform	2·333	2·36	+10·64
Carbon tetrachloride	2·048	2·38	+11·74
Methyl chloride	3·841	2·27	+ 4·81
Ethanol	4·99	2·20	+ 0·41
Methanol	5·161	2·18	− 0·28

Ideally, comparison of sensitivities for different carrier gases should be made with constant filament temperature rather than constant current. Such a comparison would lead to different relative sensitivities and generally lower sensitivities for argon relative to helium than those obtained in our experiments. Unfortunately, our experimental arrangement did not allow measurements of potential across the filament and therefore comparisons were made with the same filament current. This does not, however, vitiate our qualitative conclusions.

A Perkin–Elmer *F* column containing 25 per cent by weight of stationary phase was used at 100° C. with a flow-rate of 100 cm.^{3}/min. and a constant filament current of 140 m.amp. Results were obtained with various mixtures using a 'Gow-Mac' four-filament type thermal-conductivity cell as shown in Table 2.

Table 2 shows that the relative responses for various substances are more nearly equal with helium than with argon as carrier. In the first four systems recorded, the mixtures contained equal volumes of the two components. The sign of deflexion is taken relative to the ethanol peak; thus we see that for three of the systems the peaks are in the same direction as ethanol in argon and in the remaining three the peaks are reversed in argon. In fact, the ethanol peak is reversed in argon relative to helium. Secondly, we see that for some mixtures the detector is less sensitive in argon.

Table 2

Mixture	Sensitivity ratio EtOH/x	
	Helium	Argon
MeOH + EtOH	+0·86	+0·63
EtAc + EtOH	+1·19	+9·00
CCl_4 + EtOH	+1·15	−1·11
$CHCl_3$ + EtOH	+1·69	−1·78
CH_3I + EtOH	+0·65	−0·57
CH_3Cl + EtOH	+4·45	+ 126

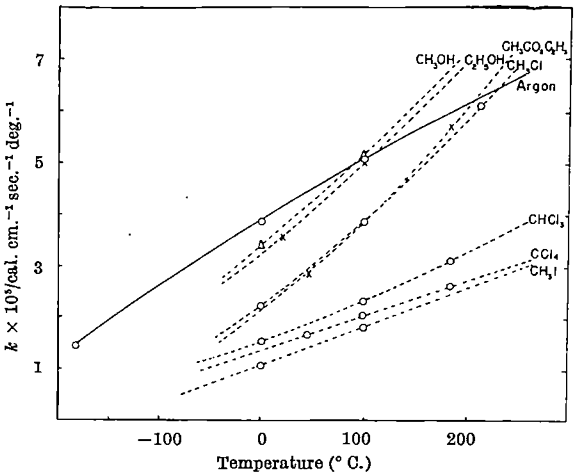

Fig. 1. Thermal conductivities of gases and vapours

If a vapour possessed the same thermal conductivity as the carrier gas at the effective temperature (which is not necessarily the filament or the block temperature), then the detector would be insensitive during the passage of eluted vapour through the conductivity cell. Such is almost the case with methyl chloride with a value of + 126 for the sensitivity ratio in argon shown in Table 2. This affords an approximate method of determining the effective temperature, which from Fig. 1 is around 260° C. Unfortunately there is no such obvious method of deducing the temperature with helium, although the temperature will be lower than in argon for any given current. Comparison with Fig. 1 shows that the sensitivity of systems exhibiting peak reversal in argon correlates with the distance from the argon thermal conductivity line.

The above results confirm the qualitative conclusions drawn from equation 1, that the variation of sensitivity when argon is used as carrier gas is large, varying from large positive sensitivities through zero to large negative sensitivities, whereas the sensitivity when helium is used as carrier gas is more nearly constant for a range of materials. Since gas chromatography is very often used to analyse for materials the nature of which is unknown and since the data on thermal conductivities are sparse, it would seem that helium or hydrogen is a better carrier gas to use for general purposes and that argon or other gases of low thermal conductivity should be used only in cases where calibration has shown that the ultimate sensitivity is substantially higher.

Isotopic Composition of Boron and its Atomic Weight

After an extensive investigation, we conclude that a boron-11/boron-10 ratio of 4·00 (that is, 80/20) approaches the true natural abundance ratio much more closely than the presently 'accepted' value of 4·31 (81·17/18·83). The latter figure is based on a mass spectrometric investigation of boron trifluoride[1], a notoriously troublesome compound, in view of its adsorption characteristics resulting in instrumental 'memory'. Since publication of that work a number of attempts to verify the abundance ratio from boron trifluoride have resulted in a wide range of values.

On the other hand, abundance ratios calculated by various investigators from mass spectra of boron hydrides have been highly consistent, yielding ratios of approximately 4·00. Lest it be argued that this lower value may be peculiar to boron hydrides, we would like to point out that recent work in this laboratory with other compounds (for example, trimethylboroxine) has yielded the same ratio.

We therefore propose that in the future it would be far more reasonable to use the ratio 4·00 (80/20) to represent the natural isotopic abundance of boron. This would require in addition a revision of the atomic weight from 10·82 to 10·811, a change which seems well within the range of experimental error of earlier investigators[2].

BIOCHEMISTRY

Synthesis of Oxytocin by the Nitrophenyl Ester Method

After the completion of work on the degration of oxytocin[1], this compound was synthesized in this laboratory[2]. Since that time several other synthetic methods leading to biologically active solutions of the crude hormone have been reported[3]. Recently, an improved synthesis of oxytocin was elaborated[4] by us. All these syntheses of oxytocin have the common feature of linking peptides together. It is well known, however, that formation of the peptide bond with a protected peptide as the acid component can lead to racemization[5], the extent of which depends on the components, the conditions and the method. No racemization was observed with the use of the azide method[6]. Nevertheless, the latter procedure can involve the formation of by-products other than diastereoisomers. To avoid racemization it is possible to take advantage of the protecting groups, for example, the carbobenzoxy group, which protects the amino-acid acylated by it not only against unwanted acylation but also against racemization. This protection is effective only if the carbobenzoxy group is joined to the amino-acid, the carboxyl group of which takes part in the peptide bond-forming reaction. Therefore it becomes necessary to start the synthesis with the C-terminal amino-acid, to link to it the next (protected) amino-acid, to remove the protecting group from the resulting dipeptide derivative, to couple to the free amino component thus formed the third (protected) amino-acid, etc. This manner of peptide-chain synthesis is practicable only if the method used for the formation of the peptide bond is unambiguous, leads to only one peptide, and gives high yields. All the mixed anhydride methods were eliminated as they usually

* The O-benzyl group is removed from the tyrosine residue by hydrobromic acid in acetic acid. It is not necessary in the next step.

Fig. 1

lead to two acylation products, the separation of which, for example by crystallization, can be difficult, especially in cases of peptides with several amino-acids. After the elimination of many other unsuitable possibilities the nitrophenyl esters of acylamino-acids were found to be suitable for this purpose.

The use of acylamino-acid nitrophenyl esters in peptide synthesis was suggested and applied earlier by one of us (M. B.)[7]. An improved method for the preparation of such esters was proposed later by Schwyzer and his co-workers[8]. Recently, however, di*cyclo*hexylcarbodiimide was used by Elliot and Russel[9] for the esterification of acylamino-acids with *p*-nitrophenol and we have found this procedure to be very convenient, giving high yields of pure products. For the synthesis of oxytocin, the *p*-nitrophenyl esters of cbz-L-leucine, cbz-L-proline, S-benzyl-N-cbz-L-cysteine, cbz-L-asparagine, cbz-L-glutamine, cbz-L-*iso*leucine and O-benzyl-N-cbz-L-tyrosine were prepared. All these esters are stable, optically pure compounds with excellent crystallization properties. The synthesis of oxytocin with the aid of these esters is outlined in Fig. 1.

Lengthening the already existing chain by one amino-acid was achieved in very satisfactory yields, usually 90–100 per cent of the theoretical amount. The protected peptides were obtained in reasonable purity and gave good analyses even without further purification. Most of the intermediates were readily obtained in crystalline form. The purity of the protected nonapeptide is best demonstrated by the fact that on removal of the protecting groups by sodium in liquid ammonia, followed by aeration, oxytocin was formed in 78 per cent yield from it. Experimental details of this work will be presented elsewhere.

We believe that the method of synthesis outlined here may be useful both for structural proof and also for practical preparation of larger peptides of biological interest.

This work was supported in part by a grant from the National Heart Institute, U.S. Public Health Service, grant No. *H*-1675.

Effect of Hydrolysis by Papain on the Combining Sites of an Antibody

PORTER[1] recently found that proteolysis of each of several different rabbit antiprotein antibodies with papain yielded three chromatographically separable fractions. Two of the fractions retained the capacity to combine with antigen, as shown by their ability to block specific precipitation, but would not form specific precipitates. The results indicated that the bivalent antibody molecule had in each case been split into two univalent fragments which retained specific activity and a third fragment lacking a combining site.

The use of anti-hapten antibody permits determinations of the specific binding of hapten, which provide a direct measure of the effect of a given treatment on the average equilibrium constant and the number of combining sites. In contrast with the precipitin reaction, quantitative measurements can be made with only one active site present on a molecule or fragment. With this technique we have found that hydrolysis of the antibody molecule by crystalline papain into fragments about one-third the original size has little effect on the capacity to bind hapten; that is, the combining sites in the degraded molecules are almost completely intact.

Experiments were done with a γ-globulin fraction of rabbit anti-*p*-azobenzoate antibody (containing 6·1 per cent of antibody specifically precipitable by an ovalbumin-*p*-azobenzoate test antigen[2]) and also with specifically purified antibody (73 per cent precipitable). Binding measurements were carried out by equilibrium dialysis with radioactive *p*-iodobenzoate having a radiochemical purity greater than 99 per cent. Methods used for the preparation of specifically purified antibody and for equilibrium dialysis have been described in detail[2,3].

Preparations of γ-globulins were made by the procedure of Kekwick[4] and were found to migrate as a single peak (6·5–7 S.) in the ultracentrifuge. Papain (twice crystallized) was purchased from the Worthington Company.

Antibody or normal γ-globulin preparations were treated at *p*H 7 with the amounts of papain and in the buffer indicated in Table 1. Mixtures were allowed to stand for 18–20 hr. at 37° C., then at room temperature. During the next 6 hr., measurements were made in the ultracentrifuge; equilibrium dialysis was then carried out with portions of the same samples.

Results are given in Table 1. For the samples treated with papain the $S_{20,w}$ values fall in a narrow range (3·4–3·6 S.) as compared with 6·5–7·0 S. for the untreated antibody γ-globulin or normal γ-globulin. None of the faster-moving material (6·5–7 S.) remained in any of the preparations treated with papain. In the case of antibody γ-globulin the amount of papain used was varied by a factor of 10. Thus the use of more enzyme resulted in little change in the apparent sedimentation constant, although the fraction of dialysable protein increased from 13 per cent (sample 4*A*) to 42 per cent (sample 6*A*). The $S_{20,w}$ values for the hydrolysed samples are in close agreement with those found by Porter[1], who observed a single peak with $S_{20,w} = 3{\cdot}5$, and a molecular weight of 55,000–60,000 (as compared with 160,000 for untreated antibody). The small amounts of papain ($S \simeq 2{\cdot}4$)[5] used did not appear in the sedimentation patterns as a separate peak.

Table 1. Effect of Crystalline Papain on Rabbit Anti-*p*-Azobenzoate Antibody*

Experiment No.	Sample	Papain used (mgm.)	$S_{20,w}$†	Conc. labelled *p*-iodobenzoate bound‡ ($M \times 10^{6}$)
1*A*	Normal γ-globulin	0	6·7	—
2*A*	Normal γ-globulin	16·5	3·4	0·06 ± 0·03
3*A*	Antibody γ-globulin	0	6·5	2·91 ± 0·07
4*A*	Antibody γ-globulin	1·7	3·6	2·66 ± 0·07
5*A*	Antibody γ-globulin	4·2	3·5	2·58 ± 0·03
6*A*	Antibody γ-globulin	16·5	3·5	2·17 ± 0·04
1*B*	Specifically purified antibody	0	7·0	5·07 ± 0·03
2*B*	Specifically purified antibody	0·5	3·5	4·75 ± 0·06

* Hydrolysis at 37° C. for 18–20 hr.; *p*H 7·0. Buffer contained sodium salts of phosphate (0·1 *M*), versene (0·002 *M*) and cysteine (0·01 *M*). 200 mgm. γ-globulin (series *A*) or 8 mgm. specifically purified antibody (series *B*) present in each mixture. Total volume 10 ml. in series *A*, 1·4 ml. in *B*. Papain added as an aqueous solution in two equal portions, at zero time and after 1½ hr.

† Sedimentation at 59,780 r.p.m. in 'Spinco' model *E* ultracentrifuge. Concentration of protein in sedimentation of series *A*, 10 mgm./ml. except for sample 1*A* (15 mgm./ml.); concentration in series *B*, 5·8 mgm./ml.

‡ Equilibrium dialysis in triplicate at 5·0 ± 0·1° C. with mean deviations shown. Free concentration of radioactive *p*-iodobenzoate after equilibration; in series *A*, $2·74 \times 10^{-6}$ *M*; in series *B*, $4·49 \times 10^{-6}$ *M*. Maximum deviation in free concentration in either series, 3 per cent.

In contrast with the large decrease in molecular size are the small changes in binding capacity. For samples 2*B* or 4*A*, which exhibited a single peak at 3·5 or 3·6 S., the concentration of hapten bound was more than 90 per cent as large as that for the corresponding untreated antibody preparation at the same free hapten concentration. Since the free hapten concentration was held constant, the results indicate that the decrease in the average binding constant or in the total number of binding sites was less than 10 per cent[6]. The use of larger amounts of papain resulted in somewhat greater decreases in binding capacity (up to 25 per cent) but most of the combining sites were evidently still intact.

Treatment with papain resulted in each case in complete loss of ability to precipitate with the ovalbumin–*p*-azobenzoate test antigen, as shown by tests made with a wide range of antigen concentrations. Control experiments, in which the papain was inactivated by treatment with 0·01 *M* ferricyanide prior to addition of antigen, showed that this failure to precipitate was due to the action of papain on the antibody (rather than on the antigen).

The results indicate that the rabbit antibody molecule can be degraded to a non-precipitating form of relatively low molecular weight with little effect on the specific combining sites. It appears also that measurements of binding capacity provide a convenient quantitative method for investigating the properties of these apparently univalent antibody fragments.

Regeneration of Cellulose Acetate Membranes used for Zone Electrophoresis

The method described by Kohn[1] for the analysis of serum proteins by zone electrophoresis on strips of cellulose acetate membrane has been proved to be of great value. The development of this technique, as a micro-electrophoretic method[2], has emphasized the importance of cellulose acetate as a stabilizing medium. The sheets of cellulose acetate are relatively expensive compared with filter paper, and their higher cost may deter workers from using this excellent material. It has been found that the cellulose acetate membrane strip may be used several times after suitable treatment by the method to be described.

On completion of an analysis the used strip of cellulose acetate membrane with the stained bands of protein is placed in a shallow dish containing 200 ml. of buffer at *p*H 8·6 (veronal, sodium bicarbonate or sodium borate, ionic strength 0·05–0·1) to which is added 2·0–4·0 ml. trypsin solution. The trypsin solution contains 64 units of trypsin per ml. and is standardized by the method described by Coles[3]. The digestion of the protein occurs rapidly for quantities of protein in the range 100–200 μgm. and is complete at 37–39° C. in 2 hr.; but the digestion of 700 μgm. of protein, used with longer and wider strips, is not complete in 2 hr. and sometimes required periods of 16 hr. The longer digestion period is necessary to regenerate strips of cellulose acetate membrane which have been stored in a dry condition for some months after staining. After digestion of the protein, the cellulose acetate membrane strip is washed with distilled water and re-equilibrated in the buffer solution used for the electrophoretic separation. It is then ready for further use.

The cellulose acetate is quite stable under the conditions of regeneration: and in one instance a membrane strip has been regenerated four times without any apparent deterioration; this strip was dyed with lysamine green, bromphenol blue, nigrosine and finally bromphenol blue again for its use on the first, second, third and fourth occasions respectively.

In one instance 700 μgm. of serum protein had been separated into its component fractions by electrophoresis on a cellulose acetate membrane in a buffer solution to which copper sulphate had been added. The regeneration process, performed several months after the membrane had been dried, was not complete. The globulin fractions were digested by the trypsin; but the large stain corresponding to the albumin fraction was not removed. In this case, after treatment with trypsin, the membrane was washed with distilled water, then twice with ethyl alcohol and was finally equilibrated against benzene. The membrane appeared translucent and all traces of dye disappeared. The membrane was then washed with ethyl alcohol, followed by distilled water and finally re-equilibrated against the buffer solution unchanged. Its performance in use after regeneration was quite normal, and another sample of normal serum protein was fractionated successfully.

Amperometric Determination of Sulphydryl Content of Blood and Tissues

THE total, non-protein and protein sulphydryl contents of biological materials can be determined by using two different analytical procedures: one for the determination of total sulphydryl (protein sulphydryl + non-protein sulphydryl) values and the other for the determination of non-protein sulphydryl values. The protein sulphydryl values are obtained by subtracting the non-protein sulphydryl values from the protein sulphydryl values. Most of the available methods, however, are often complicated, time-consuming and more or less non-specific. In an earlier communication[1] it was reported from this laboratory that, with a little modification, the amperometric method of Benesch, Lardy and Benesch[2] can be used for the specific determination of the total sulphydryl content of biological materials. It has since been observed that the method can be adapted for the non-protein sulphydryl determinations in the same materials. Thus it is possible to use a simple, specific and rapid method for the determination of all the three sulphydryl fractions in biological materials.

Table 1. CONCENTRATION OF TOTAL, NON-PROTEIN AND PROTEIN SULPHYDRYL IN RAT BLOOD AND TISSUES

The means of results with number of determinations in parentheses are given. The results are expressed in mgm./100 gm. for wet tissues and mgm./100 ml. for blood

Sample analysed	Total sulphydryl	Non-protein sulphydryl	Protein sulphydryl*
Whole blood	91·4 (8) 83·6–100·0	2·9 (4) 2·5–3·3	88·5
Liver	55·4 (7) 51·4–58·8	26·4 (4) 23·4–32·0	29·0
Kidney	48·3 (3) 45·0–53·0	11·3 (4) 8·7–13·1	37·0
Heart	31·2 (3) 28·0–33·0	7·2 (4) 6·8–7·9	24·0
Pancreas	25·4 (6) 20·0–30·4	6·7 (4) 6·5–6·9	18·7

* These values were obtained by subtracting the means of non-protein sulphydryl values from the means of total sulphydryl values.

The amperometric titration apparatus, with the exception of the platinum electrode, is assembled according to Benesch, Lardy and Benesch. For the construction of the platinum electrode, four strands (each 35 mm. long and 0·5 mm. diam.) of tightly twisted platinum wires are sealed in a soft-glass tubing in such a way that 15–20 mm. of the bare metal protrudes beyond the glass. The projecting wires are bent laterally into a U-shape. This electrode, in contrast to that used by others[2], greatly increases the sensitivity of the apparatus. For total sulphydryl determinations tissue homogenates and hæmolysed blood samples[1] are used. For non-protein sulphydryl determinations, sulphosalicylic acid (2·5 per cent solution) extracts of blood and tissues prepared according to the method of Benesch and Benesch[3] are used. Tissue homogenates (1–2 ml.), whole blood (0·1 ml. hæmolysed with 1 ml. of de-ionized distilled water), and sulphosalicylic acid extracts (1–5 ml.) of blood and tissues are titrated with 0·002 *M* silver nitrate in *tris* (hydroxymethyl) aminomethane buffer[2], *p*H 7·4. Each increment (0·1–0·2 ml.) of silver nitrate is added at 1-min. intervals and the micro-ammeter reading is taken at 55 sec. after each addition. It is essential to neutralize the sulphosalicylic acid extracts before addition to the buffer. The neutralization is carried out with 0·8 *M* sodium bicarbonate, the amount being determined in a separate titration using methyl orange as an indicator. During the titration of tissue homogenates pieces of connective tissue may adhere to the platinum electrode and cause mechanical interference with current readings. This is easily eliminated by first rotating the electrode for a few minutes in the buffer containing the homogenate (before the addition of silver nitrate) and then removing the adhering pieces from the electrode. To increase the specificity of the method a 'blank' titration is carried out with each estimation, using an excess of a 0·001 *M* solution of *p*-chloromercuribenzoate in 0·05 *N* sodium hydroxide. The technique of the 'blank' titration is very similar to those used by other workers[4,5]. Where x ml. of 0·002 *M* silver nitrate is required for a titration, $2x + 0{\cdot}1$ ml. of 0·001 *M* *p*-chloromercuribenzoate solution is added to block the sulphydryl groups. *p*-Chloromercuribenzoate is allowed to react for 5 min. before the titration. The final volume of the titration mixture, including the *p*-chloromercuribenzoate solution, is kept at 30 ml. Calculation: 1 ml. of 0·002 *M* silver nitrate ≡ 0·066 mgm. of sulphydryl.

The results of sulphydryl determinations, using the above method, in blood and tissues of rats (200–350 gm., both male and female) are summarized in Table 1.

I wish to thank Prof. F. C. Happold for giving the laboratory facilities, and the University of Leeds for an Imperial Chemical Industries Fellowship.

Selenite as a Relatively Weak Inhibitor of some Sulphydryl Enzymes

CONTINUING our studies on the oxidation of sulphydryl compounds[1], we found that selenite was a very active catalyst for the oxidation of cysteine, glutathione, dihydrolipoic acid, and coenzyme *A*. For the oxidation of glutathione, selenite was a far better catalyst than cupric chloride, the most active catalyst known previously[2]. Selenite is poisonous to animals but it is also claimed that selenium is an essential element. Selenium poisoning is an important unsolved problem: the toxic symptoms are complex and the mechanism of the poisoning is still obscure. Some investigators[3,4] believe that selenium compounds exert their toxic effect through interference with certain enzyme systems in the living organism, particularly through mercaptide formation with sulphydryl enzymes. However, most studies on enzyme inactivation had been done with tissue homogenates or yeast cells; and further information on the reaction of selenium salts with purified enzymes seemed desirable. The present communication reports the results of a study of the comparative inhibition of six well-known sulphydryl enzymes by selenite, cupric chloride, and *p*-chloromercuribenzoate.

Table 1. INHIBITION OF SULPHYDRYL ENZYMES

Inhibitor	Concentration (M)	Inhibition (per cent)					
		Alcohol dehydrogenase	Aldolase	D-amino-acid oxidase	β-Amylase	Lactic dehydrogenase	Urease
Selenite	0·01	48	29	—	—	—	—
	0·001	3	1	60	62	0	49
	0·0001	0	0	54	40	0	6
Cupric chloride	0·001	100	100	100	91	100	89
	0·0001	100	98	44	57	99	10
	0·00001	75	2	—	—	0	—
p-Chloromercuribenzoate	0·001	100	100	100	100	100	100
	0·0001	100	50	66	91	100	96

Yeast alcohol dehydrogenase (2× crystallized), muscle aldolase (5× crystallized), and kidney D-amino-acid oxidase were purchased from the Worthington Biochemical Corp.; muscle lactic dehydrogenase (crystallized) and urease (type V, special purity) from Sigma Chemical Co.; and barley β-amylase from Nutritional Biochemicals Corp.

The activities of alcohol dehydrogenase, aldolase, D-amino-acid oxidase, lactic dehydrogenase, urease, and β-amylase were measured by the methods of Racker[5], Swenson and Boyer[6], Frisell and Hellerman[7], Mehler *et al.*[8], Krebs and Henseleit[9], and Bernfeld[10], respectively. For the inhibition tests, the enzyme was incubated at room temperature with the inhibitor for at least 30 min. before determination of the activity.

The results in Table 1 show that, as compared with cupric chloride and p-chloromercuribenzoate, selenite is a rather weak inhibitor for the enzymes studied.

Lethal doses of selenite for several mammalian species are in the range of 1–15 mgm./kgm. body-weight[3]. In view of the fact that selenite is toxic in such small quantities, it does not seem possible that the effect is the result of mercaptide formation with sulphydryl compounds, such as glutathione and sulphydryl enzymes, *in vivo*. Also, from the results of our present studies, it appears unlikely that selenium toxicity is a result of direct inhibition of enzymes. It is more likely that the toxicity may be explained by the selenium-catalysed oxidation of such co-factors as glutathione, coenzyme A, and dihydrolipoic acid, and the resulting disturbances in intermediary metabolism.

Part of this work was done at the University of California, Davis, and the advice of Prof. A. L. Tappel is gratefully acknowledged.

Labelled Keto-Acids in Duck Blood incubated *in vitro* with $NaH^{14}CO_3$

THE ability of duck blood rich in reticulocytes to incorporate *in vitro* carbon-14 from $NaH^{14}CO_3$ has been previously investigated[1]. Separately we have demonstrated incorporation into globin, hæm and stroma. The widespread incorporation suggested that the first products of carboxylation belonged to a pool from which all the substances we examined would be synthesized. This communication is concerned with an attempt to identify some labelled precursors (pyruvic and α-ketoglutaric acids).

45 ml. of duck blood were incubated for 18 hr. as previously described[1]. The plasma was separated from red cells by centrifuging. The plasma proteins were precipitated with 5 per cent metaphosphoric acid (4 ml. for 1 ml. of plasma) and discarded. The keto-acids were isolated from the supernatant as 2 : 4-dinitrophenylhydrazones[2], which were separated by paper chromatography (Whatman No. 1; *iso*-butanol, ammonia, 95 per cent ethyl alcohol, 70 : 20 : 10, v/v/v).

The 2 : 4-dinitrophenylhydrazones of pyruvic and α-ketoglutaric acids and an unidentified substance (R_F, 0) were eluted from the paper with 2 N sodium hydroxide. The eluate was acidified with hydrochloric acid and extracted with ethyl ether. After evaporation of the ether, the substances extracted were assayed for radioactivity by the method previously described[3].

In Table 1 the R_F of 2 : 4-phenylhydrazones of pyruvic and α-ketoglutaric acids and the specific activities of pyruvic and α-ketoglutaric acids are shown. The specific activity of the unidentified substance was 7,500 disintegrations/min./mgm. carbon. No attempt has yet been made to identify it.

Table 1

Material	Pyruvic acid	α-Ketoglutaric acid
Specific activity (dis./min./mgm. C)	1,820 ± 40	1,790 ± 50
R_F of 2 : 4-dinitrophenylhydrazone	0·38 (isomer 1) 0·58 (isomer 2)	0·13

The presence of labelled α-ketoglutaric acid seems to suggest that the Krebs cycle is effective in carbon dioxide fixation by duck blood *in vitro*. The labelled pyruvic acid also seems to be formed from the Krebs cycle acids (that is, oxalacetic acid). Moreover, labelled pyruvic acid could be formed via another pathway:

$$\begin{aligned}
&\text{ribulose-5-phosphate} \xrightarrow{CO_2} \text{6-phosphogluconate}\\
&\text{6-phosphogluconate} \longrightarrow \text{glucose-6-phosphate}\\
&\text{glucose-6-phosphate} \longrightarrow \text{2 pyruvic acid}
\end{aligned}$$

The incorporation of carbon dioxide by certain normal and tumour cells (but not by rabbit erythrocytes) in ribulose-5-phosphate was demonstrated by Baron *et al.*[4].

As succinic acid is formed via α-ketoglutaric acid in the Krebs cycle, and because succinic acid is a precursor of hæm[5], the hæm should also be labelled after incubation *in vitro* of duck blood with $NaH^{14}CO_3$.

Experiments in progress suggest that only part of the carbon-14 activity found in globin is due to amino-acids formed by transamination from α-ketoglutaric, oxalacetic and pyruvic acids. Indeed, arginine is also labelled.

Purification of a Toxic Phytohæmagglutinin from Black Beans (*Phaseolus vulgaris*)

Beans, like other seeds of the Leguminosae, contain some proteins of remarkable biological activity. For many years a bean phytohæmagglutinin has been known[1,2]. Rigas and Osgood[3] recently described two different factors with hæmagglutinating properties. Other authors[4,5] have observed toxic effects in animals fed with raw beans or with certain preparations obtained by extracting bean meal. The hæmagglutinin factors prepared according to the original method[3] do not seem to be responsible for the toxic effect of raw beans, as they have only slightly toxic properties. Experiments carried out by one of us (W. J.) have also established the toxicity of beans that cannot be ascribed to the trypsin inhibitor (another protein) described by Bowman[6]. We therefore undertook to isolate the toxic components of beans in order to obtain further information about their properties.

Finely ground black beans (*Phaseolus vulgaris*) are extracted with 5 parts (w/v) of a solution of 1 per cent sodium chloride. By dialysing the filtered extract against water a large amount of inactive material is precipitated. Almost the whole activity is obtained by saturating the supernatant solution with ammonium sulphate. Different active fractions are prepared by saturating fractionally the redissolved precipitate with the same salt.

The main active fraction is obtained by precipitation between 55 and 70 per cent saturation of the redissolved, dialysed crude precipitate which has been previously adjusted to *p*H 6·0. After the precipitating and redissolving procedures have been repeated three times a highly purified protein is obtained which proves to be at least 90 per cent pure as revealed by electrophoresis and ultracentrifugation. The electrophoretic mobility, determined with the 'Spinco' apparatus model *H*, is $8·89 \times 10^{-5}$ cm.²/volt/sec. for a 0·9 per cent solution in barbiturate buffer of *p*H 8·6 and ionic strength 0·1. The isoelectric point should lie between *p*H 4 and 5. The sedimentation constant S_{20} for a 0·6 per cent solution in the same buffer was $5·9 \times 10^{-13}$ ('Spinco' ultracentrifuge model *E*). The protein, for which we propose the name 'phaseolotoxin *A*', is soluble in water, in 1 per cent sodium chloride solution and is precipitated by 30 per cent cold alcohol. It contains 13·5 per cent nitrogen (Kjeldahl) and 5·0 per cent reducing groups as determined by a modified Somogyi–Nelson method and calculated for glucose. These values relate to air-dried preparations.

Table 1. Physical and Biological Properties of Bean Fractions

Fraction	Electrophoretical mobility (cm.²/V./sec. × 10⁵)	Sedimentation constant ($S_{20} \times 10^{13}$)	Agglutinating activity (*c*) (μgm./ml.)	Toxic activity :	
				Dose (mgm./kgm.)	Mortality (*d*)
Phaseolotoxin *A*	8·89 (*a*)	5·9 (*a*)	3·0	50 60 100	15/2 6/5 9/9
Phaseolotoxin *A* after treatment by stroma	—	—	∞	100	4/0
Phaseolotoxin *A* heated to 80° C.	—	—	6·0	125	7/3
Fraction *B*	24·5 (*a*) 28·5 (*a*) 1·04 (*a*) 4·35 (*b*) 5·79 (*b*)	2·3 (*a*) 6·6 (*a*) 9·7 (*a*) 2·3 (*b*) 6·5 (*b*) 10·6 (*b*) 18·0 (*b*)	4·0	150 200	5/2 5/3

(*a*) Barbiturate buffer, *p*H 8·6; μ 0·1. (*b*) Phosphate buffer, *p*H 6·5; μ 0·1. (*c*) Minimum amount of toxin which gives positive results. (*d*) Toxin in mgm./kgm. mouse: number of animals used for the experiment/number of animals which died after injection.

Saturating the supernatant solution obtained after separating phaseolotoxin *A* by filtration yields another active fraction. The yield of this so-called 'fraction *B*' is low and not uniform. Even when precipitated three times it consists of three main components, as revealed by electrophoretic and centrifugation experiments. Among these no compound with the physical properties of phaseolotoxin *A* could be found.

The hæmagglutinating activity was determined with 0·25 per cent suspensions of washed sheep or mice erythrocytes in saline. 1·0 ml. of this suspension is mixed with 1·0 ml. of the active preparations obtained from beans in adequate dilutions and incubated at 37° C. for 30 min. and then centrifuged at 2,500 r.p.m. in a common laboratory centrifuge. The agglutination test is positive when the erythrocytes are not suspended by shaking.

Toxicity was studied in adult white mice after intraperitoneal injection of adequate dilutions of the preparations. The results of these experiments are shown in Table 1.

There are striking differences between phaseolotoxin *A* and the fraction *B*. These fractions have about the same agglutinating activity, but fraction *B* is at least three times less toxic. Therefore it may be assumed that black beans contain more than one toxic compound. Fraction *B*, different from phaseolotoxin *A* in its physical properties, also shows biological differences, and because of its relatively low toxicity and physical properties it resembles more the phytohæmagglutinin described by Rigas and Osgood[3].

Phaseolotoxin *A* proved to be a single component as revealed by the physical investigations, and these results suggest that hæmagglutinating and toxic properties are due to the same protein. This suggestion is strengthened by two other experiments. When a solution of 50 mgm. of the toxin is incubated for 30 min. at 37° C. with a suspension of 100 mgm. of human erythrocyte stroma in saline[7] the toxin is completely absorbed and after centrifugation the supernatant contains neither agglutinating nor toxic activity. Moreover, when a saline solution of phaseolotoxin *A* in a concentration of 25 mgm./ml. is heated to 80° C. for 60 min. the activities are not completely destroyed, although the solution becomes milkily turbid due to partial denaturation and precipitation. Hæmagglutinating and toxic activity, however, are reduced to the same extent, namely, to about 50 per cent. Boiling for 30 min. uniformly abolishes both activities completely.

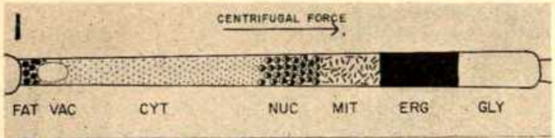
CELL PHYSIOLOGY

Nuclear Origin of Ribonucleic Acid

LIVING hyphæ of *Neurospora crassa* were centrifuged and their contents stratified in distinct layers. Starting at the centrifugal end, the layers were as follows (Fig. 1): glycogen, ergastoplasm (microsomes), mitochondria, nuclei, 'supernatant' cytoplasm, vacuoles and fat. Each fraction could be identified by cytochemical reactions. It was found that most of the cytoplasmic ribonucleic acid resided in ergastoplasm, some in mitochondria, and none was detectable in the 'supernatant'. Nuclei were relatively poor in ribonucleic acid.



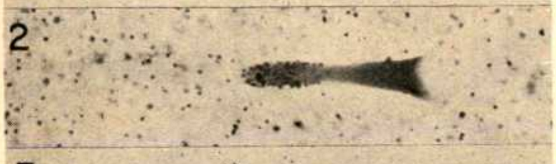


Fig. 1. Schematic presentation of a centrifuged hypha of *Neurospora*. *FAT*, fat; *VAC*, vacuole; *CYT*, 'supernatant' cytoplasm; *NUC*, nuclei; *MIT*, mitochondria; *ERG*, ergastoplasm (microsomes); *GLY*, glycogen. Centrifugal direction is to the right in all figures

Fig. 2. Autoradiograph of a centrifuged hypha fed tritiated uridine for 1 min. prior to centrifugation, stained with hæmalum. β-tracks in the nuclear layer; deeply stained layer, free of tracks, is ergastoplasm; glycogen and 'supernatant' not stained

Fig. 3. Autoradiograph of a centrifuged hypha fed tritiated uridine for 1 min. and unlabelled uridine for 1 hr., prior to centrifugation. β-tracks densest in ergastoplasm, less dense in nuclei and mitochondria; no significant increase of tracks over background in glycogen and 'supernatant'

The fact that nuclei became clearly separated from the cytoplasmic ribonucleic acid enabled us to localize the site of formation of ribonucleic acid. Mycelium, in its active growth phase, was fed tritiated uridine (uridine-5,6-^{3}H, 640 mc. per m.mole, 100 μgm./ml.) for given times, centrifuged and fixed. The mycelium was then washed in cold 5 per cent trichloracetic acid so that only nucleosides which were incorporated into ribonucleic acid remained. The preparation was mounted on a slide and covered with photographic emulsion[1]. After exposure and development, the autoradiographs showed tracks of β-decay at the sites of uptake of the precursor.

At short feeding times, from 1 to 4 min., the label appeared only in the nuclear fraction (Fig. 2). After 4 min., more and more label was found in cytoplasmic ribonucleic acid. In 1 hr., ergastoplasm was labelled much more heavily than the nuclei (Fig. 3), and some activity was found also in mitochondria, while the 'supernatant' remained virtually inactive. In brief, the distribution of the label became roughly proportional to the relative content of ribonucleic acid in the different fractions. When tritiated uridine was fed for 1 min. only and then washed out and replaced with an excess of non-labelled uridine, the label again appeared first in nuclei, to appear in the ergastoplasm only after several minutes. The labelling of ergastoplasm increased with time at the expense of nuclear label.

These results demonstrate that all the cellular ribonucleic acid is formed in nuclei and that it migrates into the cytoplasm later. Previous work of several investigators indicated that ribonucleic acid originated in nuclei[2] and the present experiments substantiate this hypothesis. These findings suggest that ribonucleic acid is a direct product of gene action. Ribonucleic acid is formed in nuclei, the seat of chromosomes and genes; it migrates into the cytoplasm; and it is required for the synthesis of proteins. A detailed report of this investigation will be published elsewhere.

Hæmoglobin and 'Apparent Protein' in the Human Red Cell

THE concentration C_{Hb} of hæmoglobin is conventionally measured by dividing the hæmoglobin in gm. per cent by the fractional concentration ρ, allowance being made for incomplete packing in the hæmatocrit tube. If a high-speed hæmatocrit is used, ρ can be found with an error of about ± 1 per cent, and the hæmoglobin concentration can be measured by the cyanmethæmoglobin method with an error of about the same magnitude.

An independent method measures the concentration C_i in gm. per cent of what can be called 'apparent protein'; this includes hæmoglobin, colourless hæmoglobin precursors, lipoproteins, and 'stromatin'. Other substances contribute to a very small extent. The measurements of C_i are made with an *AO*-Baker interference microscope and with monochromatic green light, the red cells being turned into spheres by being suspended in a non-hæmolytic lecithin (Polanyi, personal communication). The equations are (Barer[1])

$$\mu = \frac{\theta\lambda}{360\,t} + n$$

and

$$C = \frac{\mu - n}{\alpha}$$

where θ is the phase retardation in degrees, λ the wave-length in the same dimensions as t, the cell thickness (equal to the diameter) of the spherical red cell, n the refractive index of the medium surrounding the cell, and α a constant called the specific refractive increment. Because the concentration of hæmoglobin in the red cell is so high, α has to be determined experimentally with a calibrated Nichols refractometer[2]. The calibration can be made with water ($n = 1{\cdot}333$), acetone ($n = 1{\cdot}3592$), and n-butyl alcohol ($n = 1{\cdot}3991$), all at 20° C.

About 1 ml. of normal or hypochromic blood is packed at high centrifugal force ($2 \times 10^4 g$), the supernatant column of plasma is removed, and the cells in the red cell column are hæmolysed by freezing and thawing several times; the hæmolysed sample is then spun in a high-speed centrifuge in order to free it as much as possible from ghosts, etc. The almost ghost-free supernatant column is removed, and its hæmoglobin concentration is found by the cyanmethæmoglobin method. Its refractive index is found with the Nichols refractometer by reference to the calibration curve. A graph is prepared in which refractive index is plotted against hæmoglobin concentration, straight lines being drawn for refractive index increments of 0·0020, 0·0018, etc. A vertical line is drawn through the determined hæmoglobin concentration, and a horizontal line is drawn through the determined refractive index. These two lines intersect at a point which corresponds to a value of the refractive index increment α. If the same experiment is repeated by determining the refractive index of the sample diluted with water in powers of 2, it is clear that the specific refractive increment is virtually constant with increasing hæmoglobin concentration, being essentially the same ($\alpha = 0{\cdot}0019 \pm 0{\cdot}0002$) when the hæmoglobin is dilute as when it is as concentrated as 30 per cent. It is a pleasure to thank Dr. H. G. Davies for telling me that this value of α is correct in his experience.

The mean value of C_{Hb} in normal males is $30{\cdot}1 \pm 0{\cdot}32$ gm. per cent. The value of C_i found by the refractometer is 33·28 gm. per cent in normal males, that is, about 10 per cent greater if C_{Hb} is considered as 100. It is inconceivable that this amount of 'apparent protein, not hæmoglobin' could be held in a surface ultrastructure of a thickness such as has been proposed, for, if it were, the ultrastructure, *dry*, would have to be about 1000 A. thick. No such value has been suggested, and so at least two-thirds of the 'apparent protein, not hæmoglobin' would have to be distributed in the red cell interior. Nothing can be said as to how it is distributed, except that if it were distributed uniformly, its concentration would be about 7 per cent of the hæmoglobin concentration.

In the case of persons with a hæmoglobin concentration of about 25 gm. per cent, the average discrepancy between C_i and C_{Hb} is about 16 per cent, C_{Hb} being again put at 100 gm. per cent. Over the range $C_{\mathrm{Hb}} = 25$–35 gm. per cent, the refractive index increment α is substantially constant.

ANIMAL PHYSIOLOGY

Detection of Heterozygous Carriers in Glycogen Storage Disease of the Liver (von Gierke's Disease)

IN 1929, von Gierke[1] described a rare congenital disorder of carbohydrate metabolism characterized by excessive deposition of glycogen in various organs of the body. Cori and Cori[2] have shown that there is a deficiency of glucose-6-phosphatase activity in the liver in such patients. The occurrence of this condition in siblings[3] and among the offsprings of consanguineous matings[4], together with its equal distribution in both sexes, suggests that it is probably transmitted by a single autosomal recessive gene. In this situation, one would expect the disease to occur only in persons who receive two of the abnormal genes, one from each parent. If an individual is heterozygous for the condition, he will usually be free of clinical symptoms. Careful biochemical studies, however, might reveal minor departures from the norm[5].

Kapila, Kaul and Chattesjee[6] have reported on a family where the father, mother and siblings of a patient with von Gierke's disease showed a borderline response of blood glucose-levels to 0·25 ml. of adrenalin intramuscularly. One of the siblings also showed a flat oral glucose tolerance curve.

Recently, Wagner, Meyerriecks and Sparaco[7] have shown that there is an excessive accumulation of phosphorylated intermediates of the glycolytic cycle in the whole blood and plasma of patients with von Gierke's disease. Similar changes have now been noted among the parents of such patients and forms the basis of the present communication.

Glucose-6-phosphate and fructose-6-phosphate were determined in the following manner: 3–4 ml. of whole blood was collected in heparin and the serum was removed by centrifugation. The red cells were washed with normal saline, weighed and dissolved in 10 per cent trichloracetic acid. It was found that between 0·3 and 0·5 gm. of red cells dissolved in 8 ml. of trichloracetic acid gave the best results.

A 'Dowex-1' (10 × 100–200 mesh) column, which had previously been washed first with 20 per cent formic acid until free of chloride and afterwards with distilled water, was used for separation. All the trichloracetic acid extract was placed on the column and washed with 10 ml. of distilled water. The glucose-6-phosphate was eluted with 0·2 *M* ammonium formate solution *p*H 7·25. The fructose-6-phosphate was eluted with 0·5 *M* ammonium formate *p*H 7·25. The eluant was collected in separate 25-ml. volumetric flasks and collection was continued until three successive flasks were free of sugar. The colour

Table 1. RESULTS OF DETERMINATIONS DONE ON NORMAL CONTROLS, HETEROZYGOTES AND AFFECTED INDIVIDUALS EXPRESSED AS GM./100 GM. RED CELLS

Statistical analysis for hererozygotes versus controls of glucose-6 phosphate (G-6-P) showed $t = 5{\cdot}33$ and fructose-6-phosphate (F-6-P) showed $t = 9{\cdot}01$.

	Normals		Heterozygotes		Affected	
	G-6-P	F-6-P	G-6-P	F-6-P	G-6-P	F-6-P
No.	10	10	8	8	4	4
Mean	0·18	0·38	1·10	1·56	1·09	1·30
S.D.	±0·12	±0·14	±0·45	±0·32	±0·34	±0·20
Range	0·05–0·37	0·12–0·57	0·70–2·17	0·86–2·07	0·80–1·67	1·15–1·62

was developed with anthrone reagent and read at 620 mμ in the Beckman *DU* spectrophotometer.

The results were compared with those obtained from standard solutions of glucose-6-phosphate and fructose-6-phosphate and expressed as gm./100 gm. of red cells.

The results from 10 normal controls, 8 heterozygotes (parents of affected children) and 4 patients with von Gierke's disease are given in Table 1. It is apparent that the levels of glucose-6-phosphate and fructose-6-phosphate in the red cells of heterozygotes are significantly different from those of the normal controls and more closely resemble that of those with the disease.

These findings are in agreement with the data of Wagner, Meyerriecks, and Sparaco[7], who demonstrated the accumulation of phosphorylated intermediates of the glycolytic cycle in the peripheral blood of patients with von Gierke's disease. While the results in a single individual must be interpreted with caution, the abnormal values for glucose-6-phosphate and fructose-6-phosphate in a group of known heterozygotes suggest that this may be a phenotypic expression of a single recessive gene for von Gierke's disease. This would provide additional confirmation for the view that the lack of glucose-6-phosphatase is the primary lesion in the disease and extend the concept of being able to detect heterozygous carriers biochemically, as has been shown in the abnormal hæmoglobins[8], phenylketonuria[9] and galactosæmia[10].

We wish to express our appreciation to Drs. Howard Traisman and Ira Rosenthal for sending three of the cases and to Drs. Robert Dowben and Richard Wagner for advice regarding the laboratory methods.

An Enzymatic Basis for the Acceleration of Ciliary Activity by Negative Air Ions

IT has recently been shown that small negative air ions accelerate the tracheal ciliary activity of mammals both *in vitro* and *in vivo*[1,2]. The subsequent discovery that the actual mediator of these effects is negatively ionized oxygen[3] suggested the possibility of a direct action by negative air ions on one or more of the respiratory enzymes. This seemed increasingly likely when it was found that: (*a*) dilute solutions of sodium azide (as low as 1×10^{-5} molar) inhibit ciliary activity; (*b*) the hæmoglobin of animals killed with carbon dioxide recovers its bright red colour more rapidly in a negatively ionized atmosphere than in ordinary air.

Accordingly, a modified Keilin–Hartree pig heart homogenate[4,5] was prepared and the effect of (–) air ions on its catalytic activity was studied.

The rate of conversion of succinate to fumarate by the homogenate was followed by observing the increase in optical density of the mixture at 250 mμ[6]. Test solutions were exposed in a variety of ways with substantially the same results; in the most convenient method, 0·9 ml. 1 molar disodium succinate, 2·0 ml. boiled and cooled 0·2 molar phosphate buffer at *p*H 7·3, and 0·1 ml. heart homogenate (1 : 10 dilution) were combined in a Beckman silica glass cuvette. After the zero-time reading, the cuvettes were placed in specially designed chambers which permitted exposure to air ions while the solutions were being stirred with magnetic stirrers. Unipolar ion densities of 1×10^8/cm.^{2}/sec. at the fluid–air interface were delivered by 'Wesix' ionizers[7,8] consisting of tritium in a sealed foil with a reversible rectifying circuit to permit selection of either (+) or (–) air ions. At regular intervals the cuvettes were removed and their optical densities read in a Beckman *DU* spectrophotometer. Experiments were run at room temperature; periodic readings with an electronic

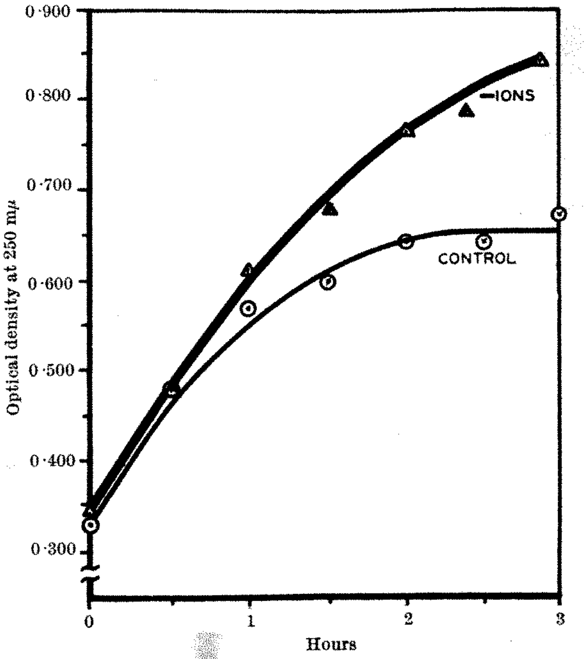

Fig. 1. The rate of conversion of succinate to fumarate by a Keilin–Hartree pig-heart homogenate in normal and negatively ionized atmospheres

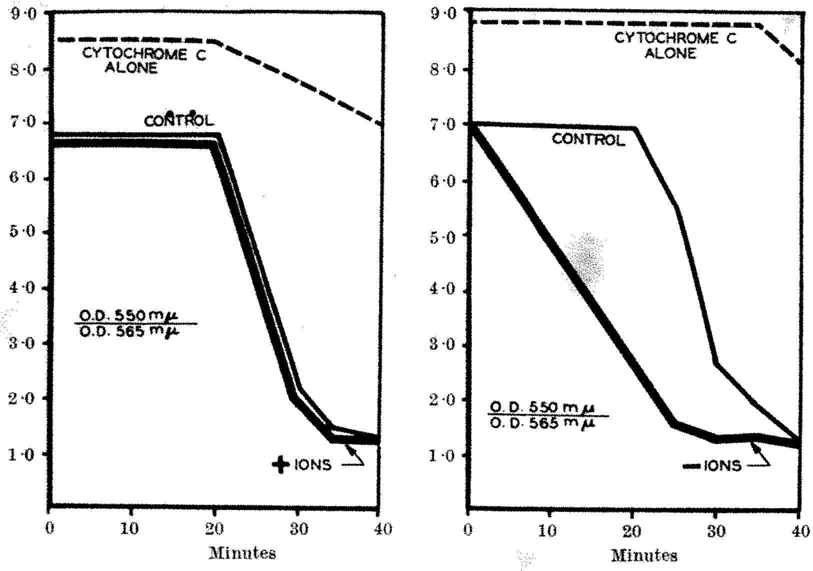

Fig. 2. The re-oxidation by cytochrome oxidase in normal and ionized atmospheres of cytochrome *c* reduced by sodium hydrosulphite. The dotted line shows the behaviour of cytochrome *c* in the absence of cytochrome oxidase in ionized and un-ionized atmospheres

thermometer established that there was no temperature variation between test and control samples.

As shown in Fig. 1, fumarate formation was more rapid in the negatively ionized sample. Positive ions were without effect.

In order to localize further the action of negative ions, experiments were performed on the rate of oxidation of cytochrome *c* alone and on cytochrome *c* plus heart homogenate. A 50-micromolar solution of commercial horse-heart cytochrome *c* ('Sigma') in 0·2 molar phosphate buffer at *p*H 7·3 was reduced with sodium hydrosulphite; 3 ml. samples were placed in control and ionizing chambers; re-oxidation was followed by regular spectrophotometric readings at 550 mμ and 565 mμ according to Paul's method[9]. Positive and negative air ions were without effect on the re-oxidation of cytochrome *c* alone. However, when 0·1 ml. of the cytochrome oxidase-containing Keilin–Hartree homogenate (1 : 10 dilution) was added to the solution, negative ions had a distinctly accelerating effect on the re-oxidation of cytochrome *c*; positive ions had no effect (Fig. 2).

Since sodium hydrosulphite may react with air to form hydrogen peroxide, experiments were performed in which the cytochrome *c* was reduced by either cysteine or ascorbic acid. The results were similar (Table 1). Preliminary exposure of the reductant alone (in solution) to (+) or (−) ions in no way altered the efficacy of the reductant.

It thus appears that negative air ions act directly on cytochrome oxidase, or else form a radical upon contact with water which acts directly on cytochrome oxidase. These experiments provide a reasonable explanation for the accelerating action of negative air ions on the tracheal ciliary rate. They fail to explain, however, the markedly inhibiting effects of positive air ions on the ciliary rate[1,2].

Table 1. RE-OXIDATION BY CYTOCHROME OXIDASE IN NORMAL AND NEGATIVELY IONIZED ATMOSPHERES OF CYTOCHROME *c* REDUCED BY OTHER METHODS

Time of exposure (min.)	Ratio $\frac{\text{Optical density at 550 m}\mu}{\text{Optical density at 565 m}\mu}$ (Cysteine-reduced) (C)	(−)	(Ascorbic acid-reduced) (C)	(−)
0	7·7	7·7	4·5	4·8
40	6·9	6·5	3·5	3·5
60	5·5	1·5	3·0	2·6
80	1·3	1·3	2·5	2·1

Taken in conjunction with the observed action of negative air ions on hæmoglobin, these experiments support the postulate that: it is the distinctive ability of negative air ions—or, more precisely, negatively ionized-oxygen—to react more rapidly with certain iron porphyrin compounds that is responsible for many of their physiological effects (that is, the decrease in respiratory-rate, the increase in the rate of tracheal ciliary beating, the increase in the rate of mucus flow).

We should like to thank Dr. J. B. Neilands for his helpful advice during the early phases of this work.

Changes in Serum Transaminase Activity following Myocardial Damage due to Lymphatic Congestion

LIGATION of the paracardial lymphatic glands and of the main paracardial lymphatic trunks results in myocardial damage and pathological changes of the electrocardiogram[1]. It is now well known that myocardial damage due to coronary occlusion is accompanied by increase of serum transaminase activity[2,3]. Starting from these facts we investigated the changes in serum transaminase activity following lymphatic obstruction.

The experiments were carried out in dogs of both sexes with average weights of 10–12 kgm. In 7 dogs under chloralose anæsthesia (0·1 gm./kgm. bodyweight) and sterile conditions a thoracotomy was performed on the right side; the paracardial lymphatic glands, the right lymphatic trunk and the

thoracic duct were ligated[4,5]. Sham-operations consisted of thoracotomy in three animals, and thoracotomy plus ligation of cervical glands and the thoracic duct in two animals. Transaminase activity was determined by Umbreit's method in blood drawn daily before and after intervention[6].

Results are given in Table 1. Maximal values up to 3 days before and after intervention are shown. It is evident that glutamic-oxaloacetic acid transaminase activity in sera after intervention increased significantly compared with the controls. Changes in serum glutamic-pyruvic acid transaminase activity were not significant.

Lymphatic obstruction as described above results in the majority of cases in a varying degree of histological change in the myocardium. This is proved by the increased activity of serum glutamic-oxaloacetic acid transaminase. This rise in glutamic-oxaloacetic acid transaminase activity after myocardial damage is analogous to the rise in glutamic-pyruvic acid transaminase activity after hepatic damage[7,8]. It remains unexplained that lymphatic congestion of the liver due to ligation of the thoracic duct does not bring about changes in serum glutamic-pyruvic acid transaminase activity.

We wish to thank Mr. P. Csáki of the Mathematical Institute of the Hungarian Academy of Sciences for the statistical analysis.

Effects of X- and Ultra-violet Irradiation on the Incorporation of Phosphorus-32 into Isolated Nuclei of Rabbit Appendix

IN previous studies[1] it was observed that the removal of deoxyribonucleic acid from rabbit appendix nuclei isolated in sucrose severely impairs the incorporation of phosphorus-32 into deoxyribonucleic acid, ribonucleic acid, and into organic acid-soluble phosphate. The lost capacity for incorporation can be restored by the addition of some polyanionic compounds, such as calf thymus deoxyribonucleate, yeast ribonucleate, or chondroitin sulphate. By treating the nuclei with pancreatic deoxyribonuclease in the presence of chondroitin sulphate, we have now succeeded in removing the bulk of deoxyribonucleic acid from the nucleus without appreciably affecting its capacity for incorporation (Table 1). An essentially similar but far more extensive observation has recently been reported by Allfrey and Mirsky[2] on the incorporation of labelled precursors into proteins and ribonucleic acids of calf thymus nuclei. However, the incorporation of phosphorus-32 into deoxyribonucleic acid was rather exceptional in this respect, because it could not be retained by chondroitin sulphate when the removal of deoxyribonucleic acid was too extensive (Table 1). This observation confirms the previous finding using sodium nucleates as the restoring agent[1].

Table 1. EFFECT OF TREATMENT WITH PANCREATIC DEOXYRIBONUCLEASE IN THE PRESENCE OF CHONDROITIN SULPHATE ON THE CAPACITY OF PHOSPHORUS-32 UPTAKE OF ISOLATED NUCLEI

Percentage of deoxyribonucleic acid removed	Total radioactivity (percentage of non-digested control)		
	Deoxyribonucleic acid	Ribonucleic acid	Organic acid-soluble phosphate
68	147	98	111
99	0	98	92

Cf. ref. 1 for the preparation of nuclei, method of incubation, and analytical procedure. The nuclei were first treated with 500 μgm./ml. of deoxyribonuclease (Worthington) in the presence of 5 mgm./ml. of chondroitin sulphate. Undigested controls were incubated in the same medium without the enzyme and chondroitin sulphate. They were then appropriately washed (ref. 1) and incubated with phosphorus-32.

We can thus have nuclei depleted of their deoxyribonucleic acid but still metabolically active. They are obviously interesting material for examining the role of deoxyribonucleic acid in the development of the irradiation lesion in the nucleus.

Isolated nuclei of rabbit appendix are much more resistant to X-irradiation *in vitro* than the lymphatic cells isolated from the same organ. Thus the X-irradiation (cf. ref. 3 for details) up to 580 r. did not affect the incorporation into deoxyribonucleic acid and organic acid-soluble phosphate; that into ribonucleic acid was not affected in some active preparations, but was inhibited by about 50 per cent in other preparations which showed relatively low incorporation into deoxyribonucleic acid (Table 2*B*). The lymphatic cells always showed a definite decrease in the uptake of phosphorus-32 into both types of nucleic acids by an X-ray dose of this order, administered *in vitro*[3].

Irradiation with ultra-violet (8–10 min. at 1 m. from a Toshiba 15-W. germicidal lamp; 16–20 times the dose killing more than 99·5 per cent of *Escherichia coli B*) reduced the incorporation into both ribo- and deoxyribo-nucleic acid by 50 per cent or more. At the lower doses (0·5–2 min.) the incorporation into ribonucleic acid was inhibited to a lesser extent while

Table 2. EFFECTS OF DEPLETION OF DEOXYRIBONUCLEIC ACID IN ISOLATED NUCLEI ON THE DEVELOPMENT OF IRRADIATION-INDUCED INHIBITION OF PHOSPHORUS-32 INCORPORATION INTO NUCLEIC ACIDS

Radiation		Concentration of deoxyribonuclease (μgm./ml.)	Percentage of deoxyribonucleic acid removed	Total radioactivity (percentage of unirradiated control)		
Type	Dose			Deoxyribonucleic acid	Ribonucleic acid	Organic acid-soluble phosphate

	8 min.	0	0	44	54	93
	10 min.	250	46	20	25	84
	10 min.	500	68	22	14	103
(*B*) X-rays	580 r.	0	0	87	41	91
		250	25	99	88	87
	540 r.	0	0	89	48	83
		500	99	—	110	67

(*A*) The nuclei were first depleted of deoxyribonucleic acid as in Table 1, irradiated, and then incubated with phosphorus-32. Because of the agglutination of nuclei, undigested controls could not be irradiated in these experiments, and are not represented here; instead, the cited values of undigested nuclei are taken from separate experiments. (*B*) The control and irradiated nuclei were incubated with or without nuclease, washed and then exposed to phosphorus-32 as in Table 1.

that into deoxyribonucleic acid was rather enhanced. Again there was no significant effect on the incorporation into organic acid-soluble phosphate (Table 2*A*). It is remarkable that in the present system the incorporation into ribonucleic acid tended to be much more sensitive to X- and ultra-violet irradiation than that into deoxyribonucleic acid, which was not inhibited at all on many occasions.

The removal of deoxyribonucleic acid (up to 68 per cent) completely failed to reduce the inhibitory effect of subsequent ultra-violet irradiation on the incorporation into the two nucleic acids (Table 2*A*). This suggests that the observed effect of ultra-violet irradiation was mediated at least in part by some entity (or entities) other than deoxyribonucleic acid. The removal of deoxyribonucleic acid (25–99 per cent) effaced the effect of X-irradiation which preceded the digestion of nuclei with deoxyribonuclease (Table 2*B*), suggesting that deoxyribonucleic acid was involved in the development of X-ray-induced inhibition of phosphorus-32 uptake into ribonucleic acid of isolated nuclei.

Unfortunately, the completion of this work had to be postponed, because the appendix nuclei become inactive during the cold seasons[1]. Details will be published later together with the results of some supplementary experiments yet to be performed.

This work was supported in part by the Scientific Research Funds of the Ministry of Education. Facilities given by Prof. K. Sakurai and his staff, Yamaguti Medical School, in the experiments of X-irradiation are acknowledged. Thanks are further due to Mr. K. Kimura for his help in some of the experiments.

Inhibition of Polynucleotide Phosphorylase by Degraded Ribonucleic Acid : its Reversal by Various Agents

STUDIES in this Laboratory have shown that non-dialysable commercial yeast ribonucleic acid and alkaline degraded polyadenylic acid strongly inhibit the polymerization of polyadenylic acid by polynucleotide phosphorylase from *M. lysodeikticus*[1]. Substantial inhibition also occurs with ribonucleic acid from *B. subtilis* partially digested with ribonuclease. The reaction of the inhibitor with the enzyme preparation is slow and may require up to 30 min. for completion. If the substrate, adenosine diphosphate, is added simultaneously with the ribonucleic acid the rate and extent of inhibition is reduced considerably. Concentrations of yeast ribonucleic acid as low as 10^{-7} *M* (phosphate) can give up to 100 per cent inhibition of synthesis of polyadenylic acid. However, in the presence of these inhibitors the rate of polymerization is autocatalytic and shows a significant lag, the extent of which depends upon the inhibitor concentration. Both the inhibition and the autocatalytic character of the rate-curve can be reduced or abolished by the addition of acridine orange, a *B. subtilis* ribonucleic acid preparation, or polyadenylic acid (Fig. 1).

Extensive digestion of ribonucleic acid from *B. subtilis* or yeast by ribonuclease results in a considerable or complete loss of inhibitory power. Dialysable fractions have been obtained which at concentrations of the order of 10^{-7} *M* reverse the inhibition by yeast ribonucleic acid completely. This material is adsorbed quantitatively by 'Amberlite *IRC*–400(*C*1)' resin and is eluted with 0·002 *N* hydrochloric acid. Control studies with orthophosphate, pyrophosphate and the 2′- and 3′-isomers of guanylic, adenylic, cytidylic and uridylic acids show

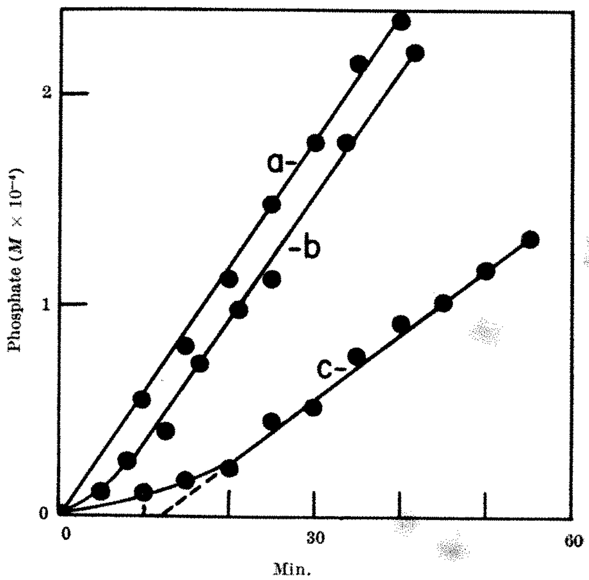

Fig. 1. Effect of yeast and *B. subtilis* ribonucleic acids on the polymerization of polynucleotide phosphorylase. Reaction mixture consisted of polynucleotide phosphorylase 113 from *M. lysodeikticus*, 0·017 *M tris*(hydroxymethylamino)methane buffer (*p*H 9·0), $1{\cdot}7 \times 10^{-4}$ *M* magnesium chloride, 0·2 *M* potassium chloride, 7×10^{-4} *M* adenosine diphosphate. Mixture was incubated at 37° for 30 min. with inhibitors and/or activators before the addition of adenosine diphosphate. Curve *a*, control; curve *b*, $1{\cdot}8 \times 10^{-7}$ *M* yeast ribonucleic acid, $1{\cdot}8 \times 10^{-4}$ *M B. subtilis* ribonucleic acid; curve *c*, $1{\cdot}8 \times 10^{-7}$ *M* yeast ribonucleic acid. Rate recorded as moles of inorganic phosphate liberated per litre of reaction mixture

no activation effect. The possibility that 2′,3′-cyclic phosphate nucleotides (cyclic-cytidylic and cyclic-uridylic acids) are involved is being investigated. Paper chromatographic studies indicate that the activity is associated with material which behaves like these compounds. Non-dialysable fractions have also been obtained which reverse inhibition by ribonucleic acid; these are probably low molecular weight or 'core' material.

The inhibition is both competitive and non-competitive with respect to adenosine diphosphate, showing a decrease in $V_{\text{max.}}$ and an increase in K_m. The inhibition is maximum at low magnesium concentrations ($< 2 \times 10^{-4}\ M$) and decreases to a constant per cent at optimum and inhibitory concentrations of magnesium ($> 4 \times 10^{-4}\ M$). Inhibition of ribonucleic acid increases from a negligible amount with no salt to a maximum at high salt concentration[1]. The extent of inhibition by contaminating ribonucleic acid depends upon the total acid and the ratio of inhibitory and non-inhibitory acid. Preparations of polynucleotide phosphorylase from *B. subtilis* containing high concentrations of ribonucleic acid (280/260 mμ ratio 0·5) lose activity upon standing; this activity can be recovered almost quantitatively by fractionation with ammonium sulphate or by the addition of acridine orange. Treatment of *B. subtilis* polynucleotide phosphorylase preparations with ribonuclease results in a total loss of enzyme activity, whereas similar treatment of *M. lysodeikticus* preparations shows a negligible effect. *B. subtilis* polynucleotide phosphorylase preparations partially inhibited by contaminating ribonucleic acid fail to show any salt activation, whereas freshly prepared and refractionated material is activated by potassium chloride to the same degree as are preparations from *M. lysodeikticus*[2]. Similar salt activation has been observed with preparations from *B. megaterium*.

All enzyme preparations show some activation by acridine orange. The concentration of dye required for and the extent of activation are an order of magnitude greater with preparations of polynucleotide phosphorylase from *B. subtilis* ($2{\cdot}3 \times 10^{-4}\ M$, 75 per cent, 280/260 mμ ratio 0·5) than with those from *M. lysodeikticus* ($10^{-5}\ M$, 7 per cent, 280/260 mμ ratio 1·4–1·7). The quantity of dye required for maximum activation increases with the concentration of ribonucleic acid in the preparation and also, perhaps, with the ratio of inhibitory to non-inhibitory ribonucleic acid. Excess dye inhibits the reaction[3,4].

The extent of inhibition also depends upon the substrate. In an experiment with $10^{-6}\ M$ yeast ribonucleic acid and *M. lysodeikticus* polynucleotide phosphorylase polymerization of polyadenylic acid was inhibited more than 95 per cent, whereas that of polyuridylic acid was only slightly affected.

The kinetics shown in Fig. 1 resemble those described by Mii and Ochoa[5] with preparations of *A. vinlandii* containing an estimated 3 per cent ribonucleic acid. The autocatalytic rate curve and 'priming' action of polynucleotides cannot be demonstrated with *M. lysodeikticus* preparations unless degraded ribonucleic acid or polyadenylic acid is added. It is of interest to note, also, that salt activation observed with *M. lysodeikticus* polynucleotide phosphorylase has not been reported for *A. vinlandii* preparations, whereas the addition of degraded ribonucleic acid to *M. lysodeikticus* preparations abolishes the salt activation process. Finally, the progressive inhibition on standing of polynucleotide phosphorylase from *B. subtilis*, which can be accelerated by the addition of ribonuclease, produces an enzyme-inhibitor system which resembles the *M. lysodeikticus*–yeast–ribonucleic acid mixture and the *A. vinlandii* preparations. We suggest that the results obtained with polynucleotide phosphorylase from *A. vinlandii* by Mii and Ochoa[5] and polynucleotide phosphorylase from *M. lysodeikticus* and *B. subtilis* can be explained by a common mechanism, namely, the inhibition of the polymerization process by degraded ribonucleic acid added or present in the enzyme preparations as contaminant and the reversal of this inhibition by the addition of non-inhibitory or 'active' polynucleotides or 'primers'. A similar explanation can account for the specificity toward different substrates by various preparations of polynucleotide phosphorylase from *M. lysodeikticus* reported by Olmsted[6]. It appears probable that the specificity of priming[5] by different polynucleotides[7] is related to the specificity of inhibition.

The mechanism of inhibition probably involves the 3′-phosphate-ended groups of the polynucleotides[1]. Judging from the initial studies with degraded ribonucleic acid, a minimum molecular weight is necessary for the inhibition. The reversal of inhibition by acridine orange is presumably the result of the specific reaction of the 3′-phosphate-ended groups with the dye to form complex II[3,8]. Reversal of inhibition by highly polymerized *B. subtilis* ribonucleic acid or polyadenylic acid suggests a competitive displacement of the 3′-phosphate-ended polymers from the active enzyme site. The partial reversal of inhibition with increasing substrate concentrations is in conformity with the earlier finding[8] that increased adenosine diphosphate concentrations increase the concentration of molecules of polyadenylic acid. The fact that there is a non-linear relationship between substrate and polymer concentrations may explain the non-competitive character of the inhibition. The autocatalytic nature of the inhibited catalysis of synthesis of polyadenylic acid reflects the increase in concentration of polymer molecules during the reaction[8], that is, the *de novo* synthesis of polymer.

The mechanism of action of the dialysable and non-dialysable fragments of ribonucleic acid is more obscure but may be related to the findings reported by Heppel[9] that 3′-phosphate-ended oligonucleotides activate *A. vinlandii* polynucleotide phosphorylase. The fact that they are not incorporated into the products suggests that they may be acting as templates. However, it appears highly probable that the activation by the dialysable material may be via the formation of oligonucleotides from the cyclic-nucleotides as described by Heppel, Whitfeld and Markham[10].

Irrespective of the underlying mechanisms associated with these results, the significant conclusion to be reached is that polynucleotides, through their activation and inhibitory effects, can alter the specificity of the polynucleotide phosphorylase enzyme toward different substrates. This is believed to be brought about not by the addition of monomers to preformed 'primer'[5,8] but by the alteration of the *de novo* synthesis of polynucleotides. It is interesting to speculate whether such a mechanism is at work in the cell in the duplication of ribonucleic acid.

This research has been supported by the Louise C. Bowles Research Fund, by U.S. Public Health Grant No. *C*–3293(*C*1), National Cancer Institute, and by a grant from Miles Laboratories, Inc. I am grateful for the technical assistance of Misses G. Armelie, R. Shriver and Mrs. N. Morton, as well as for the helpful discussion of this paper with Dr. D. D. Hendley.

Neuronal Dye-Sorption as a Histochemical Indicator of Nervous Activity

PROTEIN extracts from electrically stimulated nervous tissue have been reported to undergo changes resembling those of reversible denaturation[1]. Denaturation of protein, however, enhances dye-protein interaction[2]. It was postulated, therefore, that excitation of nervous tissue could be demonstrated histochemically[3].

Since protein in the denatured state has more ionized tyrosine hydroxyl and cysteine sulphydryl groups available than in the native state, iodination, by lowering the *pK* of the protein, will further increase its affinity for basic dyes[4]. Based on these considerations, the following technique has been developed.

Preservation of the living central nervous system tissue was achieved by immediate submersion into liquid nitrogen. Sections 3μ in thickness were cut in the cryostat at −10° C. and mounted on slides by warming with the fingertip. The sections were then treated in 0·5 per cent w/v of iodine in 95 per cent ethanol for 1 min. at room temperature. Descending concentrations of alcohol and finally distilled water were used to remove non-reacted iodine. The sections were then stained in a *tris*-buffered aqueous 1 per cent methylene blue hydrochloride (*C.I.* No. 922 ; Nat. Aniline dye) solution of *p*H 6·9[5]. Treatment with two changes of aqueous 15 per cent sodium chloride solution prior to rinsing in distilled water and mounting in lævulose or preferably in Lillie's cellulose caprate retarded leaching of the dye. Each step has been standardized.

This staining procedure has been applied to the brain tissue of male Sprague–Dawley rats 90–100 days old. Excitation was produced by either electroconvulsive shocks or by intraperitoneal administration of 0·45 mgm. of picrotoxin/100 gm. body-weight. Animals anæsthetized by 6 mgm./100 gm. body-weight of intraperitoneal nembutal served as controls. At the peak of excitation or depression the animals were instantaneously decapitated in such a way that the head dropped into liquid nitrogen. One minute later the heads were cut in frontal sections by a band saw and the brain tissue removed and blocked for sectioning. During this procedure the tissue remained frozen.

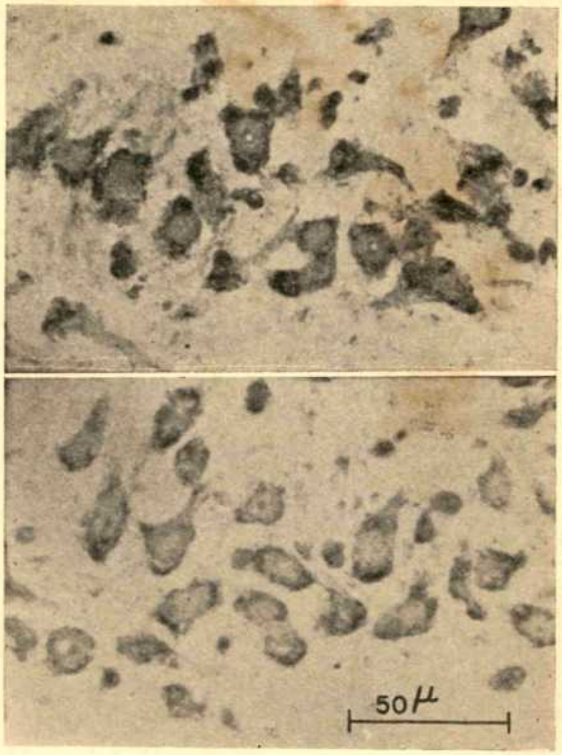

Fig. 1. Rat brain. Large pyramidal cells of hippocampus stained with methylene blue. Above : after excitation with picrotoxin ; below : after depression with nembutal

Excited and control brains were sectioned immediately and mounted on the same slide for comparison. Care was taken to obtain microscopic preparations of corresponding topographical areas.

Surfaces of neurons of excited central nervous system tissue were consistently stained more intensely than surfaces of non-excited, depressed nerve cells. This difference in intensity can only be observed under the microscope (Fig. 1). In addition to the surface of the excited ganglion cell body, the dendrites were also found to be stained to a degree not matched by the control preparations. The nuclei of the nerve cells were not demonstrable. Although glial nuclei are distinctly stained, no consistent differences in staining intensity could be observed between excited and depressed tissue.

Similar findings were revealed in brain sections of twenty-two day old *DBA*–2 mice. In this case excitation was produced by seizures following sonic vibrations of 90 decibels of 1-min. duration. Those litter mates which did not show convulsions under identical conditions served as controls.

Preliminary studies indicate that another phenothiazine derivative, chlorpromazine hydrochloride, follows the same pattern of differential sorption as does methylene blue. When chlorpromazine is used as a 'colourless dye' the differences in sorption must be viewed under a fluorescence microscope.

The nature of the morphological and/or chemical structures involved in the differential sorption of certain phenothiazines has yet to be determined. Pertinent investigations are under way. It is also planned to measure the uptake of dye quantitatively. In connexion with the results reported here it is intriguing to recall that Bodoni[6] observed the tranquillizing action of methylene blue on agitated mental patients as early as 1899.

This work was carried out with the technical assistance of Thomas P. Biggert. The active interest and helpful suggestions of Dr. B. Pasamanick are gratefully acknowledged. Dr. S. Levine kindly placed the *DBA*–2 mice at our disposal. Smith, French and Kline courteously supplied the chlorpromazine hydrochloride.

PLANT PHYSIOLOGY

Gibberellic Acid and Growth Correlations

AMONG other effects, gibberellic acid may alter plant-growth correlations by decreasing the inhibitory action of leaves and storage organs. Previous work[1–3] has shown that species of *Bryophyllum*, *B. crenatum*, *B. verticillatum* and *B. daigremontanum* do not flower if kept continually under either long- or short-day conditions. To induce flowering, long-day plants showing long internodes and petiolated oval leaves must be exposed daily for 10 days to 12-hr. illumination or less, whereas short-day plants with their very short internodes and round, almost sessile, leaves must be exposed for 20 days to a long day of 13 hr. or more and then to short-day conditions for a further 10 days. These plants were therefore described as long-short-day plants[4]. The long-day plants could not be induced to flower by treatment with gibberellic acid. Bünsow and Harder were able to induce elongation and flowering of long-day plants grown under short-day conditions by treatment with gibberellins obtained from the fungus[5] and from unripe bean seeds[6]. The same result was obtained in our laboratory by treatment with gibberellic acid of material of *Bryophyllum crenatum* which had been maintained in the form of rosettes for 12 years by continuous exposure only to short-day conditions. If, however, after treatment with gibberellic acid these short-day plants were exposed to continuous illumination or to long-day conditions, they failed to form flower primordia although they elongated strongly, forming long internodes and new oval petiolated leaves. Thus gibberellic acid can replace the long-day requirement but not the quite specific flower-inducing effect of the short day. Extremely rarely a single flower appeared in the axil of one of the upper leaves of the rosette plants grown under short-day conditions; this was only observed in the spring of 1949 in two out of many hundred plants grown in a 9-hr. day.

Studies have also been made with the long-day plant *Circaea intermedia*, which was the first in which the inhibiting effect of higher concentrations of indole-3-acetic acid on flowering was demonstrated[7]. Weak plants which had remained apparently vegetative even under long-day conditions elongated considerably and flowered when a paste containing 0·5 per cent of gibberellic acid was applied to the stem apex. The same effect is produced by defoliation of the upper part of the stem and so removing the leaves controlling growth inhibitions. Tubers of this plant gathered in autumn and then treated at the apex with gibberellic acid paste formed many long orthotropic filamentous shoots whereas control tubers smeared with pure lanolin either remained dormant or developed slowly growing horizontal stolons with tubers at the end. A similar change in geotropic response also occurred with axillary shoots. When axillary buds in one-node cuttings taken from the basal part of the stem were treated with gibberellic acid paste they developed into long and very thin vertical shoots, whereas the control buds smeared with pure lanolin grew into plagiotropic stolons which tuberized. Thus the correlative growth inhibitions of leaves and tubers, so important for the correlations of growth processes, may be decreased by application of gibberellic acid, which thus replaces the growth-promoting effect of the roots.

Chlorophyll a in some Corals and Marine Plants

ASSOCIATIONS of algae and marine invertebrates are common in coral reefs of tropical seas. According to Yonge[1,2] the algal components of corals obtain carbon dioxide and nutrients from the associated animals; but just what advantages of pseudo-symbiosis accrue for the individual animal body has not been clearly demonstrated. Odum and Odum[3] have expressed the view that the algal-coelenterate complex of tropical coral reefs is "a highly integrated ecological unit (comparable to the algal-fungal complex of a lichen) which permits cyclic use and re-use of food and nutrients necessary for vigorous coral growth in tropical 'desert' waters having a very low plankton content". New approaches to this problem of symbiosis have been developed recently by the growing of single-celled zooxanthellæ isolated in pure cultures from marine jelly fish and sea anemones, and demonstration that these are in reality motile dinoflagellates[4]. It has not been clearly shown whether these photosynthetic flagellates contribute food supplies to the animal polyps.

If the trophic structure of a coral reef is a pyramid of biomass with a considerable excess of producing organisms at the base, then it becomes important to know more about the synthetic potential of the different kinds of primary producers in the reef. Quantitative analysis of pigments can give a measure of the assimilatory potential of green organisms which absorb radiant energy used in photosynthesis. Although various methods, such as the oxygen method and carbon-14 technique, may give precise indications of actual productivity, it is believed that determinations of the chlorophyll *a* content of plankton, algae, corals, etc., may have considerable significance in various problems concerned with productivity and food relations among groups of organisms in the sea.

The present study attempts to assess the chlorophyll potential of a number of different kinds of corals and sea anemones, and to compare them with other photosynthetic systems of algae and flowering plants in a tropical marine environment. Samples of plants and animals were collected near the Marine Laboratory at La Parguera, Puerto Rico, during March 1958. The pigmented portions of these organisms were ground and extracted with 90 per cent acetone in a mortar. After filtration in subdued light, the extracts were made to standard volume, and their absorption was determined at appropriate wave-lengths in a Beckman spectrophotometer. Calculations of chlorophyll *a* per gram of fresh samples were made according to the method of Richards with Thompson[5].

The general results of this survey can be illustrated by results obtained for representative types of organisms, a few of which are shown in Table 1. A summary of the results, arranged according to ten different groups of chlorophyll concentration, is presented in Table 2. Although the distribution of chlorophyll *a* in plants and animals shows overlap in the lowest four groups of Table 2, it is obvious that the concentration of pigment is relatively low in most of the animals studied. Among the various corals and anemones, high chlorophyll values were found in gorgonian corals and in *Condylactis*. Seven species of plants showed chlorophyll *a* contents greater than the maximum observed in any of the animals.

Table 1. CHLOROPHYLL *a* CONTENT (µGM./GM. WET WEIGHT) AND PIGMENT DENSITY RATIOS IN REPRESENTATIVE MARINE ORGANISMS OF PUERTO RICO

Organisms	Chlorophyll *a*	D_{480}/D_{665}
Corals		
Briareum asbestinum	97	6·1

Table 2. DISTRIBUTION OF CHLOROPHYLL *a* AMONG 23 MARINE PLANTS AND 30 ANIMALS GROWING IN SHALLOW WATERS NEAR LA PARGUERA, PUERTO RICO

	µgm. of chlorophyll *a* per gm. of tissue									
	1–100	101–200	201–300	301–400	401–500	501–600	601–700	701–800	801–900	901–1,000
Plants*	5	4	5	2	3	0	2	0	1	1
Animals	23	5	1	1	0	0	0	0	0	0

*Leaves of *Thalassia* occur in the 601–700 class, but chlorophyll *a* of the whole plant body falls into the low 1–100 class, along with the majority of corals.

Considerable variation occurred in the different samples of the species which were tested. Thus, five determinations for *Thalassia* gave results ranging from 462 to 655 µgm./gm. of fresh leaf tissue. When the value of 655 for *Thalassia* leaves is recalculated for the whole plant, then the result comes to only 73 µgm./gm. of plant body. If the calculation of pigment on the basis of the whole functional body of plants and animals gives a fair comparison, then many corals would be found to contain chlorophyll *a* in concentrations as high as those of common marine algae and flowering plants. The presence of significant amounts of chlorophyll *a*, along with other pigments in the fauna of coral reefs, is related chiefly to the presence of numerous unicellular algae, which live in association with the polyps. In some of the stony corals, green and blue green algae occur also in the hard structure. Studies on the overall productivity of these algae in the reef community, and symbiotic exchanges between zooxanthellæ and polyps are being continued.

The ratio of yellow to green pigments may have some significance in estimating the photosynthetic potential of carbon dioxide – light assimilatory systems. According to the data discussed by Richards with Thompson[5], carotenoid absorption may be best observed at wave-length 480 mμ, while chlorophyll *a* shows an absorption maximum near wave-length 665. Hence, we have chosen a simple expression of pigment density ratio = D_{480}/D_{665}, which roughly relates the optical density of the yellow pigments to that of the green pigments. Pigment density ratios for 16 corals, 5 anemones, 18 algae, and 4 phanerogamic plants have been calculated. Typical results are shown in Table 1. The range and average of pigment density ratios among the various groups are as follows: coral range 4·2–6·1, average 4·9; anemone range 4·2–5·3, average 4·6; algae range 1·5–2·7, average 1·8; phanerogam range 1·6–1·8, average 1·7. The leaves of flowering plants and the thalli of green algae commonly show a ratio of about 1·7, whereas the ratio found in corals and anemones is generally greater than 4·6. Studies on the pigment density ratio of the internal green algal bands and the outer brown polyp regions of two corals, *Porites furcata* and *Diploria clivosa*, gave ratios of about 1·6 for the green internal bands and approximately double this value for the polyp region. It appears that photosynthetic capacity is greatest in organisms having a low pigment density ratio, that is, a high proportion of chlorophylls to carotenoids. Carotenoids seem to be unusually abundant in the symbiotic corals and certain kinds of sea anemones.

BIOLOGY

Reactivation of Heat-inactivated Poxviruses: a General Phenomenon which includes the Fibroma–Myxoma Virus Transformation of Berry and Dedrick

IN 1936, Berry and Dedrick[1] reported that active myxoma virus could be recovered from rabbits injected with mixtures of heat-inactivated myxoma and active fibroma virus. Because their experiments were suggested by Griffith's[2] studies on the transformation of pneumococcal types, Berry and later investigators called heated myxoma virus the "transforming agent" and the phenomenon "fibroma-myxoma virus transformation". However, Berry recognized that reactivation of the heat-inactivated myxoma rather than transformation of the active fibroma virus was a possible alternative mechanism.

The term 'transformation', as used in bacterial genetics, has been defined as the heritable modification of the properties of one bacterial strain by an extract derived from cells of another strain. The active material responsible for transformation is deoxyribonucleic acid. There is no evidence that the phenomenon described by Berry and Dedrick is an example of transformation, in this sense. The process is better interpreted as reactivation of the inactivated virus, and we shall use that term henceforth.

Berry's results have been repeatedly confirmed, but further analysis of the mechanism was precluded by the irregular results obtained in intact animals. Recently, Kilham[4] showed that the Berry–Dedrick phenomenon could be demonstrated with regularity with heat-inactivated myxoma virus and active fibroma virus, in cultures of rabbit, monkey and squirrel kidney cells. With collaborators[5] he has described the effects on the heated myxoma virus component of some physical and enzymic treatments.

The definition of several independent genetic markers of vaccinia virus suggested that it might be a more suitable agent for the study of the mechanism of the Berry–Dedrick phenomenon than myxoma and fibroma viruses. The strains of vaccinia virus used for most experiments discussed here were those employed previously for recombination experiments[6]. Their biological characters are set out in Table 1.

Table 1. BIOLOGICAL CHARACTERS OF TWO STRAINS OF VACCINIA VIRUS (FROM REF. 6).

Designation of strain	Morphology of pock on chorioallantoic membrane	Production of hæmagglutinin	Heat resistance	Mouse virulence	Rabbit virulence
RP	hæmorrhagic ulcerated (U^+)	nil (A)	high (T^+)	high (VM^+)	high (VR^+)
V-Led-7N	white non-ulcerated (U)	high (A^+)	low (T)	low (VM)	low (VR)

The appropriate symbols for phenotypes are shown in brackets.

The virulent strain, *RP*, was used as the inactivated agent. After heating for 2½ hr. at 55° C. in 0·1 *M* sodium chloride, 0·01 *M* citrate, at *p*H 7, suspensions which originally contained about 10^8 pock-forming units/ml. were shown to be non-infective when inoculated on the chorioallantoic membrane, with passage of the membrane two days later. All heated material used was inactive by this test, which was the most sensitive available. Mixtures of heated *RP* and active *V-Led-7N* were inoculated intracerebrally in mice, and brains were removed for assay on the chorioallantoic membrane at various intervals. Such brain suspensions yielded clones of virus indistinguishable from *RP* in all the characters listed in Table 1, as well as recombinants between *RP* and *V-Led-7N*. Both the recombinants and *RP* were recovered as early as 18 hr. after inoculation. Since *V-Led-7N* multiplies to a limited extent only in the mouse brain, it was found only in the early stages. This result is directly comparable to Berry's observations, for living virulent virus was recovered from an animal inoculated with a mixture of heat-inactivated virulent virus and a related active attenuated strain. It also showed something that could not be determined with myxoma-fibroma, namely, that some clones of virulent virus resembled the original heat-inactivated virus in all the characters that could be examined, and that others, although highly virulent, were recombinants.

The mouse brain was used to test the capacity of heated *RP* to be reactivated after further physical, chemical and enzymic treatments. Suspensions of *RP* could be heated at 55° C. for more than 7 hr. before the capacity for reactivation was greatly reduced, but this was destroyed in a few minutes at 60° C. In contrast to the report of Smith[7] (for which detailed support has never been published) attempts to dissociate protein and deoxyribonucleic acid have so far been unsuccessful. As Kilham and his collaborators[5] found with myxoma virus, various forms of enzymic digestion of the heat-killed virus (trypsin and deoxyribonuclease at *p*H 11, pepsin at *p*H 3·5, papain at *p*H 7·5 and above) leave the capacity for reactivation intact and associated with particles deposited in the same centrifugal field as vaccinia virus.

Reactivation of heated *RP* was also observed after the inoculation of mixtures of heated *RP* and active *V-Led-7N* into cultures of HeLa cells, and on the chorioallantoic membrane. Use of the chorioallantoic membrane had the advantage that it allowed the direct demonstration of reactivation without the necessity of passage. When about 10^8 particles (originally 10^7 pock-forming units) of heated *RP* were inoculated on the chorioallantoic membrane together with 20–30 pock-forming units of active *V-Led-7N*, about half the pocks seen two days later were of the U^+ type, that is, they resembled those of *RP*. Analysis of 32 clones from U^+ and U pocks showed that nine resembled *V-Led-7N*, 11 resembled *RP* and 12 were recombinants. Using the chorioallantoic membrane, reactivation of heated *RP* has been induced not only by another strain of vaccinia (*V-Led-7N*) as the active agent but also by all the other members of the poxvirus group that have been tested, namely, cowpox, ectromelia, myxoma, fibroma and fowlpox. The reverse process, reactivation of heated *V-Led-7N* by active *RP* and by ectromelia virus, has also been accomplished. The phenomenon is probably a general one, demonstrable with many different combinations of pox viruses, although the ease of recognition of the reactivated component differs. Experiments with several other viruses which produce pocks on the chorioallantoic membrane yielded negative results; no reactivation of heated *RP* was observed when the active virus component was herpes simplex virus, influenza virus strain *WSE*, or Murray Valley encephalitis virus.

The search for recombinants between *RP* and reactivating viruses other than *V-Led-7N* is not yet completed, but reactivation of heated *RP* invariably yielded virus indistinguishable from *RP* in all the characters set out in Table 1 (U^{+} A T^{+} V ($M^{+}R^{+}$)). The recovery of such clones from mixtures of viruses as dissimilar as *RP* and fibroma or fowlpox renders unlikely Berry's original idea that the heat-inactivated component 'transforms' the active virus. Reactivation of the heated virus by the active agent is a more plausible explanation. Whether reactivation is accomplished by some sort of genetic interaction, or whether the primary mechanism is repair of some non-genetic damage of the heated virus, with recombination as a possible secondary event, cannot yet be decided.

Relation of Extracellular to Intracellular Potential Records from Single Cardiac Muscle Fibres

IN the atrial muscle of the heart the rate of depolarization (70–100 V./sec. at 30° C.) is so much more rapid than that of repolarization (less than 1·0 V./sec.) that the two events cannot be confused, and a comparison may be made between records obtained from the inside and outside of a single fibre during the depolarization phase only[1]. Pairs of isolated rabbit atria were mounted horizontally in oxygenated fluid and made to beat at constant frequency in response to electrical stimuli applied to the tip of the left atrium. Contractions were measured with a transducer, and action potentials from the left and right atria were recorded with pairs of small bipolar external electrodes, from which conduction velocity was calculated. Glass microelectrodes, filled with potassium chloride, with tips less than 0·5μ across and resistances of 10–30 MΩ, were introduced under visual control into single fibres on the endocardial surface by a manipulator which could be moved smoothly over distances as small as 2μ.

Fig. 1*A* shows a record of a cardiac action potential obtained with a microelectrode just touching the surface of a fibre. There were four phases : (1) upward positive, (2) fast downward negative, (3) upward positive to just above the base-line, (4) slow return to zero. The electrode was then lowered, and suddenly recorded a resting potential of −74 mV., indicating that it had penetrated a fibre. Fig. 1*B* shows the contraction of the atria (lowest trace), and the intracellular action potential above it. The dotted line represents the zero potential of the electrode when it was extracellular. The vertical trace on the right gives the records from the external bipolar electrodes, and the inset indicates the time to within 0·1 sec.

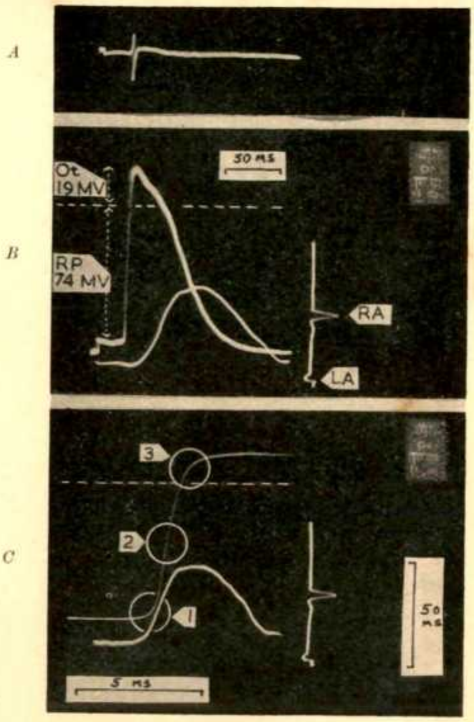

Fig. 1. *A*, Cardiac action potential recorded with microelectrode outside fibre. *B*, Lower trace, contraction ; upper trace, intracellular potential ; *RP*, resting potential ; *Ot*, overshoot ; dotted line, zero potential ; right-hand trace, external records of action potential from left (*LA*) and right atrium (*RA*) ; inset, time of exposure at 11 min., 7·1 sec. *C*, As *B*, except that the sweep recording the intracellular potential was faster. (Photographs not retouched)

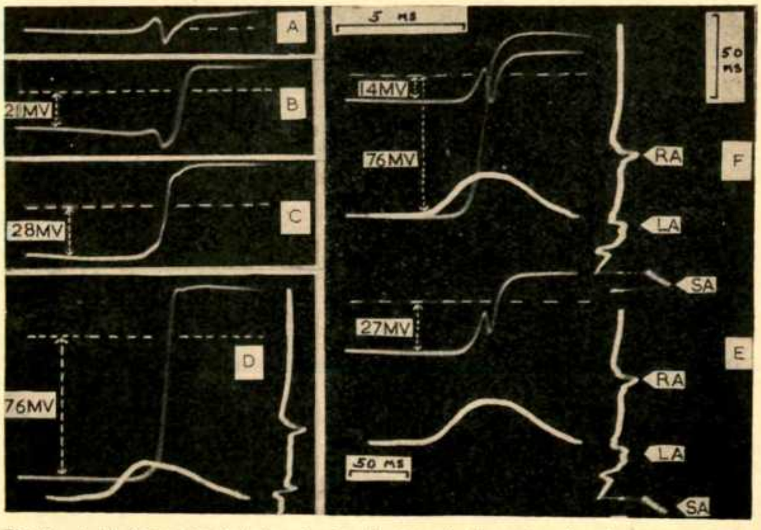

Fig. 2. *A–D*, Four records taken during the introduction of a microelectrode ; *E* and *F*, three records taken during consecutive heart beats to show that the negative phase of the action potential recorded when the electrode was extracellular corresponded to phase (2) of the action potential recorded intracellularly ; *S.A.*, stimulus artefact. (Photographs not retouched)

Comparison of Figs. 1*A* and 1*B* shows that phases (1) to (3) of the extracellular potential were associated with depolarization, and the slow phase (4) with repolarization. In Fig. 1*C* the oscilloscope trace of the intracellular potential had been speeded up

23 times, so that it showed the depolarization only, making the first three phases more distinct. The four phases might be interpreted as follows. (1) Membrane active at a distance and active region approaching the electrode. Both extracellular and intracellular records became positive in phase because the indifferent electrode was in contact with the active (outside negative) region via the extracellular fluid. (2) Active region at electrode. The electrode, when extracellular, was on the negative pole of the 'sodium battery'[2], and on the positive pole when intracellular, so that the two records were out of phase. (3) The intracellular record rose to peak positivity as the inflowing depolarizing current came to an end, and the extracellularly recorded potential also became positive as the active region travelled away from the microelectrode. (4) Resting potential restored as membrane very slowly repolarized. It has been remarked that surface records in a volume of fluid bear some resemblance to the second derivative of the monophasic potential[3], but this does not account for phase 4.

As a rule, when the microelectrode was introduced into a fibre, the full resting potential appeared with great suddenness. Occasionally, the resting potential developed slowly or irregularly, and such records were rejected. Some of these records, however, although valueless as measurements of resting potential, were of interest in showing that a record of resting potential was not a reliable criterion for judging whether an action potential was being recorded from inside or outside a cell. Figs. 2*A*–*D* shows four successive records taken during the penetration of a cardiac fibre. The record of Fig. 2*A* was obtained from an electrode just touching the surface of a fibre, and is comparable with Fig. 1*A*, except that the speed of the sweep recording the intracellular potential was faster. In Fig. 2*B*, a resting potential of 21 mV. had developed, yet the action potential could not be said to be of an intracellular type because phase (2) was negative. In Fig. 2*C*, on the other hand, although the resting potential had increased to only 28 mV., the action potential was of an intracellular type since phase (2) was now positive. In Fig. 2*D* the electrode was fully intracellular, and recorded a stable resting potential of 76 mV., and an action potential comparable with that of Fig. 1*C*.

The relation of the phases of the action potential recorded intracellularly and extracellularly is illustrated by Figs. 2*E* and *F*, in which three consecutive heart beats have been photographed, two of them on the same frame. In Fig. 2*E*, during the first beat, although a resting potential of 27 mV. was observed, the action potential was not of an intracellular type since phase (2) of the action potential was negative. Before the next beat the electrode entered the fibre, and the fast positive phase (2) of the upstroke of the action potential corresponds with the negative phase of the superimposed third record, when the electrode had again come out of the fibre. There was no change in conduction velocity between the beats, because the two superimposed records in Fig. 2*F* of externally recorded action potentials from the left and right atria (to the right of the frame) do not differ measurably from the single similar record in the preceding frame (Fig. 2*E*).

Microelectrodes inside single fibres of frog skeletal muscle do not record to a significant extent potentials occurring in surrounding fibres[4,5], and a tracing such as that of Fig. 1*C* provides no evidence that this is not also true of cardiac fibres. The simplest explanation for the records of Fig. 2, therefore, is that the electrode was at first in a fibre damaged to the extent that the resting potential was abnormally low and the action potential absent (Fig. 2*E*) or attenuated (Fig. 2*C*), but that the electrode was also recording as an external electrode the action potential in a subjacent fibre which it eventually entered (Figs. 2*D* and *F*). In any event it is apparent that the observation of a d.c. potential is inadequate evidence that an action potential superimposed on it is being recorded intracellularly, an assumption which can be made only if (*a*) there is a large and stable resting potential, (*b*) there is no negative component in phase (2) of the action potential.

Development in a Mutelid Lamellibranch

Although the life-history of lamellibranchs of the family Unionidae has been known for almost a century, little has been recorded concerning members of the related Mutelidae. This taxonomically ill-defined family has representatives in the fresh-waters of Africa, South America and Australia. A glochidial stage similar to that of the Unionidae is said to occur in the development of some reputed mutelids in Australia. At least one South American species produces a peculiar larva to which the name lasidium has been given but its subsequent development is unknown. Nothing has been recorded regarding the development of the African species.

Recent studies have elucidated the life-history of the African species *Mutela bourguignati* (Ancey) Bourguignat 1885, which is depicted in Fig. 1. The stages illustrated are referred to in the text by the relevant letters. The adult female produces numerous minute larvæ (*a*) which, while still within the egg membrane, are brooded in the inner demibranchs of the ctenidia. These larvæ are in some ways similar to the typical molluscan veliger but differ in certain respects, most of the differences being correlated with

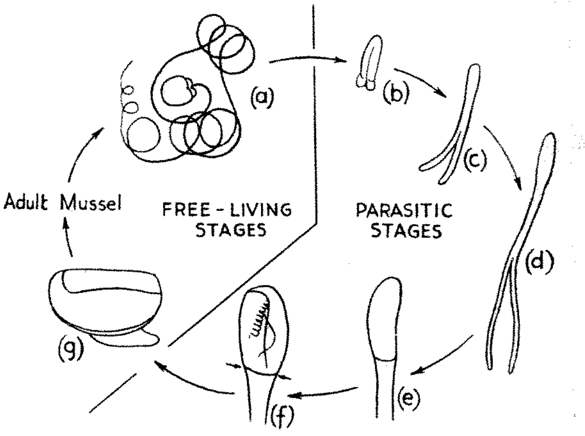

Fig. 1. Life-history of *Mutela bourguignati*. The illustrations are semi-diagrammatic and are not all drawn to the same scale

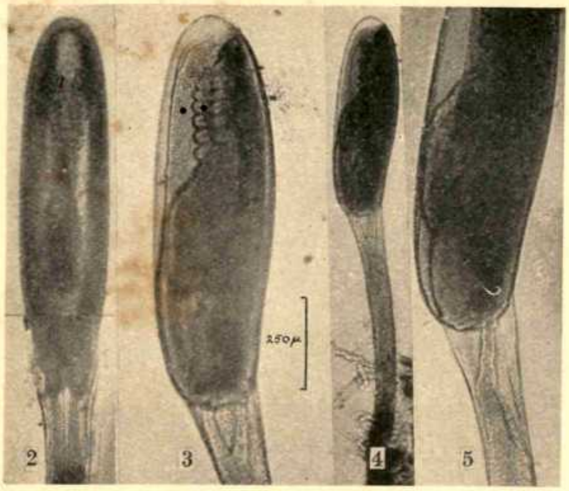

Figs. 2 and 3. Posterior (distal) extremity of fairly advanced post-larvæ in which, although still completely enclosed within the post-larval cuticle, the rudiments of certain adult organs are well defined. Fig. 4. The same specimen as that shown in Fig. 3 but showing more of the post-larval tube. (The objects adhering to the lower part of the tube are sessile ciliate protozoans which often colonize this region.) Fig. 5. Region where, at a later stage of development, the young mussel and the stalk will part company. In all the photographs, and most clearly in Figs. 2 and 5, the anterior prolongations of the mantle, which extend into the anchoring tubes, can be seen

the subsequent period of parasitism. Most remarkable of these larval features is the possession of an extremely long filamentous tentacle which resembles the tentacle of the glochidium of the Unionidae but is very much longer, being more than 70 times that of the larva itself.

These larvæ are shed through the exhalant siphons of the parent, and such as locate a host attach themselves to the cyprinid fish *Barbus altianalis radcliffi* Boulenger, usually, but not exclusively, to the fins. Attachment is probably effected initially by means of minute hooks with which the larva is provided posteriorly. After establishment on the host a remarkable transformation takes place. The tentacle is lost, and the larval shell, which at this stage consists merely of a thin pellicle and shows no signs of calcification, folds into a minute bivalved structure in which fusion occurs in the mid-ventral line to give, ultimately, a completely enclosed structure. This process is reminiscent of what occurs during metamorphosis of the Scaphopoda, but is carried even further in that both ends of the folded shell are sealed. Two outgrowths arise from the anterior end and penetrate the superficial tissues of the host (*b*). Growth of these structures results in the formation of two completely enclosed tubes (*c*) which serve as organs of attachment and through which nutritive substances are presumably absorbed from the host. With the exception of these structures the post-larva develops outside the host tissues. As a result of the fusion process described, the body of the post-larva is enclosed in a sealed tube the nature of the non-calcareous walls of which is being investigated. This tube grows to a length of about 3 mm. Within its distal extremity the adult mussel is eventually formed. Running from the distal mass of tissue through the proximal part of this tubular structure, and separated from each other by a longitudinal septum of the same material as the outer walls, are two strands of tissue which, as revealed in later stages of development (Figs. 2–5), are morphologically anterior extensions of the mantle. These extend into, and to the extremities of, the anchoring tubes. At this stage the parasitic post-larva is not only unlike a mollusc but also, from its external appearance, could easily be mistaken for a fungal hypha.

Enlargement of the distal extremity and differentiation within it (Fig. 1*d* and *e* and Figs. 2–5) results in the formation of adult organs—mantle, foot, ctenidia, adductor muscles, etc.—and the organic matrix of the adult valves begins to be formed. The periostracum is secreted from the inner face of the outer mantle fold in the manner typical of lamellibranchs. At first this primitive shell material forms a layer inside, and closely adpressed to, the post-larval tube; but subsequent growth and secretion result in a longitudinal split of the tube in that region of the post-larva where the adult structures are forming and along what will be the mid-ventral line of the adult mussel. The post-larval tube material, however, continues to embrace the rudimentary adult valves and to strengthen the ligament region (*f*). Calcareous material is deposited in the valve rudiments and the gut opens to the exterior so that, even before it leaves its host, the mussel can, and does, feed by ciliary action in the typical lamellibranch manner. At this stage, which represents the termination of the parasitic phase of the life-cycle, the organism is clearly recognizable as a typical bivalve attached to the end of a long stalk.

Rupture of the tubular outgrowth at a point near the anterior end of the newly formed valves (indicated by arrows in Fig. 1*f*) results in the release of the young mussel (*g*), which falls to the bottom and commences an independent existence. At the time of its release it has a length of rather less than 1·5 mm. The stalk remains attached to the host.

Not only is such an ontogenetic sequence highly specialized, but also both larval and post-larval stages, and particularly the latter, exhibit features which are unique within the Mollusca. Anatomical studies of the various stages of development are now in progress and a detailed illustrated description of these and a more complete account of the life-cycle will be published in due course.

Bulbil Formation in *Sedum telephium*

A vegetative plant of a species of *Sedum*, afterwards identified as *S. telephium*, was collected in a hedgerow on Rothamsted Farm on June 9, 1958, and placed with its roots in a jar containing tap water to keep it alive for further study. The jar stood on the laboratory window-sill for three months, when it was observed that, although the specimen failed to flower, bulbils had formed in the axils of the upper leaves—positions in which flowering stems would normally arise. Some axils contained several bulbils as shown in Fig. 1. Each bulbil bore scale-leaves and numerous white roots, each of which had a conspicuous dark root cap. When separated from the parent plant and placed on damp filter paper, each bulbil quickly developed into a new plant. Fig. 2*a* shows such a plant after six days growth and Fig. 2*b* after 13 days growth respectively. At the first two or three nodes the leaves were simple and opposite, but the fourth node produced irregularly dentate leaves typical of the adult plant.

Bulbil formation seems not to have been previously reported in the genus *Sedum*, although Godron[1] men-

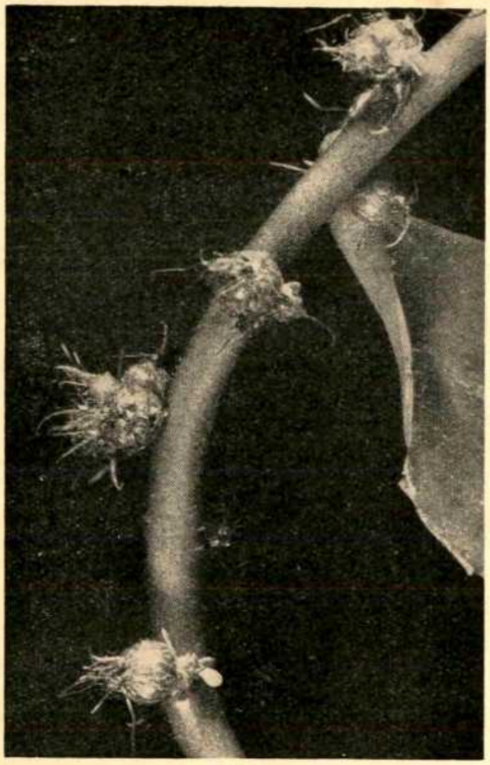

Fig. 1

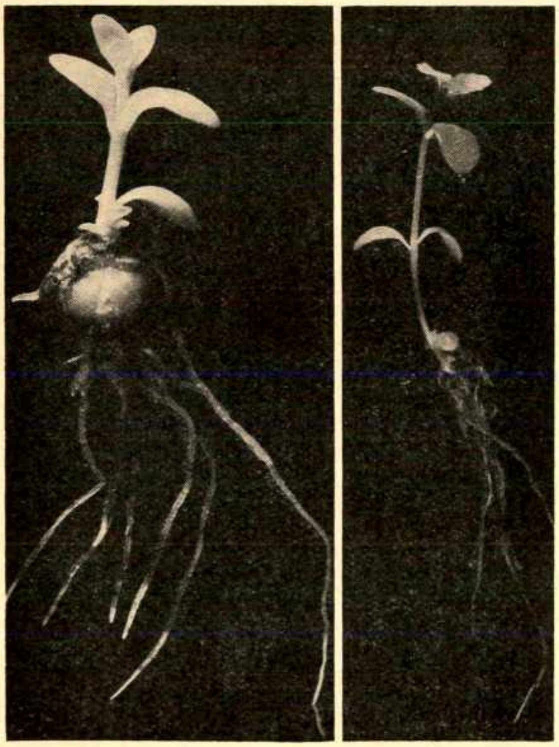
tions this genus as one containing species with the power to develop buds on the surface of the leaf. Lloyd Praeger[2], in a monograph on the genus *Sedum*, was apparently not aware of the phenomenon of bulbil formation, but points out that some of the *Telephium* section of the genus, notably *S. viviparum* and *S. verticillatum*, produce in the upper part of their annual stems numerous small leafy buds which, when the stems fall, root readily and form new plants. A somewhat similar condition occurs in *Crassula multicarva* and *C. cordata*[3], where small shoots in the inflorescence region bearing two pairs of leaves can function as organs of vegetative propagation. The bulbils described in this communication appear to be an extreme form of such shoots.



(*a*) (*b*)

Fig. 2

Why this specimen formed bulbils is uncertain, but its only supply of minerals was from a small amount of tap water. The possible relationship between bulbil formation and nutrition will be further studied in experiments using solutions of known mineral content.

Ecology of *Mucor ramannianus* Moller

Mucor ramannianus is one of the commonest fungi occurring in certain acid, sandy soils, and often, in some horizons, may be the only fungus isolated by standard plating methods. In grassland soils at Lakenheath Warren it was confined to those of low *p*H value[1], and Thornton[2] found it to be very common in podsolized soils beneath *Calluna vulgaris* L., but absent from soils of similar derivation beneath mixed oakwood. *M. ramannianus* was a characteristic fungus in six out of nine acid, heath soils examined by Jefferys, Brian, Hemming and Lowe[3], who suggested that its presence was related to the existence of a well-marked iron-pan in the *B* horizon. McLennan and Ducker[4,5] have further suggested that a predominance of *M. ramannianus* is indicative of acid, sandy soil types with a well-defined pan layer. Detailed studies, primarily of a physiological nature, have been described by Müller[6], who concluded that not only the presence of growth factors but also the hydrogen ion concentration of the soil and source of carbon would play an important part in limiting its distribution. *M. ramannianus* was among the commonest species encountered by us in soils and on roots during detailed surveys of the mycofloras of some British dune systems[7] and *Calluna*-heathlands[8]; its distribution was closely related to certain soil conditions which are discussed below. These observations are presented in view of the fragmentary and sometimes conflicting data available on the ecology of this interesting species.

The succession of soil fungi from open sands of the shore to fixed dune in Britain typically culminates in a community resembling that of acid heathland or alkaline grassland. *M. ramannianus* was isolated by the soil plate method[9] from one or more of the acid semi-fixed or fixed zones in all such dune systems investigated, but from none of the alkaline or young acid dunes. The acid dune zones in which *M. ramannianus* attained a frequency of at least 50 per cent were dry dune-heaths dominated by *Ammophila–Carex–Calluna*, *Calluna*, or *Calluna–Pteridium* communities.

M. ramannianus was present in all but two of fourteen distinct inland *Calluna*-heath soils from six counties of England and Wales, but was of very infrequent occurrence in several of these. There was a marked relationship between its frequency of occurrence and the moisture relations of the habitat as indicated by the surface vegetation; indeed, *M. ramannianus* appeared to be less tolerant of wet conditions than *Calluna* itself, and was of infrequent occurrence or absent from soils where plant communities indicating damp soil conditions occurred, that is, *Calluna* in association with *Molinia*, *Erica tetralix* and *Salix repens*.

In both acid dune and inland heath soils the frequency of occurrence increased with depth to a maximum in the humus-poor or leached, subsurface sands. Within the acid dune succession the first distinct subsurface population was found in the dune heath profiles when *M. ramannianus* and *Penicillium restrictum* were characteristically associated together at a soil depths of 6–12 in., often in the absence of other species. Similarly, in dry, inland heaths, *M. ramannianus* was characteristically predominant in specifically poor mycofloras of the A_2 horizons. The lower limit of vertical distribution in dune heaths was often clear-cut although the sand above and below it appeared similar. This phenomenon was occasionally observed in inland heaths where the water-table was near the surface; but in heath soils lacking vertical zonation, *M. ramannianus* was generally present at all depths sampled, and in podsolized soils its vertical distribution was sharply checked at the illuviated horizons. The low frequency of isolation of *M. ramannianus* from surface soils may have resulted from the vigorous competition of other species on plates prepared from these soils. Early excision, from soil plates, of fungi with a rapid and spreading growth habit did not, however, result in an increase in the number of *M. ramannianus* colonies.

Root isolation studies, employing a root washing device similar to that described by Simmonds[10], indicated that *M. ramannianus* was a common and active root-surface inhabitant. It occurred with frequencies of 25 per cent and 50 per cent on *Ammophila* roots from the A_1 and subsurface soils respectively in acid-fixed dunes, but was not recorded on such roots from the fore-dunes. The fungus was also very common on *Calluna* roots from the A_2 and B_1 horizons of an inland dry heath soil. Thrower[11], however, has concluded, from the studies of the rhizospheres of Australian heath plants, that *M. ramannianus* was predominantly an inhabitant of the free soil and infrequent in the root region.

Our investigations indicate that *M. ramannianus* is a prominent member of acid, semi-fixed and fixed dune heath and inland dry heath communities. Since it was isolated readily by a modified slidetrap method[12] from both types of habitat, it is probable that the fungus commonly exists as an active mycelium in these soils. The calcifuge habit of *M. ramannianus* was indicated by its intolerance of alkalinity in culture media, where growth and sporulation were at a maximum at *p*H 3–4 and sparse at *p*H 7 (Brown[7]) and by its absence from calcareous dune systems. A similar influence of hydrogen ion concentration on its growth has also been demonstrated by Müller[6]. The distribution of *M. ramannianus* in a wide range of heathland soils and its absence from wet dune lows and slacks indicated an intolerance also of damp soil conditions, or some other associated factor. (It should be noted that neither of these factors appears to be completely limiting since Stenton[13] isolated *M. ramannianus* from slightly alkaline, peaty soil at Wicken Fen.) Throughout the investigations there was no indication that the occurrence of *M. ramannianus* was related to the presence of illuviated horizons in the soil profiles, as has been suggested by Jefferys *et al.*[3] and McLennan and Ducker[4,5]; indeed, the results presented by Jefferys *et al.* may be interpreted in relation to soil moisture status (as judged by the nature of the surface flora) as readily as to the presence of a well-marked iron-pan in the *B* horizon.

Perfect Stage of *Keratinomyces ajelloi*

Keratinomyces ajelloi was first described in 1952 by Vanbreuseghem[1], who isolated it from soil by means of a technique[2] which consists of placing hair on the surface of the soil in a Petri dish as 'bait' for keratinophilic fungi. Since this original isolation, the fungus has been reported many times and is clearly a common inhabitant of soil and of widespread distribution.

Recently, fourteen samples of soil from eight districts in Glasgow and the west of Scotland were investigated for keratinophilic fungi. *K. ajelloi*, in most cases with certain other keratinophilic fungi, was isolated from thirteen samples. The remaining sample did not contain any keratinophilic fungi.

The soil samples were collected into polythene bags from the top 4 in. of cultivated land or immediately beneath the turf of fallow land and processed within a few days. Essentially the technique employed was that of Vanbreuseghem; but the soil was baited with horse mane or tail hair, child's hair, shreds of cow horn and feathers, as well as with adult human hair. The Petri dishes were incubated at 28° C. and examined at intervals over a period of 5–6 weeks.

K. ajelloi could be identified by microscopic examination, and inoculations made for culture as early as one week after baiting. By the end of the

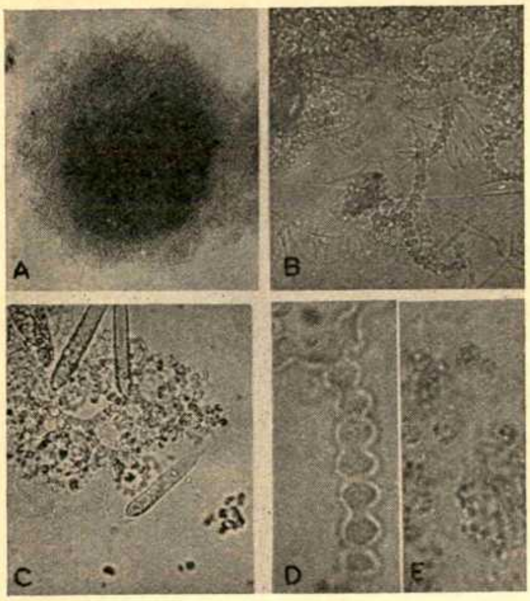

Fig. 1. *A*, mature cleistothecium, mount lactophenol (× 65); *B*, peridium showing characteristic branching and spiral appendages, mount cotton blue in lactophenol (× 265); *C*, macroconidium formed from peridial hyphæ, mount lactophenol (× 250); *D*, cells of peridial hyphæ (× 625); *E*, asci (× 625)

third week, creamy yellow globose structures had developed on certain of the baits on the surface of seven of the soil samples from three districts. Microscopic examination revealed these to be cleistothecia. They were closely associated with *K. ajelloi*, and it was shown by culture of complete cleistothecia and of single ascospores that they were in fact the perfect stage of this fungus. There was no evidence of sexual reproduction in the six isolates of *K. ajelloi* from the soil of the remaining four districts.

The cleistothecia (Fig. 1*A*), which measure 300μ–900μ in diameter, have a peridium of pale yellow hyphæ with a characteristic pattern of claw-like branches (Fig. 1*B*) entangled to form a close network. The individual cells (Fig. 1*D*) are dumb-bell shaped with thick echinulate walls and many of them bear long, smooth-walled spiral appendages (Fig. 1*B*) or occasionally macroconidia of the characteristic *Keratinomyces* form (Fig. 1*C*). The asci (Fig. 1*E*) which are formed in large numbers are sub-globose, and each contains eight bright yellow ascospores with finely echinulate walls.

Sexual reproduction is apparently influenced by a number of factors. It was never observed in culture on agar media, and on primary isolation cleistothecia were formed regularly on only certain of the keratinaceous baits. On horse hair and child's hair they were always produced abundantly, whereas on adult human hair on the same soils they formed sparsely on only one occasion after an incubation period of 6–8 weeks.

A number of attempts were made to ascertain the conditions necessary for sexual reproduction. Complete cleistothecia were inoculated on autoclaved horse hair which was maintained in a humid atmosphere; but a few cleistothecia were produced on only two of the many occasions on which this was done. Unsatisfactory results were also obtained from a large series of experiments in which sterilized soil previously inoculated with cleistothecia or with agar cultures was baited with horse hair. Eventually regular sexual reproduction on horse-hair bait was achieved by inoculation of unsterilized soil with cultures of cleistothecial strains. For this purpose the soil known to be negative for keratinophilic fungi was used. Attempts were then made to induce sexual reproduction in those strains which had not formed cleistothecia when isolated originally. They were inoculated singly and in combination with one another or with single ascospores strains into the unsterilized negative soil baited with horse hair. However, cleistothecia were never formed. Three single ascospore cultures (*A*, *B* and *C*) were also treated in this way. Cleistothecia formed regularly in all the Petri dishes inoculated with strain combinations *AB* and *AC* but not with combination *BC* or with single strains.

It would therefore appear that *K. ajelloi* is heterothallic and that compatible strains will reproduce sexually under certain conditions which are fulfilled by certain keratinaceous baits on the surface of unsterilized soil. However, certain strains may have lost their ability to reproduce by sexual means. In this small series it has been noted that those strains which were 'non-cleistothecial' on original isolation and in which cleistothecial formation could not be induced failed to produce the typical vinaceous red pigment when grown on glucose peptone agar. All cleistothecial strains formed pigment, as did the monospore cultures. There is, as yet, insufficient evidence to assume that pigment production is indicative of ability to reproduce sexually, but this and other aspects are being further investigated.

We are indebted to Mrs. E. Forbes for assistance with minospore isolations and to Miss E. Brown for technical assistance.

Inactivation of Organo-Mercurial Fungicides in Groundwood Pulp made from Logs stored in Salt Water, and the Possible Role of Sulphur Compounds

RECENT experiments conducted in our laboratories have shown that there is a correlation between the efficiency of organo-mercurial fungicides, used for the preservation of moist groundwood, and the concentration of certain sulphur compounds in the logs from which the groundwood is produced. These sulphur compounds are considered to arise from the reduction of inorganic sulphates, absorbed from salt or brackish water during storage, by halophilic strains of *Desulphovibrio desulphuricans*. These bacteria have been isolated from the sapwood of logs stored under natural conditions in sea water for a year. Chemical and microbiological studies have been made on samples of pulp, and on logs obtained from a number of Scandinavian groundwood mills after storing for different periods in fresh water, brackish water and sea water. In every case high sulphur contents, expressed as sulphidic and reducible[1] sulphur, were found both in pulp samples containing biologically inactive fungicide and in the sapwood of the logs from which they had been made. Conversely, pulps having a high residual content of biologically active fungicide (and consequently a good record of freedom from fungal infection during storage) contained considerably less sulphidic and reducible sulphur, as did the corresponding logs. The latter logs and groundwood pulps came from mills where the wood is stored for 1–2 years in fresh water prior to grinding; the former from mills on or near the coast where the logs are kept in sea water or brackish water for similar periods of time. It has, in fact, been found that after only three months soaking of logs in sea water, mercurial fungicides are de-activated at once on addition to the resultant pulp. It has been shown in the laboratory that the de-activating property progresses farther into the heart of the log with increasing length of immersion.

(In this work sulphidic sulphur has been defined as hydrogen sulphide liberated by hydrochloric acid, and reducible sulphur as sulphur present in the sample and reducible, under the conditions of test, to hydrogen sulphide.)

Sea water itself has been shown to have no adverse effect on either phenyl mercuric acetate or phenyl mercuric acetate-8-hydroxyquinoline (P.M.A.-oxine) mixtures. Thus, from these observations and the presence of *D. desulphuricans*, the inference may be drawn that the absorption by logs of inorganic sulphates is followed by reduction to certain sulphur compounds, which are able to bring about the formation of biologically inactive mercury compounds when the fungicide is added to the pulp. The interaction between mercury and its salts and hydrogen sulphide produced in soil by the bacterial reduction of sulphates has been reported by Booer[2]. Whatever the precise mechanism of this final step may be, the de-activating effect has been found to be immediate with both commercial and laboratory-made pulps derived from sea water-soaked logs.

The exact forms in which these sulphidic and reducible sulphur compounds are present in the wood (or pulp) is still being investigated; it is possible that hydrogen sulphide liberated by bacteria may react to form thiolignin[3] and this point is under investigation.

A detailed account of this work will eventually be published elsewhere.

GENETICS

Stable Equilibrium at a Sex-linked Locus

Bennett[1] has shown that a stable selectively balanced polymorphism between two alleles can exist at a locus in the X-chromosome under conditions which are different from those determining stable equilibrium in the autosomal situation. In particular, it is neither necessary nor sufficient, in the sex-linked case, for the heterozygote in the homogametic sex to be at a selective advantage with respect to both homozygotes. It has previously been found[2] that this principle of heterozygosity operates in the case of multiple allelic systems in autosomes in the following form: a necessary condition for stable equilibrium is that the viability of each homozygote be less than the mean viability of the zygotic population at equilibrium. It seems at first sight that no such heterozygosity principle operates in the sex-linked situation. It will, however, be shown here that it does do so in a somewhat modified form.

It is convenient here to use homogeneous parameters to express relative viabilities, rather than Bennett's method of expressing them relative to the viability of the heterozygote. Thus we may have, for two alleles A,B (taking females as the homogametic sex):

	Females			Males	
Genotype Relative viability	AA a	AB h	BB b	A a^*	B b^*

In any one generation let the frequencies of A,B be p,q respectively in females, and p^*,q^* respectively in males, so that:

$$p + q = 1, \quad p^* + q^* = 1 \tag{1}$$

Then in the next generation (after random mating) we obtain genotypic frequencies as follows:

	Females			Males	
Genotype	AA	AB	BB	A	B
Frequency before selection (zygotes)	pp^*	$pq^* + p^*q$	qq^*	p	q
Frequency after selection (mature adults)	$\frac{app^*}{T}$	$\frac{h(pq^* + p^*q)}{T}$	$\frac{bqq^*}{T}$	$\frac{a^*p}{T^*}$	$\frac{b^*q}{T^*}$

$$\left.\begin{aligned} \text{where } T &= app^* + h(pq^* + p^*q) + bqq^* \\ T^* &= a^*p + b^*q \end{aligned}\right\} \tag{2}$$

For equilibrium of the gene frequencies in the two sexes the gene ratios must have the values:

$$\text{in females: } R = \frac{p}{q} = \frac{h(a^* + b^*) - 2bb^*}{h(a^* + b^*) - 2aa^*} \tag{3}$$

$$\text{in males: } R^* = \frac{p^*}{q^*} = \frac{a^*}{b^*} R \tag{4}$$

Moreover, the equilibrium is stable if and only if the conditions:

$$\frac{h(a^* + b^*)}{2} > aa^*, \quad \frac{h(a^* + b^*)}{2} > bb^* \tag{5}$$

are satisfied.

It is clear from (3) and (5) that for the homogametic sex the conditions determining equilibrium and its stability are identical with those governing two alleles A,B at an autosomal locus in which the relative viabilities of the genotypes AA, AB, BB are

$$a' = aa^*, \quad h' = \frac{h(a^* + b^*)}{2}, \quad b' = bb^* \text{ respectively.}$$

If we now consider females only with the modified relative viabilities a', h', b', the principle of heterozygosity emerges in the following way. The mean viability V_e of female zygotes at equilibrium can be written:

$$V_e = a'pp^* + h'(pq^* + p^*q) + b'qq^* \tag{6}$$

where p, q, p^*, q^* satisfy (1), (2) and (3).

Now,

$$V_e = a' + \left\{(b' - a') + (h' - a')R\left(1 + \frac{a^*}{b^*}\right)\right\}qq^*$$
$$= a' + \left\{(h' - a') + \frac{a^*}{b^*}(h' - b')\right\}qq^*$$

using (2) and (3).

If the equilibrium is stable then (5) holds also and we have:

$$V_e > a' = aa^* \qquad (7)$$

and similarly: $V_e > b' = bb^*$ (8)

These conditions are necessary for the existence of a stable equilibrium, and constitute the heterozygosity principle in its modified form.

It is worth while noting a second form of the new heterozygosity principle which in the case of an autosomal allelic system has proved a valuable interpretative guide. In the present case the second form of the principle is entirely equivalent to either of the formulations given above, namely, (i) $h' > a', b'$; (ii) $V_e > a', b'$.

If in the mature females the genotypic frequencies of AA, AB and BB are u, v and w respectively, then under random mating without selection the index:

$$\varphi = \frac{v^2 - 4uw}{(2u + v)(v + 2w)} \qquad (9)$$

(which is in fact minus the inbreeding coefficient F) is zero.

In the polymorphism considered here, φ is equal to a positive multiple of:

$$h^2(R + R^*)^2 - 4abRR^* = R^2\left\{h^2\left(1 + \frac{a^*}{b^*}\right)^2 - 4ab\frac{a^*}{b^*}\right\}$$
$$= \frac{4R^2}{b^{*2}}\left\{h'^2 - a'b'\right\}$$

and this is positive by the conditions (5) for stability. This indicates that a condition for stability is that the female heterozygotes are present in excess of Hardy–Weinberg expectations. Thus the principle of heterozygosity holds in this case in a very definite and graphic form.

The above treatment of a sex-linked locus in terms of the autosomal case can be extended to multi-allelic loci in the X-chromosome. This will be discussed elsewhere.

I wish to thank Dr. A. R. G. Owen for suggesting this problem and for much helpful advice and encouragement; and the Royal Commission for the Exhibition of 1851 for the award of an Overseas Science Research Scholarship.

Congenital Transmission of Toxoplasmosis through Successive Generations of Mice

CONGENITAL transmission of infectious agents—viruses, rickettsiæ, spirochætes and piroplasms—is not uncommon in arthropods and may pass through many generations. It is much less common in mammals in which, when it occurs, it usually stops at the second generation. In mice, however, the virus of lymphocytic chorio-meningitis can be transmitted indefinitely[1], and there are claims that in man syphilis can pass to the third generation[2].

The protozoon *Toxoplasma* was reported by Wildfuhr[3] to have been congenitally transmitted to the third generation of rats. Recently, I have observed its transmission to successive generations of mice—five so far.

The experiments started with infection by subcutaneous inoculation of Swiss mice, six between the eighth and sixteenth days of pregnancy, one 2 days after a mating, which did not result in obvious pregnancy, and one 5 days after delivery. The inoculation consisted of between 30 and 600 cysts of a strain of *Toxoplasma* of low virulence (rabbit A), originally isolated from a naturally infected, but apparently healthy, laboratory rabbit. Although congenital infection with the strain shortens the lives of mice, reduces the number of litters they produce and the number reared to maturity in each litter, artificial inoculation does not make them obviously sick unless done during pregnancy or lactation. To this may be ascribed the heavy mortality in most of the first litters of the original mice, as a result of which in only one of these did a female survive to continue the line. In the other instances the lines derived from second litters.

All eight mice transmitted *Toxoplasma* infection to some of the second generation. Two lines of infection stopped there; one because the only infected female of the second generation proved infertile and the other because the one surviving female was killed when a very low antibody titre was, erroneously, taken to signify absence of infection. Four continued to the third generation at which one stopped because only males were infected and two because the females did not become pregnant. The fourth still goes on. Also continuing, and infected, are one line in the fourth and one in the fifth generations.

In all there have been 33 first or subsequent pregnancies in the original mice or their descendants. Except in three of these pregnancies, some of (on average half) the litter have been infected.

The presence of infection in a litter was determined by killing the males when 6 weeks old, making emulsions of their brains and examining them for *Toxoplasma* cysts. If these were found, the females were reared for a further 4 weeks and then mated to non-infected males. Before this their blood serum was in some instances examined for *Toxoplasma* antibodies, and when they were eventually killed all their brains were examined for cysts.

It would seem likely that infection is transmitted, for the most part, before birth, for toxoplasms were isolated by inoculation of surgically removed fœtuses into uninfected mice.

Of course it can also be transmitted by the milk, as shown by Eichenwald[4]. This I can confirm as the result of experiments in which mice were inoculated during lactation. Infection does not appear to be transmitted by droplet, fæces, urine or by copulation, for 10 female mice and their 33 litters, comprising 216 offspring, did not acquire infection from 10 infected males with which they were caged for 4–8 months.

There are many puzzling features in *Toxoplasma* infection of laboratory mice. Natural infection is fortunately almost unknown, yet mice are very susceptible to inoculation, to intranasal instillation of proliferative forms, or to feeding with cysts. Cannibalism is the only way yet known by which adult mice can be infected naturally, yet when infection is established it passes fairly readily from generation to generation. Nor is it necessary, as Eichenwald[4] believed, for infection to be recent and acute. Twenty-three of the infected litters were borne of mothers themselves congenitally infected, and in one instance a congenitally infected mother produced congenitally infected offspring even in her fourth litter.

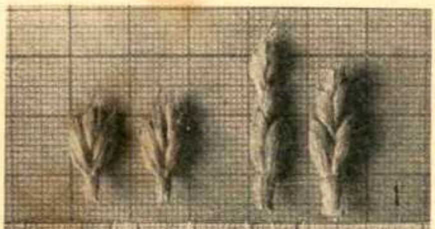
An Induced Mutant in *Triticum carthlicum* with the Diagnostic Feature of *T. vavilovi*

THE spike of *Triticum vavilovi* Jakub. is distinctive in that the internodes of the rachilla are more elongate and the number of rachilla nodes increased compared with other hexaploid wheats. The elongated rachilla internodes sometimes so reduce the extent to which the florets overlap as to give the spikelet two or three distinct levels (Fig. 1).



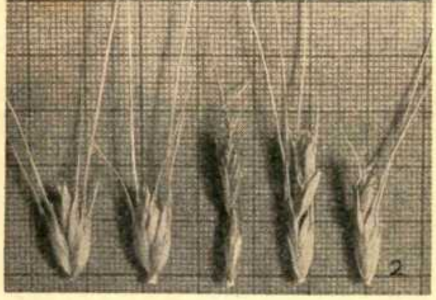


Fig. 1. Two *T. aestivum* normal (left) and two *T. vavilovi* spikelets with several levels (right)

Fig. 2. Two *T. carthlicum* normal (left) and three *T. carthlicum* mutant spikelets (right) with several levels

In 1955, as part of a larger programme, dry seed of genetically pure *T. carthlicum* Nevski (= *T. persicum* Vav.), a tetraploid wheat, was treated with a dose of 10,000 r. X-rays. In the X_3 generation, examined in 1957, a mutant was found which strikingly resembled *T. vavilovi* (Fig. 2). This type had not been present in the X_1 or X_2 generations, but 21 plants in the X_4 progeny of the mutant plant all repeated the mutant structure.

The most important divergences of this mutant from the original *T. carthlicum* stock are compared in Table 1 with the differences between *T. vavilovi* and *T. aestivum* var. Newthatch, the hexaploid common wheat. The total extent of the difference between the *T. carthlicum* mutant and the parental stock is readily ascertainable but the extent of the original difference between *T. vavilovi* and *T. aestivum* cannot be exactly determined because of the present variation in the latter species. The two species are constantly differentiated only by the characters listed in Table 1. Many of the spikelet types seen in the investigation of the genetical constitution of *T. vavilovi* by Singh, Anderson and Pal[1] were observed in this relatively small range of mutant material.

Table 1

Character	Hexaploids		Tetraploids	
	T. aestivum	*T. vavilovi*	*T. carthlicum*	Mutant
Spike	normal	pseudo branch	normal	pseudo branch
Spikelet number of levels	1	2, sometimes 3	1	2, sometimes 3
Rachis at the spikelet bases			glabrous	pubescent
Rachilla number of nodes	5	7	5	7
Internodes	short	elongated	short	elongated
Glume, outer glume			bearded	beardless, with beak-shaped end
Inner glume, arista			long	shorter

According to Isenbeck and Rosentiel[2], Vavilov does not touch upon the genetical bases of *T. vavilovi*. Isenbeck and Rosentiel suggest that the development of this form may be explained as a one-step mutation from *T. aestivum*. This explanation is not excluded by the data of Singh, Anderson and Pal[1] from crosses between *T. vavilovi* and several *Triticum* species. Further, it appears that there is no genome difference between *T. aestivum* and *T. vavilovi*. This hypothesis is confirmed, at the tetraploid level, by a mutant analogous with *T. vavilovi* which actually originated in a single mutational step. In this case of parallel mutations, it may be supposed that since the final outcome was identical the pathways were also identical.

The genetic foundations of the mutant in *T. carthlicum* will only be established by crossing experiments already commenced. The mutation of a single gene to the recessive condition would be the most simple explanation for segregation occurring in X_3 and for the mutant to be true breeding in X_4.

Summing up, the 'vavilovoid' mutant may be of interest in that it illustrates parallel variation and parallel genotypes at the tetraploid and hexaploid level. Moreover, it throws light on the origin of *T. vavilovi* and confirms the supposition of Isenbeck and Rosentiel. Finally, it raises a taxonomic problem, namely, that if *T. vavilovi* is treated as a distinct species as classified by Vavilov[3], by Jakubsiner[3] and by Singh, Anderson and Pal[1], then it must be accepted, at the tetraploid level, that a new species arose from *T. carthlicum* in a single mutational step. Alternatively, if *T. vavilovi* is treated as a subspecies of *T. aestivum*, as it is classed by Sears[4] and by Schiemann[4], subspecific variation must have originated in a single step.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 11

University of London (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 5 p.m.—Dr. G. C. Ainsworth: "The Fungus".* (First of three Special University Lectures on Fungous Diseases of Animals". Further lectures on May 12 and 14.)

University of London (at the Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, London, W.2), at 5 p.m.—Prof. G. W. Beadle (California Institute of Technology): "The Molecular Basis of Heredity".* (Last of a series of four Almroth Wright Lectures.)

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. J. B. Neilands (California): "Iron Metabolism in Micro-organisms".*

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. G. Gorer: "The Concept of National Character".

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Dr. H. Lowery: "Gilbert White and His 'Natural History of Selbourne' ".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Trends in the Teaching of Electric Machine Theory in the United States", opened by Mr. P. L. Alger.

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. Eric Shipton, C.B.E.: "Explorations in Patagonia".

Monday, May 11—Wednesday, May 13

Institution of Chemical Engineers; Society of Instrument Technology; and the British Computer Society (at the Central Hall, Westminster, London, S.W.1)—Joint Symposium on "Instrumentation and Computation in Process Development and Plant Design".

Tuesday, May 12

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Annual General Meeting, followed by a full-day Meeting on "The Manuring of Tropical Crops".

University of London (at the London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Dr. Frederick Barth (Oslo): "The Anthropological Study of Middle Eastern Societies".*

University of London (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 5 p.m.—Dr. G. C. Ainsworth: "The Fungus and the Host".* (Second of three Special University Lectures of "Fungous Diseases of Animals". Further lecture on May 14.)

University of London (in the Physiology Lecture Theatre, Guy's Hospital Medical School, London Bridge, S.E.1), at 5 p.m.—Sir George Thomson, F.R.S.: "The Principles of Physics" (Fison Memorial Lecture).

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Parliamentary and Scientific Committee, General Committee (in the Grand Committee Room, Westminster Hall, House of Commons, S.W.1), at 5.30 p.m.—Discussion on "Modern Techniques and their Application to and Influence on New Buildings" opened by Mr. Norman Wates and Mr. Anthony Pott.

Society of Chemical Industry, Chemical Engineering Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. W. Quick: "Fuel Economy in Chemical Works".

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Prof. J. D. Evans: "The Animal World of Prehistoric Farmers and Pastoralists in Europe".* (Second of six lectures on "Animals in Archæology". Further lectures on May 19, 26, June 2 and 9.)

British Computer Society (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. T. C. Hickman: "Early Experience with an E. D. P. Installation".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Mr. N. J. Van Abbe: "Pharmaceutical Aspects of Dermatological Treatment".

Wednesday, May 13

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. E. F. Gale: "Disorganization of the Bacterial Cell by Antibiotics".*

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), from 2.30 p.m.–6 p.m.—Discussion on "The Dynamics of Cumulonimbus". Opening Speakers: Dr. R. S. Scorer, Mr. P. M. Saunders, Mr. F. H. Ludlam and Mr. W. G. Harper.

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. F. Dixey: "The Geomorphology of Madagascar".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Hans Helbaek (Copenhagen): "Archæology and the Evolution of the Cultivated Plants, with special reference to *Linum*".

University of London (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. R. W. Riddell: "Aspergilli as a Cause of Pulmonary Disorders".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. E. G. Rowe: "The Application of Statistical Techniques to the Electric Valve Industry".

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Scientific Papers (Seventh Young Members' Meeting).

Society of Instrument Technology, Data Processing Section (at Manson House, Portland Place, London, W.1), at 6 p.m.—Annual General Meeting, followed by Mr. J. R. Sturgeon: "A Multipoint Digital Strain-Gauge Recorder".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. D. Gabor, F.R.S.: "Improving Communication Techniques—What Have Engineers to Learn from Information Theory ?".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. G. Kitson Clark: "The Modern State and Modern Society: Historic Tendencies and Future Probabilities".

Thursday, May 14

Association of Agriculture (at 53 Victoria Street, London, S.W.1), at 11.30 a.m.—Annual General Meeting.

University of London (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 5 p.m.—Dr. G. C. Ainsworth: "The Fungus, the Host, and the Environment".* (Last of three Special University Lectures on "Fungous Diseases of Animals".)

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Annual General Meeting. 6.30 p.m.—Prof. E. C. Cherry: "On the Conceivable Future of Telecommunications".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, London, S.W.1), at 6 p.m.—Mr. C. J. McCarthy: 47th Wilbur Wright Memorial Lecture.

Institute of Biology (at Brunel College of Technology, Woodlands Avenue, Acton, London, W.3), at 7.30 p.m.—Dr. L. G. C. E. Pugh: "Men at High Altitudes".*

Friday, May 15

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Captain E. G. Irving, O.B.E., R.N.: "Electronic Surveys in the Caribbean".

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Annual General Meeting. 7 p.m.—Dr. H. T. Openshaw: "New Developments in the Chemistry of Emetine and Related Alkaloids".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Librarian (with a good honours degree and experience in an academic library)—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 16).

Lecturer and an Assistant Lecturer in the Department of Physics—The Registrar, The University, Nottingham (May 16).

Lecturer or Assistant Lecturer (with a good honours degree in physics) in Physics—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1 (May 21).

Assistant Lecturer in Geography—The Registrar, The University, Sheffield (May 23).

Assistant Lecturer or Lecturer (preferably with interests in applied mathematics) in the Department of Mathematics; and a Temporary Assistant Lecturer or Temporary Lecturer (preferably with interests in applied mathematics) in the Department of Mathematics—The Secretary, University College, Gower Street, London, W.C.1 (June 1).

Lecturer (preferably with an interest and experience in the field of electrical machinery) in Electrical Engineering—The Deputy Registrar, The University, Birmingham 15 (June 1).

Assistant Experimental Officer (with a degree in a biological subject and practical experience in bacteriological methods and techniques) for work on the ecology of soil micro-organisms—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (June 30).

Senior Lecturer in Mathematics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, (June 30).

Chair of Engineering—The Registrar, The University, Leicester.

Senior Lecturer (with good academic qualifications, teaching experience and preferably special qualifications or experience in mathematical statistics or other branch of applied mathematics) in Mathematics—The Registrar, Hatfield Technical College, Hatfield.

"The Infrared Spectrum . . . ."

"The infrared spectrum of a chemical compound is probably the most characteristic physical property of that compound."* From this fact has grown to-day's dependence on infrared analysis for rapid, complete information on the structure and composition of nearly all chemical compounds.

A parallel development in infrared instrumentation has reached its peak in the Unicam SP.100 Infrared Spectrometer which offers a unique combination of performance and utility. Both technical and commercial management in many fields have been quick to recognise a powerful tool in the search for a better product—or a better way of making existing ones.

Write for a detailed description of the SP.100 Spectrometer and for a copy of a new leaflet "Economics of Infrared" which indicates some of the ways infrared spectroscopy can help a lively business keep ahead.

NUCLEAR DISARMAMENT

IT would be an exaggeration to describe the debate on nuclear disarmament in the House of Lords on February 11 as a dissertation on Lord Russell's book*, but seldom have so many speakers in a debate referred so freely to a single book. The motion under debate was primarily concerned to discourage further Powers from manufacturing or owning nuclear weapons, and to this end Lord Simon of Wythenshawe proposed that Britain should cease herself to manufacture nuclear weapons and should destroy her stocks, provided other industrial nations except the United States and the U.S.S.R. themselves undertook not to own, manufacture or use such weapons. The United Nations would be asked to accept responsibility for inspection and enforcement, and the United States and the U.S.S.R. would be urged to help the United Nations and to undertake not to supply nuclear weapons to another country.

Lord Russell himself supported the motion, but put it in the larger context which his book supplies, and stressed the tendency to under-estimate the evils that would result from a really serious nuclear war. That is the starting point of his argument: these evils are so great that national self-interest itself demands the avoidance of nuclear war. A large-scale nuclear war would be an utter disaster to all mankind, including the belligerents, and would achieve no result that any sane man could desire. There is, moreover, considerable risk that a small war may develop into a great war, and even if existing nuclear weapons had been destroyed and there were an agreement that no new ones should be manufactured, any serious war would become a nuclear war as soon as the belligerents had been able to manufacture the forbidden weapons.

Thus far, Lord Russell can fairly claim to be writing common sense on nuclear warfare, though experience in regard to gas warfare seems to invalidate his last point. It was, nevertheless, made in the Vienna Declaration adopted by the participants in the Third Pugwash Conference at Kitzbuhel and Vienna in September 1958, as was noted in the debate in the House of Lords, and it must be conceded as a possibility. The instinct to survive could lead any nation to disregard any agreement or undertaking, even when the common interest of survival as well as the desire to escape from the crushing burden of the arms race make the elimination of war a matter of plain self-interest.

While, however, Lord Russell writes very cogently and reasonably about the steps to be taken towards peace and the new outlook needed before negotiations can hope to succeed, reason sometimes fails to take account of realities, not to mention difficulties. He believes that impartial agreements could be reached once both sides recognize that it is more important to reach agreement than to win diplomatic victories, and he sees some hope in the reduction of vituperation, though he points out also that propaganda should increasingly be directed to the promotion of the awareness of common humanity. He stresses the importance of government agreement on the abolition of nuclear tests as a first step towards peace, and with the resumption on April 13 of the Geneva conference on ending nuclear tests it should soon be clear how far both sides truly desire agreement. Mr. Selwyn Lloyd's reply in the House of Commons on April 15 indicates that an attempt is being made to meet the Russian objections to inspection by international teams and to utilize the opportunity which a system of control by 180 static posts might offer. The U.S.S.R. is already prepared to accept the manning of five of the ten key positions in each static post by nations of the other side, and the Western view is that one-third of the key posts should be filled by staff from the three nuclear powers and the remainder filled by the host country.

The difference between a demand for five and one for six or seven does not seem wide, but Lord Russell's second step is less simple. He suggests that the next step should be a solemn joint declaration by the United States and Soviet Russia to the effect that they will seek to settle their differences otherwise than by war or the threat of war, and that to implement this declaration they should appoint a permanent joint body to seek measures tending towards peace and not altering the existing balance of power. Lord Russell suggests that this body should be invited to study every dispute that might arise, and to suggest such settlements as each side might be willing to accept.

Nowhere, however, does Lord Russell indicate precisely what advantage such a body would offer over those already in being, given indeed the new outlook that he commends, which indeed is essentially a re-appraisal of what national interests really involve. Moreover, the problems to come before the new body are essentially questions of disarmament and territorial questions. On the former, Lord Russell adds nothing new and points out that disarmament is really a palliative rather than a solution of the problem of world order—rather a sequence of improved international relations than a cause of better relations. The actual steps towards conciliation which he proposes, however, seem to ignore the real difficulties and, to say the least, in suggesting the appointment of a conciliation committee to explore measures for diminishing tension, it is more than a little naïve to suggest that all policy makers in the modern world are too busy to acquaint themselves with the facts upon which policy should be based. On territorial adjustments, he observes that the countries of Europe should be freed from alien forces and their immunity guaranteed, but he does not indicate by whom, though he is realistic enough to regard the withdrawal of American forces from

---

* Common Sense and Nuclear Warfare. By Bertrand Russell. Pp. 94. (London: George Allen and Unwin, Ltd., 1959.) Cloth, 7s. 6d.; Paper, 3s. 6d.

Western Europe as impracticable save as a sequel to an enforceable agreement for abolishing nuclear weapons. Applied to the Far East, his suggestions completely disregard his own principle of respecting the wishes of the inhabitants and we are given no clue as to how friction, uncertainty and rivalry in difficult regions can be eliminated or by whom an international authority with power to enforce its decisions could be created. Indeed, Lord Russell admits that for the present this is an academic creation and appears to visualize it as developing from a series of subordinate federations in such a federal world as Lord Curtis advocates. Ultimately, his hope seems to rest on education and in the policies he outlined in an earlier book, "New Hopes for a Changing World". Here he gives us little clue as to how hope is to be substituted for fear and the co-operation secured on which world order and security can ultimately be based.

The Earl of Dundee, replying for the Government on the debate on February 11, affirmed that the right solution was disarmament by agreement, and collective security under a world system which commands the confidence and assent of all nations ; but he did not suggest that this could be achieved other than by patience and perseverance. He did not believe that it is possible to establish a system of world society in which conventional wars are still allowed but nuclear wars are excluded, and agreed with Lord Russell both that all future wars would be nuclear and that the Russian phobia about inspection is the real obstacle. He pointed out that Lord Russell had not really indicated what different method and new approach should be adopted, but in stressing the importance of a continued attempt to break down the cultural and intellectual barriers of the Iron Curtain and to establish real freedom of intercourse between the leaders of education, industry and science, between ordinary travellers and tourists, as well as the abolition of censorship, Lord Dundee went far towards accepting all that was constructive in Lord Russell's argument.

For the rest, the debate brought a further plea from Lord Boyd-Orr for world co-operation in applying the new powers of modern science to constructive purposes in the creation of a world free from war, hunger and preventable disease ; but Lord Adrian, who also supported Lord Simon's motion, merely emphasized the danger of allowing a nuclear war to start and the importance of preventing an increase in the number of Powers capable of starting such a war, without himself indicating any constructive steps to that end. Eventually, Mr. Selwyn Lloyd, Secretary of State for Foreign Affairs, in reply to questions in the House of Commons on April 15, said that the Government had proposed to the resumed Geneva Conference on nuclear tests that, if the Soviet Union could not agree to the steps required to make a comprehensive ban possible, attempts should be made to reach such a ban by stages.

The first stage would consist of a ban on tests from the Earth's surface up to 50 kilometres and under-water tests. Agreement on controls for this purpose seemed to be feasible, since on-site inspection would not be necessary. Efforts to work out the technical problems in detecting tests underground and at very high altitudes would continue without interruption, and as soon as satisfactory control provisions covering these points had been agreed and incorporated in the treaty tests in these environments would also be forbidden. Mr. Lloyd repeated that the Government would much prefer a comprehensive agreement but would accept the discontinuance of atmospheric tests as a first step and agree to negotiate further on the stopping of underground and stratospheric tests. (This has, of course, since been rejected.) Unlimited inspection had never been urged, but he thought that any control system is impossible if there is to be a Soviet veto on whether a complaint should be made and whether any alleged complaint should be inspected.

Lord Boyd-Orr's ideas concerning the importance of changing from the age-long use of war as the ultimate instrument of diplomacy to a new era of world peace, in which differences between nations will be settled by reason and goodwill, were more fully outlined in the presidential address he delivered to the Assembly of Corresponding Societies on August 28, 1958, at the Glasgow meeting of the British Association. Lord Boyd-Orr referred there to the economic and social problems which the great increase in the capacity for production of the modern world has created for the fully industrialized as well as for the underdeveloped countries ; but it was with the educational issues that his address was mainly concerned, particularly the education of the general public. He went so far as to suggest that what is needed to-day is a world-wide association for the retardation of science and for the preservation and increase of what culture we have available for dealing with the forces released by science.

In thus referring to the potential cultural value of the Assembly of Corresponding Societies, Lord Boyd-Orr was clearly referring to knowledge, wisdom and goodwill. It is obvious that we have still far to go before the Iron Curtain is no longer a barrier even in such fields ; but all measures to encourage cultural, educational and scientific exchange between the U.S.S.R. and the West could work to that end, and if the education of the public on the advancement of science and its impact on society become, as he suggests, the main function of the British Association, that Association might make an important contribution to world understanding. Meanwhile, an article by Prof. P. M. S. Blackett in *The Advancement of Science* (No. 60, March 1959) shows that the Association as a whole is making good progress in its new activities in presenting science to the public.

The Vienna Declaration of September 19, 1958, already noted, concluded by affirming the responsibility of scientists in all countries to contribute to the education of the peoples by spreading among them a wide understanding of the dangers and potentialities offered by the unprecedented growth of sciences. The Pugwash scientists appealed to their colleagues everywhere to contribute to this effort, both through enlightenment of the adult populations and through education of the coming generations. Both Lord Boyd-Orr's address and Prof. Blackett's article show that in Britain the British Association is already addressing itself to both aspects of the problem; but if scientists possess the special competence and responsibility attributed to them in the Vienna Declaration, these efforts will also require sustained support and constructive thought by professional associations of all kinds.

CORRESPONDENCE OF SIR JOSEPH BANKS

The Banks Letters

A Calendar of the Manuscript Correspondence of Sir Joseph Banks preserved in the British Museum, the British Museum (Natural History) and other collections in Great Britain. Edited by Warren R. Dawson. Pp. xlii + 965. (London: British Museum (Natural History), 1958.) £12 12s.

DURING the long reign of George III (1760–1820), and especially in the latter part, Sir Joseph Banks (1743–1820) was outstanding as the leader of scientific thought and development in Great Britain, above all in the realm of natural history in the widest sense. His great range of interests, his energy, his wealth, and his long term as president of the Royal Society, from 1778 until his death, enabled him to keep in close touch with the many and varied scientific activities of the period. Much has been written about Sir Joseph Banks but no full account of his voluminous correspondence and papers had been published, or even prepared, when they were largely dispersed, in part overseas, by sales in 1884 and 1886. The present volume is described as a Calendar and is concerned only with letters (originals or accepted *bona fide* copies) now in Britain. The extensive collections in other countries, especially in Australia, and the numerous reports, memoranda, or dissertations, mostly in his own handwriting, are not included. The letters listed with entries are now in the possession of many institutions and private persons, but the main collections are in the Department of Manuscripts of the British Museum, the Department of Botany of the British Museum (Natural History), and the Royal Botanic Gardens, Kew.

The Calendar as prepared and edited is arranged alphabetically on the basis of the names of the persons by whom or to whom the letters were written, and the letters are in order of date under the personal names, except for undated letters. For every letter there is given a concise epitome of its contents. So far as they have been traced, the dates of birth and death of the correspondents and an indication of their identity are given. Some idea of the magnitude of Banks's correspondence is given by the fact that the present Calendar contains entries of rather more than 7,000 letters and by the estimate that had the correspondence been intact the total would probably have been in the region of 50,000 or more. One has to remember that handwriting alone was involved, for in those days there were no typewriters or other modern devices for recording material not immediately to be published.

The work of reading and preparing explicit, if brief, entries of the contents of more than 7,000 letters must have been very considerable. The entries are well prepared and throw a great deal of light not only on the numerous and varied interests of Sir Joseph Banks and on the history of science in mid-Hanoverian times, but also on the conditions of life in Britain and other countries at this period. The basic alphabetical arrangement makes it easy to consult the entries and an excellent index enables the reader to make quick reference to subject contents.

In a short notice of a work of this nature and size it is impossible to do more than give general impressions of the range and value of the contents. As a source-book or a guide to sources for many purposes it will have considerable value. The historian of science, or of almost any branch of science, will frequently have to consult it, but many entries record matters outside the field of science. Indeed, it is the great range of Banks's interests and involvements which strikes one most in perusing the pages of this book. As Sir Gavin de Beer says in the preface he has written for the volume, "There is scarcely an aspect of British public life in the reign of George III that is not represented at first hand in the Correspondence of Sir Joseph Banks". He was certainly a remarkable man, and a great many institutions and individuals benefited from his advice and his often very concrete help. The British Museum, the Royal Botanic Gardens, Kew, and the Royal Society owe him a great debt, while many of the entries record thanks for kindnesses to individual correspondents.

It is appropriate that the present volume should be published by the Trustees of the British Museum. Not only did Banks contribute so much to the collections, particularly to those now at South Kensington, and a considerable part of the correspondence recorded in the body of the book is the property of the Museum, but also the work was originally initiated by the editor and the late Mr. John Ardagh, who was then in charge of the Library in the Department of Botany where the valuable Dawson Turner copies of so much of Banks's correspondence are available for reference. The editor and the Trustees of the British Museum are to be thanked for a production worthy both of the subject and of the institution.

W. B. TURRILL

AN INDIAN HISTORY OF SCIENCE

Bijnaner Itihas (A History of Science)

Vol. 2. By Sri Samarendranath Sen. In Bengali. Pp. xvi + 430 + 18 plates. (Calcutta: Indian Association for the Cultivation of Science, 1958.) Rs. 12.

THE first volume of this work (reviewed in *Nature*, 178, 1367; 1956) covered the period of ancient science up to the Roman empire; the second carries the story forward to the Renaissance and the birth of modern science. It amply fulfils the expectations aroused by its predecessor, indeed it surpasses them. The contents are divided into four parts. In the first part the author reviews the condition of scientific knowledge in medieval India. He discusses the contacts between Persia and the Mediterranean on one hand and China on the other, and carefully evaluates them. The most striking Indian contribution was in the field of mathematics and Mr. Sen summarizes the work of Varāhamihira, the sixth century polymath whom he calls the "Indian Pliny", of the great Āryabhat who—at the opening of the same century—calculated the correct value of π, of Brahmagupta, and of Bhāskara, the twelfth-century genius who explored the calculus. He further discusses the origins of the decimal system and the zero, and avoids the often exaggerated claims for their Indian antiquity. The Indian contributions, mainly by mathematicians, to astronomy are also worthy of remark, and Āryabhat even anticipated Copernicus. However, this field remained infertile largely because it was so much concerned with prognostication. Finally Indian contributions to medicine, chemistry, metallurgy and atomic theory are discussed.

The second part of the book deals with Arab science. Here too the material is presented in a sympathetic and balanced way. The great debt to Greek science is acknowledged as is the less-important Indian influence, and the achievements of al-Khwarizmi, al-Battani, al-Biruni and many others are outlined. A chapter is devoted to the Arab contributions to chemistry, particularly to Jabir, al-Razi and their followers; while in the field of medicine the name of ibn-Sina (Avicenna) stands forth.

With the third part of the book the scene is shifted to Europe and the background to the Renaissance. First, the survival of learning in the monasteries, the impact of the Carolingian renaissance, the effects of the Crusades and the influence of Arab science are considered; next the peculiar importance of the universities and their constitution are discussed. In this setting Christian and Greek learning mingle in Grosseteste and produce a Roger Bacon. The philosophy of Aquinas is outlined and leads up to a brief mention of the nominalists. It is indeed a joy to read in Bengali the translation of Occam's mighty razor. The section ends with a survey of knowledge in the thirteenth and fourteenth centuries.

The last part of the volume deals with the birth of modern science in the fifteenth century. First the author traces the technical discoveries which revolutionized life and thought: the magnifying glass, the clock, the compass, printing, and gunpowder. He then gives a full account of the work of Leonardo da Vinci. There follows a detailed history of the astronomical discoveries of Copernicus, Tycho Brahe, Kepler and Galileo. Next the great advances in anatomical knowledge are described, from Vesalius and Fabricius to Harvey. In chemistry, the work of Agricola is stressed and its practical importance is recognized. This second volume of the history of science ends with a short epitome of the seventeenth century as exemplified by Bacon, Descartes and Galileo.

It is indeed a pleasure to find in an Indian language so balanced and objective an account of this vast subject. This book carries with it something of the spirit which ennobles the writings of Sarton or Singer, and Mr. Sen is to be congratulated upon a remarkable achievement. As in the first volume the production is excellent, the illustrations are well chosen, numerous and well reproduced. It is impossible to overemphasize the importance of the history of science for education in India, and with the development of the regional languages the need for an adequate text-book is obvious. It is to be earnestly hoped that the Indian Academy for the Cultivation of Science may now take up the task of translating "Bijnaner Itihas" into the national language, Hindi, and the other regional languages, and that the Government of India may provide further support and encouragement for the task. We look forward to the publication of the third volume.

F. R. ALLCHIN

HUMAN DIVERSITY

Variation and Heredity

By Dr. H. Kalmus. (Survey of Human Biology.) Pp. xi+227+6 plates. (London: Routledge and Kegan Paul, Ltd., 1957.) 28s. net.

ASPECTS of human genetics, particularly the problem of assessing the changes in frequency of hereditary defects that may result from present or anticipated increases in the radioactivity of our environment, have been much in the public eye of recent years. Treatment in some sections of the Press, both in Britain and elsewhere, has often been emotional and invariably more imaginative than accurate. Even the controversies of the geneticists themselves have at times engendered more heat than light. Dr. H. Kalmus is therefore to be congratulated on the authorship of an objective and detached account of the factors, environmental as well as genetic, which contribute to human variability.

The book is the third volume of the "Survey of Human Biology" to appear. According to the publishers, the series is intended to serve three classes of reader, the inquiring layman, the student, and the specialist looking for information in fields other than his own. A clear and straightforward presentation is therefore required; also the avoidance of complexities and the limitation of technical jargon to a minimum. In these respects the author has succeeded admirably. Although the use of many technical terms is inescapable, the reader in return is entitled to have them clearly defined. Here Dr. Kalmus has been rather less successful. Definitions of a kind there are, but they by no means always appear at the first use of a term and the index is not always a reliable guide. This being so the usefulness of the book to its intended readers would have been increased considerably by the inclusion of a glossary. A comprehensive and up-to-date bibliography provides a partial compensation and is a valuable feature of the work.

The book is in no sense another elementary human genetics text, although genetics necessarily figures very prominently. The subject-matter is treated throughout from the point of view of its medical and social importance. Fourteen chapters of exposition are followed by three in which the wider implications for human affairs are discussed. The complex interaction of genetic and environmental factors is stressed and the absurdity of the supposed (by some) antithesis between 'genetically determined' and 'environmentally determined' characters is exposed. To those who have hitherto been unaware of this fallacy the reading of Dr. Kalmus's book should prove a salutary exercise.

There are a few minor errors and inconsistencies and one which may be more serious. On p. 139 it is stated that the genetic hazards of irradiation can be reduced by (among other methods) "... taking X-ray photographs instead of looking at the fluorescent screen, by which means irradiation with only two Röntgens can produce the same diagnosis as direct fluoroscopy requiring seventy-six Röntgens". Some readers are likely to take these figures to be gonad doses and since they have been told two pages previously that "... even such very low dosages as 0·3 to 0·1 Röntgen units per week or less ... constitute a potential threat to their [radiation workers'] progeny" they may well feel alarm. The actual dose which reaches the gonads will, of course, be greatly influenced by the part of the body under examination.

It is possible that doses of the magnitude mentioned may formerly have been delivered to the skin in some instances, but in contemporary practice (according to information given in a recent joint report of the International Committees on Radiological Protection and on Radiological Units and Measurement) gonad doses in even the most severe fluoroscopic examinations are likely to be at least an order of magnitude lower. This one slip apart, the book answers its purpose excellently and can be recommended to all who wish to have a readable and reliable statement of the present stage in the development of the study of human diversity. C. E. Ford

PHYSICAL AND CHEMICAL EXPLORATION OF THE CELL

General Cytochemical Methods, Vol. I

Edited by Prof. J. F. Danielli. Pp. xi + 471. (New York: Academic Press, Inc., 1958.) 12.80 dollars.

THE extraordinary growth in the number of 'annual reviews' or 'recent advances' series poses serious problems for contributors and editors. It is often very valuable for a research worker to review his own field, but once he has become established he may find himself the victim of an insidious process. It is flattering to be invited to contribute reviews and chapters and to take part in symposia; but there is a danger that many active minds are being diverted from research to writing. In some fields the number of reviews almost approaches the number of original papers. The relentless growth of such 'series' is partly to blame. Probably at no other time in the history of science have such a large proportion of reviews been written, and editors must be responsible for the careful selection of subjects and authors so as to avoid overlapping and repetition. The literature on cytological methods is already covered by reviews such as "Progress in Biophysics", "Advances in Medical Physics", and "International Reviews of Cytology," and collaborative works such as "Analytical Cytology", edited by Mellors, and "Physical Techniques in Biological Research", edited by Oster and Pollister.

It is a serious criticism of this new book that five of the nine subjects have already been dealt with (in some cases several times, and even by the same authors) in at least one of the publications mentioned above. Indeed the weight of cellular structures by X-rays (Engstrom and Lindstrom) and ultra-violet microspectrophotometry (Walker) have been the subjects of so many reviews that there is little new to offer. Both articles could have been held over for a year or two. The topics of Feulgen microspectrophotometry (Leuchtenberger), autoradiography (Pelc) and fluorescent antibody methods (Coons) have also been extensively reviewed elsewhere. It must be admitted that all these articles are well written and valuable in themselves, but it is rapidly becoming impossible for anyone to keep up with even the review literature.

The remaining four articles cover less familiar ground. Davies gives the fullest account (100 pages) of interference microscopy yet published. This is an admirable article and one wishes that every potential buyer of an interference microscope could be made to produce evidence that he has read and digested its contents. The exhaustive article (nearly 60 pages) by Bennett and Watts on the demonstration of sulphydryl groups by mercaptide coupling is perhaps less fortunate. One may admire the extraordinary thoroughness of the authors but it is surprising that the second longest article in the book was devoted to a method with (at present) such limited application. By contrast, the article by Holt on indigogenic staining methods for esterases is terse and severely practical. Finally, Danielli himself contributes a short article on the calcium phosphate precipitation method for alkaline phosphatase.

Having approached this book with a critical attitude, one wonders why, despite its imperfections, the general effect is a feeling of satisfaction. The answer is that not only is each of its articles authoritative and informative, but also the work as a whole preserves an integrity that is lacking in some other review journals. The articles are linked by a common theme and purpose and anyone concerned with cytochemistry can be certain that the majority of them will be of interest and value to him. Once this series is firmly established, it is to be hoped that reviews in this field will cease to be dispersed over a wide range of periodicals, thus making the task of the cytologist easier. Even though Prof. Danielli may not have got off to a perfect start, one feels that he is likely to make a very strong finish. R. Barer

PALÆOPEDOLOGY

Soils for the Archæologist

By Dr. I. W. Cornwall. Pp. 230. (London: Phoenix House, Ltd., 1958.) 50s. net.

MANY pedologists, like the reviewer, have no doubt been consulted from time to time by archæologists about problems that have arisen in the course of their excavations. That adequate help has not always been forthcoming is in the main due to lack of understanding between the two disciplines, and it is Dr. I. W. Cornwall's aim to reduce this to a minimum. The book is primarily directed at his archæological colleagues, but pedologists could read with advantage Part I of the book and the last chapter, both of which are devoted to a discussion of archæological deposits, but also containing useful information on loess, cave earths and peat. The core of the book is an account of soil types and some methods for their examination, and it is here that the pedologist will find most to argue about. The systematic discussion of the soils is based on Kubiena's "The Soils of Europe", with little modification. While from the morphological point of view this is, in the main, satisfactory, the theories of the underlying processes contain much that is pure guesswork and very debatable. Although Kubiena's techniques are now widely used, his classification is not generally accepted and it would have been helpful to have mentioned soil groups recognized by other workers, even though an accepted synonymy is not yet established. This would show that what is commonly called a podzol or podzolic soil in the U.S.S.R. need by no means correspond to Kubiena's definition although it might fit one of his other groups. In this connexion a set of photomicrographs of the types of fabric should have been provided.

There is much use of the theory of peptization of iron oxide by silica for which there is no good evidence, although silica sol will peptize clays. In the British Isles (cf. p. 98), as elsewhere in the temperate zone, water-soluble silica can be extracted from soils, and is therefore presumably hydrated. The remarks about the colour changes of hydrous iron oxides on dehydration are open to question, for it is a fact that in many red soils goethite is the main identifiable form. Crystal growth is a more probable explanation of the colour changes. The iron oxides in a braunerde are said to be flocculated, and therefore immobile, so that concretions do not form (Kubiena, p. 234), but Dr. Cornwall allows them to be "typically seen in braunerde" among others. This may be true if one uses the more general expression 'brown earths'. Such concretions formed in the earlier history of the soil do not necessarily shrink and become deformed (p. 191) but may retain their shape and structure. Again, a braunerde does not necessarily become degraded to a podzol on increase in acidity; unless heath intervenes, a form of sol lessivé is a more likely result.

The author's descriptions of laboratory techniques are unorthodox but in general probably adequate. In mechanical analysis, however, it is better to use 'Calgon' systematically unless the coarser fractions are examined for aggregates of silt and clay. The removal of gypsum is readily effected by ammonium acetate. In the method for the determination of *p*H (p. 166) the proportion of soil to water is surely a misprint. Under iron, mention might have been made of a method for 'free' iron oxide, the determination of which is commonly more useful than total iron. It should also be pointed out that a sharp increase in total iron in the subsoil does not necessarily indicate podzolization, for this effect is shown by grey-brown podzolic soils (sols lessivés). The observed variation in *p*H with depth in this group of soils (also in some tropical soils), namely, a minimum value in the lower *B* horizon, suggests an alternative explanation of the results of the Mersea section (p. 207). The top of the decalcified layer could well be the surface of the buried layer rather than the point of minimum *p*H as seems to be assumed by Dr. Cornwall.

A pioneer effort like this book must inevitably have its defects, but the author has made a valiant attempt to provide a bridge between two disciplines that should lead to valuable results in the future. Alex Muir

SEMI-CONDUCTORS

Solid State Physical Electronics

By Prof. Aldert van der Ziel. Pp. x+604. (London: Macmillan and Co., Ltd., 1958.) 37*s*. 6*d*. net.

The expanding use of semi-conductor and dielectric devices during the past decade or so has been so rapid and widespread that there now exists in the design and applications of these devices what is virtually a new branch of electrical engineering. The development of these devices has been accompanied by the publication of a number of books written primarily to provide accounts either of the special circuit techniques involved in their use or of the relevant aspects of solid state physics. However, this book provides a new approach by aiming at giving an understanding of the *operation* of solid state devices. The book attempts to cover this whole field in a single volume designed to fill the need for a collected and concise account of the exploitation of the physics of the solid state over the whole of this rapidly expanding subject.

The first five chapters of the book deal briefly with the relevant basic physics required. Topics which are discussed include particle and wave aspects of light and matter, particle statistics, and the structure and band theory of solids. The next six chapters form a section dealing with the various mechanisms of electron emission from solids, and the design and characteristics of relevant devices such as thermionic vacuum tubes, photo-tubes, and secondary emission multipliers; approximately half this section is devoted to thermionic emission and its applications. The physical principles and operation of the more important semi-conductor devices are treated in the next six chapters. Metal to semi-conductor rectifiers and photo-effects in semi-conductors occupy one chapter each, but most of this section is concerned with a relatively extensive treatment of the junction diode and in particular the transistor and its equivalent circuits. Dielectric and magnetic materials and their applications are dealt with in the remaining six chapters. Topics discussed here include luminescence and the light amplifier, transducers, ferroelectricity and the dielectric amplifier, the solid state maser, and ferrite devices.

It is inevitable that, in covering so wide a subject in a single volume, some applications have to be omitted; for example, no mention is made of parametric amplification. The discussion of topics included is necessarily curtailed although each chapter is followed by a short list of references to original literature and additional texts for supplementary reading. Formulæ required are sometimes quoted without derivation, for example the equations for Fermi-levels in semi-conductors given on p. 90; and physical concepts are sometimes introduced without discussion of their background, for example the introduction of thermodynamic free energy on p. 511. However, since the emphasis of the book throughout is on providing an understanding of the operation of devices rather than on giving a detailed exposition of fundamental solid state physics or circuit engineering, this is not necessarily a disadvantage.

The book is well written and printed, and is easy to read although the large number of extensive footnotes employed does tend to break up the reading of the text. Unfortunately, the value of the book is reduced slightly by the presence in it of a number of minor errors such as observations in the text which disagree with the relevant diagram, for example the Fermi-level in Fig. 12.3*b* is raised and not lowered; numerical magnitudes given wrongly, for example the spontaneous polarization of barium titanate given on p. 526 should be about 0·26 C.m.^{2}; and misprints in the text such as the Fermi function on p. 51 and the thermoelectric power quoted for metals on p. 463. Most of these are trivial but do cause some confusion and irritation.

As is the growing practice in this field, the book utilizes the M.K.S. system of units, includes a useful short table of fundamental physical constants, and gives a number of representative problems, with answers, at the end of each chapter.

To the student of engineering or physics, this book provides a useful and comprehensive introduction to the many different ways in which solid state physics is at present being exploited; to the specialist worker in this field the book will serve as a reminder of the very wide ramifications and potentialities of his subject. Notwithstanding the various criticisms made here of this book, there is no doubt it is an important publication and can be recommended widely.

G. T. Wright

SURMISE AND FACT ON THE NATURE OF CANCER

By Dr. PEYTON ROUS, For.Mem.R.S.
Rockefeller Institute for Medical Research, New York

THE hypothesis according to which tumours are due to mutations of somatic cells was first brought forward by Boveri in 1902 and has been debated ever since. It was presented anew last July at one of the few plenary sessions of the International Cancer Congress in London. The state of mind of many research workers when this Congress ended has been reported as follows[1]: "Some hoped that cancer can be eradicated without an understanding of its very nature; others felt that we must understand better the enigma of the cancer cell and even of life itself. If the somatic mutation theory of cancer is right, then development of cancer is an inherent property of life, and cancer research is but in its lusty infancy".

Obviously a great deal depends on whether the hypothesis is right. For what men think determines not only what they do but also what they do not; and numerous workers on cancer are now content to think that it results from somatic mutations. Hence they see no reason to seek in other directions to learn its nature. The factual basis for this state of affairs will be considered here, as also the share of the hypothesis in the advancement of knowledge. Important reasons exist for doing this—the biological importance of the cancer problem, its urgency for man, and the present state of mind of many scientists now investigating it, as just mentioned.

During the first years after Boveri proposed the mutation hypothesis[2] the changes of normal cells resulting in tumour cells were held to occur "of themselves", like germinal mutations: and since the changes appeared to be abrupt and discontinuous, as in the case of these latter, and also heritable, being passed on at every cell-division, the assumption seemed warranted that they might be due to genuine mutations—but of somatic cells dying with the organism. Now we know that neoplastic changes are not spontaneous, but are induced by extraneous agents or conditions, in the generality of instances, and almost certainly in them all. It has become rule of thumb, on finding a tumour, to look for the agent bringing it on. Hundreds of agents which do this—the so-called carcinogens—are now known, and new ones are continually being discovered. Most of them act slowly, some effecting neoplastic change only after many years; but their influence is cumulative, no matter how long the interval between exposures to them, and eventually they render some cells neoplastic. They are of the most heterogeneous character, ranging all the way from radiant energy and highly various substances, to viruses and animal and vegetable parasites. Yet, except for the viruses, they have little determining influence on the character of the growths they induce. In doing so they play upon the neoplastic potentialities a tissue possesses, and these differ not only with the kind of cell implicated, and the species of animal, but even with its breed. Some carcinogens reach deep into the body, and others are made there.

This new knowledge has large practical bearings as witness the demonstrated relationship between cigarette smoking and lung cancer. As yet, however, it has thrown no piercing light on the nature of neoplastic change. The great majority of the carcinogens are merely provocative: they convert normal cells into tumour cells but have no further essential role and are degraded or left behind as the changed cells multiply. Their relation to the neoplastic state may be likened to that of ignition to combustion: a fire can be kindled in any one of numerous ways but, with this done, its decisive share in events is ended. The analogy can be pushed further: flames differ according to their ingredients and tumours differ according to the type of cell involved.

The realization that tumours are induced phenomena made necessary an adjustment of the mutation hypothesis. According to present thought, the carcinogens induce mutational changes and these result in the growths—upon which they may have some selective effect, a corollary presumption. In this form the hypothesis becomes most attractive, providing as it does a blanket explanation for almost the whole diverse world of the neoplasms. Yet not for quite all of them. How does it account for the small but gradually enlarging group of tumours that are produced by viruses, which, incidentally, determine their character, and are made up of cells in which these viruses multiply and from which they can be recovered in a condition to produce more tumours of the same sort? A first inclination was to exclude the growths from consideration as not genuine neoplasms: and this has recently been attempted anew, despite proof that they measure up in all ways to the classical definition of what tumours are, save in that their cause has been found. To reconcile their existence with the mutation hypothesis some workers now consider the causative viruses to be 'transmissible mutagens' affecting the genes of somatic cells.

Needless to say, somatic mutations, recognized as such by the geneticists, do occur. They are frequent in plants and now and again are found in the lower animals but are exceedingly rare in the higher. They are regularly cited by such investigators as hold that tumours are due to somatic mutations, and with reason, since without them this assumption would have no directly factual basis. The earlier they occur in the development of an organism the greater is their share in it, through multiplication of the affected cells. Occasionally one of them finds expression in the vertical half of a plant, not infrequently in a branch or leaf or flower, and often in the mere segment of a petal, when that petal had already begun to form before the mutation occurred. The changed branch or leaf or segment still retains the form and functions of such, but differs from the normal in colour or texture or both. But it is significant that none of the plant tumours thus far studied has been found in association with these mutations.

In the higher animals somatic mutations are so seldom come upon as to gain individual report. They have been noted very occasionally in pigeons, guinea pigs, sheep, rabbits, and rats. Half the body of a pigeon may be covered with black feathers instead of the normal grey of the opposite half; or a patch of skin on a guinea pig or rabbit may carry fur having a colour different from that to be expected by its inheritance; or a patch of wool on a sheep may be notably shallow as compared with its fleece elsewhere. These anomalies are not passed on to the next generation. The cutaneous patches have been aptly termed 'mosaics'; for they are surface phenomena, the skin with the abnormal fur or fleece remaining level, and its cells retaining their normal place and activities, not extending downward or laterally at the expense of the adjacent tissues, much less proliferating into a mass as tumour cells do. Few, if any, somatic mutations seem ever to have been observed in mice, which is the more surprising because, throughout many years, thousands of these animals have been under close scrutiny in the Jackson Laboratory at Bar Harbor, Maine, a laboratory largely given over to the experimental study of mouse genetics, much of it by inbreeding. This latter has resulted in numerous homogeneous strains of mice useful for scientific purposes, some prone to develop tumours of one organ or another in a high percentage of instances; yet no breed has yet been reported having any discernible tendency to somatic mutations of recognized type. Only plant instances find mention in the numerous papers from the Jackson Laboratory, wherein the somatic mutation hypothesis has been advocated.

Still more remarkable is the fact that no valid 'mosaics' have been reported for human skin, so accessible as this is to constant inspection and so intimately inspected. It may well be that they occur; but if so they have been ascribed to some cause other than somatic mutations. The only phenomenon indicative of them in man is the occurrence of paired eyes of markedly different colour, one blue and one brown, for example, when they should resemble each other by inheritance. The deeper human organs have been searched microscopically for more than a century, yet no abnormalities have been reported by pathologists that can be referred with any assurance to somatic mutations.

In 1932, J. S. Haldane[3], after studying the somatic mutations then available, wrote that "the known alterations in [cell] character which can be referred to chromosomal changes are of a much less fundamental kind than would be required to explain malignancy in tumours. . . . Even when a chromosomal mutation is inconsistent with the ultimate survival of the developing organism [its] growth is still co-ordinated". This latter fact is well exemplified in the ill-matched eyes already mentioned, as also in 'sheep mosaics', which, alone among those of animals, have been examined with the microscope. This has shown that the skin involved in the mosaics has the normal aspect, except that its hair follicles are smaller than usual and form smaller hairs. The cutaneous cells give no sign of increased ability to proliferate, much less to do so independently of the organism. Here lies the crucial difference between neoplastic cells and those that have undergone somatic mutations of the kinds thus far recognized.

One can readily understand why somatic cells that have undergone authentic mutations such as those thus far reported should rarely manifest themselves. Their lack of any increased ability to proliferate must result in their virtual imprisonment within the normal tissue context, unless indeed they have mutated early in the development of the organism to which they belong. Actually, in the adult creature, many tumour cells are unable to assert themselves even when possessed of considerable ability to grow. But if they are provided with space, as by cutting away the tissue next to them, or if the tissue in which they lie is stimulated chemically, such hidden cells may promptly form tumours[4], their proliferation far exceeding that of the adjacent, and competing, normal cells of the sort from which they have derived. Not so with cells that have undergone authentic somatic mutations of the kind above described: their growth fails to exceed that of their normal fellows. Only when they have mutated so early in the life of the embryo as to share to a recognizable extent in its formation can they be expected to multiply sufficiently to gain attention.

If one could only bring chemical carcinogens to bear on mammalian embryos at an early stage, one might learn whether these agents are mutagenic as well; but nearly all of them fail to get through the placenta. Radiant energy does reach into the uterus, and malformations due to its action on embryos have been described, but no somatic mutations. Fortunately, one chemical carcinogen, ethyl carbamate (urethane), which induces lung tumours in mice, and is frequently mentioned by the somatic mutationists because it causes germinal mutations in *Drosophila*, does pass the placental barrier[5]; and it acts with such swiftness on the embryos of mice of some breeds, when these are injected with it while pregnant, that adenomatous tumours can be perceived in their pulmonary tissue within three days after birth[6]. The lungs are almost as well suited as skin to the disclosure of somatic mutations, because the least morphological change in their delicate, orderly, alveolar web can be discerned: yet even when urethane is brought to bear on the embryos almost as soon as their pulmonary tissue first begins to form, and daily thereafter, through injection into their mothers, no signs of somatic mutations have been found in serial sections of their lungs, obtained at intervals from their birth to maturity, but only the well-known adenomas—growths capable of forming a succession of tumours when serially transplanted.

On turning now to the tumours themselves that are ascribed to somatic mutations, one learns much that is pertinent. The assumption is often tacitly made that the changes in aspect and behaviour which occur when normal cells become tumour cells are consequent merely on their increased proliferation. But only exceptionally, and in cells of a few sorts, do neoplastic changes seem to result only in an increased capacity to grow. In such cases the increase is slight (for example, some fatty tumours of man, certain liver tumours of mice). Of course, when neoplastic cells multiply rapidly they have less time to differentiate and hence tend to diverge more from the normal; but those of many cancers exhibit great distortions of form and function, irrespective of whether their proliferation be fast or slow. The cells of such tumours are almost grotesque in aspect and worse in behaviour, invading, destroying, scattering to other organs, and multiplying so rapidly that they outstrip the ability of the body to supply them with blood vessels and in consequence die in hordes. Cancerous cells much less changed than these still differ strikingly from normal cells. One is reminded again of Haldane's dictum that "the known alterations in [cell] character which can be referred to chromosomal changes are of a much less fundamental kind than would be required to explain malignancy in tumours".

The cells of the most fatal human cancers are far removed from the normal in character, and almost no growths fill the gap between, much less a graded series of them, such as one might expect were they the outcome of random somatic mutations, all tumours in this series, or rank, consisting of neoplastic cells of the same derivation but diverging more and more from the norm in the direction of the malignant state. Cancers of the human lung are exceedingly common whereas pulmonary tumours of any other sort are rare; gastric cancers outnumber more than 20 to 1 the benign adenomas derived from cells of the same sort; and cancers of the epithelium lining the body of the uterus and its cervix are frequent, whereas adenomas are uncommon. In none of these instances can the rarity of the benign tumours be ascribed to any lack of free space in which they may assert themselves, nor are stimulating influences wanting to them. Furthermore the benign tumours are in a much 'healthier' state than the malignant, and hence their scarcity cannot be ascribed to any inability of their cells to survive. Wide differences, crucial to the patient, separate growths of the two kinds. To all practical intents and purposes the cancers are discontinuous, episodic phenomena; yet they are so repetitive that the clinical pathologist can predict the course of this one or that out of his past experience with others of the same sort.

The absence of any ordered gradation of tumours, their discontinuous incidence, can be seen in animals as well. By inbreeding litter mates throughout many generations, strains of mice have been obtained which carry a liability to tumours of one sort or another, as already mentioned. Those of some breeds have mammary growths, others lung tumours or liver tumours or bone tumours, and yet others leukæmia. The growths of the mamma and lung have been most closely studied. In the lung they are always benign adenomas of distinctive morphology, whereas in the breast they are equally characteristic, epithelial cancers. Though they are episodic phenomena, several often arise in a single animal.

Nearly all ageing female mice of some breeds die of mammary tumours, and though less frequent in mongrel mice they are the most common of all growths. Hence they were the main material studied during the first ten years of experimental cancer research. They could only be propagated by transplanting their living cells, and the failure of all efforts to extract a causative agent from them led to the conclusion fifty years ago that they were consequent on innate, cellular changes. They became indeed the very citadel of the belief (revived anew during the recent International Cancer Congress) that the riddle of cancer will be solved only with that of life itself; and, like the other tumours occurring 'spontaneously' in genetically homogeneous mice, they were long held to be due to an inherited tendency. So matters stood until 1934 when a Dutch worker and a group at the Bar Harbor Laboratory discovered independently that this tendency is passed on through the mother. A little later, one of the Bar Harbor group demonstrated that their cause is a virus passed to the young in their mother's milk, yet causing no harm until after they mature, when cancers develop in consequence of its action. Do viruses account for the other tumours occurring in inbred mice? The organs of all are identical in form and function; yet growths of this sort or that arise in this or that breed, whereas not in others. What can be the *tertium quid*? The fact that a carcinogen, 20-methylcholanthrene, hastens the occurrence and increases the frequency of the cancers determined by the milk virus, and also that of the lung adenomas and leukæmias already mentioned, possesses a suggestive significance in this connexion. Indeed, recently a leukæmia of the mouse has yielded a virus that quickly produces the disease in others[7].

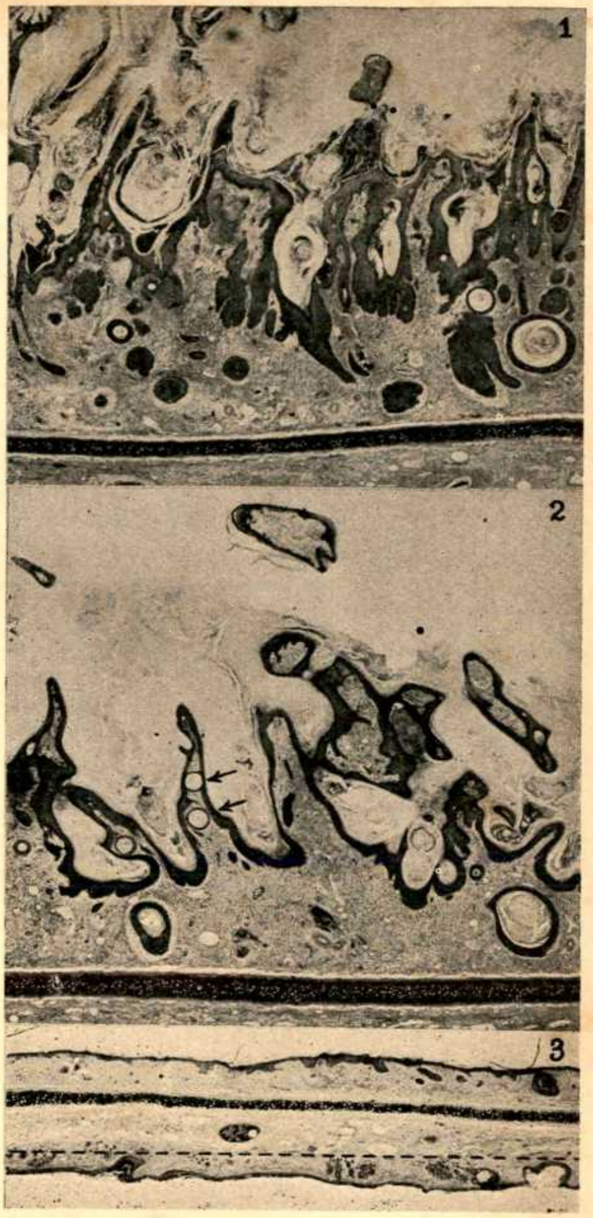
Many experiments have been made of late to learn whether carcinogenic agents cause somatic mutations in the lower forms of life[8]; and the advantage of using micro-organisms has been pointed out, these undergoing no separation into somatic and germ cells. Tests of them, as also of *Drosophila*, have shown beyond doubt that some carcinogens can induce permanent biochemical changes in cells exposed to them. Two distinguished investigators[9] sum up the results of their recent work on the mutagenic effects of carcinogenic hydrocarbons upon *Neurospora*, and "other similar findings", with the statement that they are "at least not inconsistent with the somatic mutation hypothesis". The evidence as a whole makes plain though that some carcinogens induce somatic mutations whereas others do not, that some mutagenic agents fail to be carcinogenic, and that many substances closely related chemically to agents of both sorts do neither[10]. Persistent search has been made, ever since Boveri's time, for chromosomal alterations which might prove characteristic of the neoplastic state—all to no purpose.

Cancer cells often undergo further discontinuous changes, and these have been many times noted in cultures of the normal, somatic cells of mammals; but since normal cells can proliferate endlessly *in vitro* the only way to tell whether they have become neoplastic is to return them to creatures of the kind from which they derived. This has been done, and mouse fibroblasts long exposed in culture to methylcholanthrene have given rise to sarcomas. But the control cultures became sarcomatous also. This would be astonishing were it not known that some substances deemed innocuous, lard, for example, will induce sarcomas after injection amid the fibroblasts of intact mice or rats. The cultures maintained longest, and yielding most sarcomas, though of late with no carcinogen purposely added, had been grown for several years on sheets of 'Cellophane', a material recently shown to induce sarcomatous changes when embedded amid the connective tissue of rats and mice[11]. Other foreign materials that might be carcinogenic have been present in the fluids nourishing the cultures—horse serum, extracts of chick or bovine embryos, and human amniotic fluid or serum from the blood of the umbilical cord. In one set of exquisite experiments, fibroblasts from the heart of a rat were cultivated in a mixture of cord serum and chick embryo extract, and throughout 2½ years the air about them was repeatedly replaced by nitrogen for the maximal period that the cells would survive. On return to rats at the end of this time the cells gave rise to sarcomas whereas those of the control cultures, maintained without anaerobiosis, did not[12]. One is reminded of the sarcomas arising now and again in human arms which have for years been poorly oxygenated because greatly swollen as a result of operative interference with lymph drainage[13]. It would appear that carcinogenic conditions—conditions that is to say which bring on the neoplastic state—have determined both the human tumours and the malignant changes occurring in cultured rat fibroblasts.

The term 'mutations', instead of the objective term 'variants', is often applied nowadays to the discontinuous changes occurring in somatic cells grown in tissue cultures. But how many of them deserve the name ? The neoplastic viruses bring about wholly analogous changes in the cells of intact animals, and they would surely be ascribed to somatic mutations by the advocates of this hypothesis had not their causes been found. One is reminded in this relation of the numerous 'orphan' viruses that have turned up of late in tissue cultures, strays from unknown sources, as also of the fact that Newcastle virus can persist in tissue cultures without giving any cellular sign of itself, yet be roused to pathogenicity by experimental procedures[14]. Scientists have only begun to realize that microbiological entities, distinct from the apparatus of cells, may accompany these, and do no one yet knows what. The discovery of a 'Kappa factor' in the cytoplasm of *Paramecia* provides an instance in point. One should not presume on this realization, but it cannot be dismissed. While adventuring into the infinitely great we are experiencing what the exceedingly small can do to us.

When Boveri first outlined his idea that tumours are consequent on somatic mutations[2] he pointed out that it was not incompatible with the assumption that their primary cause is parasitic in nature. Indeed, he inclined to this possibility, having noted that physical and chemical insults can cause multipolar mitoses to occur in sea urchin embryos. In this connexion an extraordinary, recent revelation should now be mentioned, namely, that bacterial viruses sometimes transfer genetic material from one kind of bacterium to another, the result being an enduring transformation of the latter[15]. Several workers have suggested that the neoplastic viruses do something similar to the normal cells of animal tissues, inducing somatic mutations that convert them into tumour cells. The question might be asked whether this reconciling assumption (of transmissible mutagens) may not apply to viruses producing growths which fall somewhat short of the standard for typical neoplasms—to the Shope fibroma virus, for example, which causes rabbit growths that resemble tumours in all important ways except that after some weeks they regress : and if to the Shope fibroma virus, surely to the virus of rabbit myxomatosis into which it can be readily transformed. Myxomatosis is a fatal inflammatory process, though entailing some cell proliferation ; and certain strains of vaccinia also cause cells to multiply though they die soon after. Now one comes to the frankly necrotizing viruses. What of them ? Is one to suppose that they kill cells rapidly by transferring genetic material to nuclei, or are they directly lethal ?

These justified questions carry no implication that viruses are harmless to the genetic apparatus of cells. They may well play havoc with it. But to assume this in the case of neoplastic cells is less than neces-



Figs. 1–3. Effects of scharlach *R* in olive oil when placed beneath rabbit epidermis. A tourniquet was applied to the ear of an anæsthetized rabbit, stopping all circulation to its distal third, and then olive oil saturated with scharlach *R* was injected into a marginal vein of this third, under such pressure as to rupture many capillaries. As a result, numerous tiny droplets of oil escaped into the subepidermal tissue

Fig. 1. Inner side of an ear 23 days after injection. The epithelium has undergone an enormous proliferation and has extended down toward the oil droplets. Both in aspect and behaviour it appears cancerous

Fig. 2. Later stage, with the dye almost gone from the oil. Epithelial invasion has ceased, and many of the droplets are surrounded by a layer of what now looks like ordinary epidermis, and are in process of extrusion (arrows)

Fig. 3. Ear 69 days after injection. It has nearly returned to the normal. Numerous lacunæ where oil still persists can be seen on the outer (under) side of the ear ; but on its inner side, where the tissue was tightly bound to the cartilage, few are left

The portion of the ear shown in Figs. 1 and 2 lies above the broken transverse line in Fig. 3

(Eosin and methylene blue stains : all are at the same magnification) sary. In 1906, a German pathologist, seeking some substance that might be the cause of cancers, found that a dye, scharlach *R*, when dissolved in olive oil and injected beneath rabbit epidermis, would cause its cells to behave as if malignant[16]. This finding was soon confirmed by numerous workers: to all appearance an actively invasive, squamous-cell carcinoma is called forth by the dye (Figs. 1–3). But not for long: the epidermal cells revert to the normal as its influence wears off.

Here is no somatic mutation. The physical character and chemical activities of the neoplastic viruses, as such, may well be the cause for the neoplastic changes they produce, changes passed on from one cell to another because the viruses themselves multiply and are passed on.

At the time of writing, the somatic mutation hypothesis, after more than half a century, remains an analogy: "it is presumptive reasoning based on the assumption that if things have similar attributes they will have other similar attributes"[17]. No discoveries that tighten this analogy have been made. Of course, one can assume that tumours are due to somatic mutations of some qualitative type unrecognized as yet, thus piling surmise on surmise.

A hypothesis is best known by its fruits. What have been those of the somatic mutation hypothesis? It has resulted in no good thing as concerns the cancer problem, but in much that is bad. It has led within the year to an authoritative statement, in the lay Press, that since cancer is certainly due to somatic mutations, the possibility of having it is "inherent"; and that this being so, the most man can ever do is to palliate such malignant tumours as may have become disseminated in the body and to avoid new carcinogens as well as the old.

Here is fatalism to blast many a hope and effort. Fortunately, the public, now empowering large-scale attempts to cure cancer, are a hard-headed generation. They have learned the lesson of the antibiotics, substances that do deeds transcending all medical preconceptions.

Most serious of all the results of the somatic mutation hypothesis has been its effect on research workers. It acts as a tranquillizer on those who believe in it, and this at a time when every worker should feel goaded now and again by his ignorance of what cancer is.

THE CHAPELCROSS NUCLEAR POWER STATION

By J. C. C. STEWART

THE Chapelcross Works of the United Kingdom Atomic Energy Authority, which was opened on May 2, is situated about two miles to the east of Annan, Dumfriesshire, Scotland.

The Works consists of four gas-cooled graphite-moderated reactors, each of 180 MW. heat design output with electricity generating plant of 140 MW. electrical net design output, together with the associated ancillary equipment. The output will comprise irradiated uranium containing plutonium of military grade with electricity as a by-product.

Construction started at Chapelcross in 1955, and the first reactor was commissioned in February 1959. The existing programme calls for the station to be fully commissioned in March 1960.

Early in 1955 the decision was taken to increase the production of plutonium for military purposes. At the time the construction of Calder Hall was well under way. Investigation showed that the Calder site could only be doubled in size to give a four-reactor station. The increased production demands required a six-reactor programme over and above the two original Calder reactors. Accordingly, a site suitable for a four-reactor power station was sought in reasonable proximity to the Windscale plutonium factory to ease the transport problem associated with the irradiated material. The Chapelcross site, a former Royal Air Force airfield, was chosen in May 1955. Fuel supplies for the reactors come from the Springfield Works of the United Kingdom Atomic Energy Authority in Lancashire.

The major items of the Station are identical with those at the Calder Hall Works, the details and performance of which have been described elsewhere[1,2], but modifications based on experience at Calder Hall have been introduced where appropriate. There are, however, large differences in overall layout. As the Chapelcross construction plan called for a four-reactor station *ab initio*, the reactors were conveniently built in line, this arrangement allowing the use of a single large turbine house with four adjacent cooling towers. Geographical compactness is thus achieved compared with the protracted *A* and *B* station layout on Calder, a factor which should ease operating and maintenance problems. As the station is about 75 miles distant from the plutonium factory at Windscale, it has been necessary to provide a water-filled storage pond for irradiated uranium to provide flexibility in operation and to ease the transport problem.

A recent modification of design introduced on Chapelcross reactors Nos. 2, 3 and 4 concerns the introduction of removable graphite sleeves into all fuel channels, to provide a solution to the problems

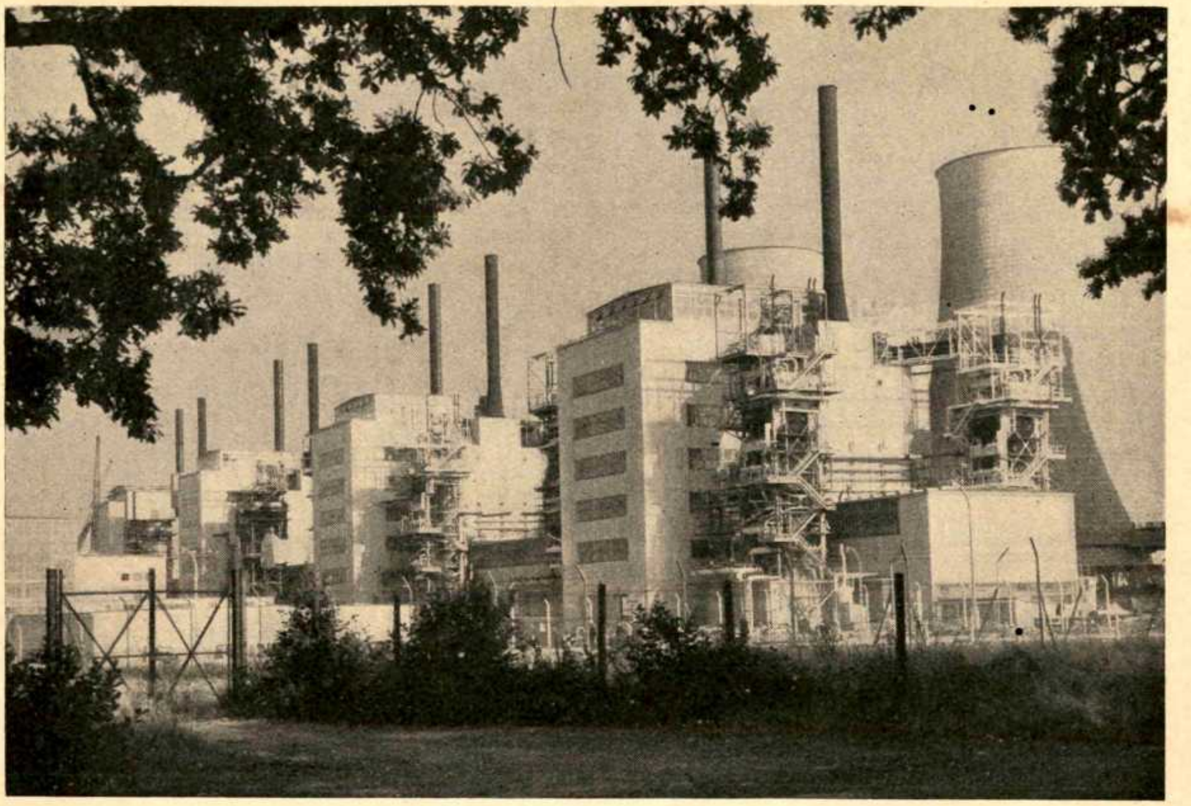

Fig. 1. Chapelcross Nuclear Power Station. Copyright reserved: U.K. Atomic Energy Authority, Risley

of stored energy associated with irradiation damage of the graphite moderator.

The results of this damage are usually described as Wigner effects after E. Wigner, who, in 1942, predicted that atoms in moderators would be displaced by fast neutrons. Those displacements could be permanent in the absence of annealing, with corresponding changes in physical properties. The present model assumes that a moving carbon atom which has suffered fast-neutron impact at first loses energy principally by electronic excitation. As its energy diminishes there is an increasing probability of an elastic collision with other carbon atoms and this creates a group of displaced carbon atoms situated at interstitial sites together with a corresponding set of vacant lattice sites. The physical results of these displacements appear as changes in thermal and electrical conductivity, elastic constants, thermal expansion, Hall effect, physical dimensions and heat of combustion. It is the two latter properties which largely affect reactor design and operation.

Changes in physical dimensions are catered for by utilizing the differing growth-rates along the various axes, by permitting adequate growth clearance where necessary and by allowing unrestrained growth in directions not associated with critical alignments.

Changes due to heat of combustion are due to the stored energy, inherent in the carbon atom displacement process, which may build up as irradiation proceeds.

In the event of graphite with a stored-energy content being heated sufficiently above the normal temperature at which irradiation occurs, release of the stored energy will be initiated. Moreover, after sufficiently long irradiation, it is possible to have a stored-energy content per unit mass greater than the specific heat of the graphite. With the appropriate combination of the above circumstances, a stored-energy release could be self-propagating and could lead to high graphite temperatures with consequent hazard to reactor operation.

Fortunately, the changes in physical properties are decreased as the irradiation temperature is raised, due to the increased mobility of the interstitial atoms, with increased probability of self-annealing. This factor has eased considerably the stored-energy problem at Chapelcross and Calder compared with the Windscale reactor, the respective gas inlet temperatures being 140° C. and 20° C. However, no further raising of inlet gas temperatures is possible with the existing reactors by virtue of temperature limits on the blow casings and inlet ducts. Accordingly, an alternative solution has been found in the provision of removable graphite sleeves in the channels, which are so designed that a small gap is left between them and the bulk of the graphite. This gap acts as a thermal barrier between the moderator and the coolant, and ensures that the temperature of the bulk graphite is raised above its normal value.

This solution has two variants in that different methods are possible for reactors which have operated and for reactors which are under construction. In the second case, it is possible to modify the core bricks prior to erection and to fit removable graphite sleeves without reducing channel diameters. This solution is being adopted for Chapelcross reactors Nos. 2, 3 and 4. No. 1 reactor will use the alternative method of sleeving, whereby 'Magnox' sleeves are lowered into unmodified channels, if this is necessary in the future. This latter operation reduces reactivity and channel flows, thus reducing power, and adds appreciably to the times during which a reactor is out of action. Hence the graphite sleeve solution has been adopted wherever possible.

The water-filled storage pond for irradiated uranium is a feature not provided at Calder Hall owing to its close proximity to the Windscale ponds. The addition of the pond makes Chapelcross more akin to the new nuclear power stations now under construction for the Central Electricity Generating Board and South of Scotland Electricity Board, these also having individual storage ponds. The pond at Chapelcross has sufficient capacity to hold a number of cartridges equivalent to about three reactor charges. Irradiated fuel will be taken to the pond using standard containers holding twenty-four cartridges, will be left to decay for some months and will then be transported by road to the plutonium-processing plant at Windscale.

The major functions of the pond are to ensure that transport delays do not affect the times during which a reactor is out of action, and to ease the transport problem so far as vehicles, containers and man-power are concerned.

The Chapelcross reactors, like those at Calder, can only be refuelled when they are shut down and when the coolant gas pressure is at near atmospheric. It has been found that the refuelling time virtually determines the time the reactor is out of action, any necessary maintenance can be effected simultaneously, and hence it is essential to keep refuelling time to a minimum to ensure maximum production. The pond assists in this by providing a storage point in the fuel cycle and thus allowing refuelling operations to be almost entirely independent of external transport arrangements.

The second advantage of the storage pond is that it permits utilization of the natural radioactive decay of the irradiated fuel elements. Any decay eases the shielding problems associated with any subsequent handling operations. After the delay period, it is estimated that it will be possible to transport from Chapelcross to Windscale six times as many cartridges per container as is possible for Calder to Windscale. The Chapelcross containers are about 50 per cent heavier, but there is nevertheless a gain factor of four in the number of cartridges per container, thus diminishing the requirement for containers, vehicles and man-power.

OBITUARIES

Sir Robert Muir, F.R.S.

Sir Robert Muir, emeritus professor of pathology in the University of Glasgow, died in his ninety-fifth year on March 30 at Edinburgh, where he had lived in retirement for some time. He was born at Balfron, Stirlingshire, on July 5, 1864, but soon afterwards his father, a clergyman, was called to Hawick, and he grew up there. He graduated in arts at Edinburgh in 1884, M.B., C.M. with first-class honours in 1888, and M.D. with honours and a gold medal in 1890. He entered the Pathology Department under Greenfield with a Vans Dunlop Scholarship, and there began his original investigations into the reactions of the leukocytes.

Muir's scientific contributions fell into four main divisions. First (1888–1902) there were his studies on leukocytosis, which established that the enormous increase in the number of neutrophil polymorphonuclear leukocytes found in certain infections resulted from proliferation and differentiation of the finely granular myelocytes of the bone marrow; the significance of the leukoblastic reaction was thus revealed. Secondly, studies on immunity (1903–12) were concerned chiefly with the properties of hæmolytic antisera. Results obtained by rigorous quantitative methods led to a brilliant analysis of the antibody–complement mechanism. *Inter alia,* it was shown that, whereas complement is firmly combined with the antigen, the immune-body remains dissociable. This is incompatible with a supposed 'amboceptor' constitution of the latter. The existence, also, in complement action of two distinct factors was clearly defined, namely (*a*) combining affinity for the sensitized antigen, and (*b*) toxic action. The chief results of Muir and his co-workers were published together as "Studies on Immunity" (London, 1909); they contributed largely to the foundation of immunology in Great Britain. Thirdly, work on hæmolysis *in vitro* led to investigations on the effects of hæmolytic sera *in vivo*; these enabled new observations to be made, on the storage and utilization of iron (with Shaw Dunn), and on the metabolism of the blood pigments (with J. W. McNee); thus they played a substantial part in the development of Aschoff's concept of the reticulo-endothelial system. Further work followed on the breakdown of hæmoglobin (with Janet Niven) and on the relation of hæmoglobin to the liver cells (with J. S. Young). Fourthly, Muir studied the evolution of cancer of the breast and the spread of cancer cells from the mammary ducts into the epidermis giving rise to Paget's disease of the nipple; his masterly account of these lesions is the most detailed and accurate that has so far been produced.

Muir was elected a Fellow of the Royal Society in 1911 and was awarded a Royal Medal in 1929 for his contributions to immunology. In 1936 he was the first recipient of the Lister Medal who was not himself a surgeon. Muir had an enormous influence on medical teaching both at home and abroad. The "Manual of Bacteriology", first published jointly with James Ritchie in 1897, quickly became the standard work and reached its eleventh edition. In 1924 he added the "Textbook of Pathology", of which the last edition from his own pen was the fifth (1941).

The secret of Muir's greatness in his subject and his profound influence is not easy to define: it appeared to reside essentially in two qualities. In research, he had remarkable judgment and an almost intuitive insight that enabled him to go directly to the heart of the problem. He also carried an aura of intense integrity, and in his presence insincerity and pretentiousness seemed to wither. He was called upon to serve on many committees, both administrative and scientific, and his advice was much sought by universities and Government departments.

To his staff and students Muir was to some extent an enigma. He evoked in them an outstanding affection and loyalty that was entirely uncourted, and in his professional life-time he was something of a legend, many apocryphal tales being told of him. Robert Muir was a highly cultured man, interested in art, literature and music, and he combined these with a keen delight in sport, especially golf and angling. He was knighted in 1934 and was the recipient of many honorary doctorates and fellowships.

D. F. Cappell

Sir Guy Marshall, K.C.M.G., F.R.S.

Sir Guy Anstruther Knox Marshall, director of the Imperial (now Commonwealth) Institute of Entomology during 1913–42, died in London on April 8 at the age of eighty-seven.

Marshall was born in India in 1871 and educated at Charterhouse. Having been unsuccessful in entering the Indian Civil Service, he joined a firm of mining engineers in Salisbury, Southern Rhodesia, in 1895. His intense interest in natural history and acute powers of observation had ample scope in Rhodesia and, in collaboration with the late Sir Edward Poulton, and inspired by him, he published a paper on his observations in the *Proceedings of the Royal Entomological Society of London* of 1902. In 1906 he returned to Great Britain determined to devote his life to entomology, and in 1909 he was appointed scientific secretary to the Entomological Research Committee (Tropical Africa) by the Secretary of State for the Colonies. Almost immediately he started the publication of the now well-known *Bulletin of Entomological Research*, and his energy and enthusiasm were such that in 1913 an Imperial Bureau of Entomology was established. This new organization embraced, and was supported by, all the countries of the British Empire; it was to be a centre of information with two main functions, to issue a monthly periodical giving abstracts of all current literature dealing with noxious insects and to identify injurious insects sent in by workers overseas. The *Review of Applied Entomology*, the abstract journal, first appeared in January 1913 and is now in its forty-seventh volume. At the beginning of 1914 Dr. Sheffield Neave, who had represented the Committee in East Africa since its inception, was appointed assistant director and eventually followed him as director of the Institute in 1942.

The great value of the service that Marshall was building up was quickly recognized by Governments overseas, and first the mycologists of the Commonwealth, and later research workers in other branches, pressed for a similar service. All these services, covering practically all branches of agricultural science, are now grouped together in the organization known as the Commonwealth Agricultural Bureaux.

As adviser on entomological matters to the Colonial Office, he played a very important part between the two World Wars in guiding the development of entomological work in the Colonies and in advising on specific problems. He had a particular interest in tsetse fly research, stemming from his early experience of this pest in Southern Africa. Throughout his long life he never ceased to stimulate, inspire and help entomologists from the Commonwealth, in their work of controlling insect pests. He was a firm believer in commercial companies and insecticide manufacturers employing their own entomologists, and his influence in this direction did much to raise the standard of insecticide products and the service rendered to the public.

Apart from his other activities, Marshall was a leading specialist on the Curculionidae for more than half a century. From 1902 until his death, he published two hundred works on the systematics of weevils, including the descriptions of 2,269 new species of weevils. His major works were "A Monograph of the Genus *Hipporrhinus*" (1904), a volume of "The Fauna of British India" (1916), "Insects of Samoa" (1931), "Entomological Results of the Swedish Expedition 1914 to Burma and British India" (1948) and "The Otiorrhynchine Curculionidae of the tribe Celeuthetini" (1956). He identified the large quantities of weevil material received at the Institute for determination with great promptitude, and he continued to do so after his retirement in 1942, working constantly at the British Museum until a very few weeks before his death.

Marshall received many honours: hon. D.Sc. (Oxon.) 1916; C.M.G. 1920; F.R.S. 1923; knighthood 1930; K.C.M.G. in 1942. He was a corresponding member of the American Academy of Sciences, Philadelphia, honorary member of the Royal Society of New Zealand, of the National Institute of Science, India, of the Entomological Society of Belgium, of the Entomological Society of Russia and an honorary fellow of the Royal Entomological Society of London.

He married in 1933 and is survived by his wife and two stepsons. He will be sadly missed by a host of friends in Great Britain and abroad.

W. J. Hall

Dr. Lynde P. Wheeler

Dr. Lynde P. Wheeler died on February 1, at Roanoke, Virginia, U.S.A., at the age of eighty-four, after a long and active career in physics and radio communication. For many years he was associated with Yale University; he graduated in 1895 and became associate professor of physics during the period 1923–26. In 1918, he also spent some months at the National Bureau of Standards, Washington. On leaving Yale, Dr. Wheeler joined the U.S. Naval Research Laboratory near Washington and, during his ten years service there, he was associated with the application of radio and allied techniques to naval problems. His long experience in radio matters was then made available to the Federal Communications Commission, where he became chief of the Technical Information Section for the period 1936–46. On retirement from the Commission, he became staff-consultant to Pickard and Burns Inc., of Needham, Massachusetts.

Dr. Wheeler was actively associated for many years with the Institute of Radio Engineers (New York), and particularly with its Washington section. He was elected a Fellow of the Institute in 1928, and served as president in 1943.

NEWS and VIEWS

Mathematics at Newcastle upon Tyne:

Prof. W. W. Rogosinski, F.R.S.

PROF. W. W. ROGOSINSKI retires from the chair of pure mathematics at King's College, Newcastle upon Tyne, in the University of Durham in September. He was appointed to the chair at King's College in 1948 after a distinguished career in Germany, Cambridge, Aberdeen and Newcastle, having established an international reputation for his work on Fourier series and functions of a complex variable. During his tenure of the chair he has worked mainly on extremum problems in function spaces. He has written a series of papers concerned with finding minimal representations and maximal points of linear functionals, with applications to extremum problems, systems of linear equations with infinitely many unknowns, generalized moment problems, and other problems of classical analysis. In 1954 he was elected to fellowship of the Royal Society. The Department of Mathematics, and all its activities, have expanded rapidly since 1948, and Prof. Rogosinski has given enthusiastic support and encouragement to all its members. He is held in high esteem and with great affection by his colleagues throughout the College, and he will be greatly missed. His mathematical zeal, however, will be sustained by his appointment to a chair in Denmark.

Prof. F. F. Bonsall

ON the retirement of Prof. W. W. Rogosinski the chair of pure mathematics at King's College, Newcastle upon Tyne, University of Durham, has been filled by the appointment of Mr. F. F. Bonsall. Mr. Bonsall studied at Oxford with an interval for war service. After holding a temporary lectureship in the University of Edinburgh, he was appointed a lecturer in pure mathematics at King's College and became a reader in 1956. His research work has been mainly concerned with partially ordered vector spaces, particularly spectral properties of linear operators mapping the positive cone into itself.

Royal Society Research Appointments

THE Council of the Royal Society has made the following appointments in original scientific research. Royal Society Research Fellowships (Mr. and Mrs. John Jaffé Donation) have been awarded to: Dr. G. Hoyle, of the Department of Zoology, University of Glasgow, to work on excitation/contraction coupling in muscle and nervous mechanism in behaviour of insects, from October 1, 1959, at the Department of Zoology and Institute of Physiology, University of Glasgow; and to Dr. J. Owen, of the Clarendon Laboratory, Oxford, to work on exchange interactions in magnetic systems, from October 1, 1959, at the Clarendon Laboratory, Oxford. Royal Society Research Studentships (Mr. and Mrs. John Jaffé Donation) have been awarded to: Mr. K. L. Manchester, of the Department of Biochemistry, University of Cambridge, to work on the mechanism of the regulation by hormones of protein synthesis, from October 1, 1959, at the Department of Biochemistry, University of Cambridge; and to Dr. M. J. Whelan, of the Crystallographic Laboratory, Cavendish Laboratory, Cambridge, to carry out investigations of metals by transmission electron microscopy, from October 1, 1959, at the Department of Physics, Cavendish Laboratory, Cambridge. John Murray Travelling Studentships in oceanography and limnology for 1959 have been awarded to: Mr. A. D. Ansell, of the Marine Station, Millport, Isle of Cumbrae, to work on problems of the laboratory rearing of bivalve larvæ at the U.S. Fish and Wildlife Laboratory, Milford, Conn.; and to Mr. G. Evans, of the Imperial College of Science and Technology, University of London, to work on marine sediments at sea but based on the Scripps Institute of Oceanography, La Jolla, California.

Rockefeller Institute, New York: Fellowships for Foreign Students

DR. DETLEV W. BRONK, president of the Rockefeller Institute, has announced that the Institute has received a bequest of approximately one million dollars from the estate of the late Sophie D. Fricke, of New York City, who died on March 1, 1958. Miss Fricke was born in Jersey City, but lived most of her life in New York where she was confidential secretary to many prominent business executives. Through wise investment of her personal savings, she created the fortune which she left for the furtherance of human welfare through support of science. The Trustees of the Institute, which has recently been transformed into a postgraduate university, have authorized use of the income from the Fricke fund for the triple purposes of fostering international understanding, training scientists of exceptional promise, and supporting significant research. To this end, four distinguished research fellowships will be awarded each year to young scientists in Britain, France, Denmark and Sweden for study and investigation at the Institute. The Fellows will be appointed by the Royal Society of London, the Paris Academy of Sciences, the Royal Danish Academy of Sciences and Letters and the Swedish Royal Academy of Sciences. Each Fellow will carry the designation of his sponsoring society. For example, the Fellow from Britain will be known as the Sophie Fricke Royal Society Research Fellow in the Rockefeller Institute. Each of the Sophie Fricke Fellows will receive an annual stipend of 10,000 dollars with an additional 1,000 dollars for travel in the United States.

"The objective of these fellowships," said Dr. Bronk, "is to foster closer relations between American scientists and their colleagues from abroad. It is our intent that the Fellows be young men and women of exceptional promise who are likely to be leaders in science in their respective countries and will, therefore, ultimately be appointed to distinguished posts in their native lands. Having spent one or two years in the United States under exceptionally favourable circumstances before assuming posts of responsibility at home, these men and women will be in an unusually favourable position to develop the associations with American scientists begun while at the Rockefeller Institute. All the facilities of the Institute and the advice and guidance of the Institute's distinguished faculty will be available to the Fellows; they will be free to work on problems of their own choosing or they may collaborate with one or more members of the Institute Faculty."

Sir K. S. Krishnan, F.R.S.

On December 3, 1958, Sir K. S. Krishnan celebrated his sixtieth birthday, and to commemorate this event the contents of the December issue of the *Journal of Scientific and Industrial Research* included two special features. The first is a reprint of the article describing Prof. Krishnan's distinguished scientific career which Prof. K. R. Ramanathan contributed to the Souvenir Volume published by Prof. Krishnan's Sixtieth Birthday Celebrations Committee, New Delhi. The second consists of a 110-page supplement containing reports of the work carried out under the auspices of the Indian National Committee for the International Geophysical Year, 1957–58, of which Prof. Krishnan was the chairman and active director. A brief foreword to the supplement is followed by two short articles entitled "Sir K. S. Krishnan and the International Geophysical Year" and "Space Exploration—An Achievement of the I.G.Y.", by Profs. Sydney Chapman and L. V. Berkner, respectively, and sections devoted to meteorology, geomagnetism, ionosphere, solar activity, cosmic rays, latitudes and longitudes, glaciology, oceanography, rockets and satellites, and seismology, containing twenty-four reports in all. India took part in every one of the fourteen divisions of the international programme and maintained, in addition to a large network of meteorological stations, about sixty other observation stations distributed all over the country. India's geographical position and the vast area of the country render its particular contributions to the International Geophysical Year programme of special significance, and the detailed results given in the reports are a valuable addition to geophysical data and a stimulus to the conquest of space.

The Microbiological Research Establishment

In reply to a question regarding the work of the Microbiological Research Establishment in the House of Commons on May 4, the Minister of Supply, Mr. A. Jones, said that the work of the Establishment is of much wider interest than its aspects relating to the defence programme and involves fundamental studies in microbiology which have applications in preventive medicine. Mr. Jones instanced the development and production of a completely safe vaccine against anthrax and the production of raw material for Asian influenza virus vaccine used in the 1957–58 epidemic. During 1958 more than 80 articles were published by members of the staff in medical and scientific periodicals, and biological materials were regularly provided for use in microbiological departments engaged in medical research at universities and other institutions. In reply to a further question, the Minister said that it is the Establishment's function to study the problem of biological warfare and much progress has been made. It is not now thought that botulinus toxin would be an effective agent, and efficient protective measures have also been developed. Our ability to assess and encounter the threat has increased with the growth of our knowledge of the subject from research, but much still remains to be done.

Mathematics in American Secondary Schools

"An Emerging Programme of Secondary School Mathematics", the Inglis Lecture for 1958 (pp. viii + 44. Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1959. 7*s.* 6*d.* net), is an account, given by Prof. Max Beberman, of a diagnostic experiment in teaching method which has been in operation since 1952 under the auspices of the University of Illinois. The investigation is designed to establish whether mathematicians can formulate a course of instruction for pupils, and a programme of training for teachers, so that the subject may have a greater appeal to the average child. The lecture postulates two fundamental principles for a course now being applied to the last four years (age range about 13–17) in twelve American high schools. The first principle, the need for precision in language, is exemplified here by the ability to appreciate the difference between the figure '3', the name 'three' which we apply to this figure, and the 'number' three which is the *class* of sets of three things. The second is the necessity for discovery as an aid in understanding the nature of mathematics; examples relate to directed numbers, the solution of equations and inequations ($|2x + 1| < 7$), the manipulation of algebraic expressions and the 'ordered pair' approach to analytical geometry. In this account there is insufficient detail to give the reader a convincing understanding of the effectiveness of this actual programme. Enough is said, however, to establish beyond doubt that only by such experiments in training and teaching under pilot conditions can the content of the syllabus in school mathematics be settled with any real certainty.

Language, Literature and Science

Prof. A. Norman Jeffares's inaugural lecture in the chair of English at the University of Leeds has been published by the University (pp. i + 24. Leeds: The University Press, 1959. 2*s.* 6*d.*). It is a matter for satisfaction and congratulation that Prof. Jeffares has made a plea for the presentation of the best scientific writing as literature. On one hand, the scientist should consider the clearest and most cogent method of presenting his knowledge to those who are not workers in scientific fields; and on the other, the arts student must endeavour to understand the significance of the aims and methods of, and the changes in the world wrought by, science. "Humanism must include science: a refusal on the part of the man trained in arts to launch himself into the sea of scientific thought is as dangerous for us as any obfuscation of that thought on the part of a scientist untrained in the technique of using his own language —'Science is or ought to be poetry and poetry is knowledge, and the humanity of the future will not divide life but unite it'. But the humanism of the future depends upon our reading of the literature of both humanism and science, upon our listening to those who conserve, add to or modify both these traditions of humanism and science, and upon our own writing and speaking good English, the existence of which is the common bond between humanism and science."

International Federation of Societies of Cosmetic Chemists

A meeting took place in the rooms of the Chemical Society, Burlington House, Piccadilly, London, on April 15, when representatives of eight countries met to discuss the formation of an International Federation of Societies of Cosmetic Chemists. This Federation would link together the various autonomous national societies into an international body, capable of acting in such fields as international standards, establishment of the professional status of the cosmetic scientist, publication of bulletins, abstracts and reviews on cosmetic science, to name only a few. The countries represented on this occasion were: Belgium, Denmark, France, Germany, Great Britain, Norway, Sweden and the United States. Agreement was reached on a provisional constitution. The delegates are now returning to report to their national societies, and as soon as possible a second council meeting will be held to draw up a final constitution. A provisional secretariat has been established in London (2 Lovers Walk, London, N.3), but the final headquarters have yet to be agreed.

Technical Assistance under the Baghdad Pact

In a written answer in the House of Commons on April 9, Mr. R. Allen, Joint Under-Secretary of State for Foreign Affairs, stated that at the sixth session of the Baghdad Pact Economic Committee in January 1959, the Government announced its intention to make available £850,000 per annum for technical assistance under the Baghdad Pact. This will be used for the supply of equipment and technical experts to Turkey, Iran and Pakistan and to provide training in the United Kingdom for nationals of those countries. In addition, the Government had contributed the equipment for the Nuclear Training Centre in Baghdad as well as some of the staff and running costs. Negotiations between the Pact Organization and the Iraqi authorities for the disposal of this equipment had not yet been completed.

Scottish Technical Education Consultative Council

In a written answer in the House of Commons on May 1 the Secretary of State for Scotland, Mr. J. Mackay, announced that the new consultative body on vocational further education would be known as the Scottish Technical Education Consultative Council; its terms of reference would be "to secure the widest possible measure of consultation on vocational further education in Scotland between employers, employees and those responsible for its provision, and to advise on, and generally to promote, the development of such education". Its chairman will be Mr. E. P. Hudson and its vice-chairman, Sir David Anderson.

Government Chemist's Department

It was announced by Mr. J. E. S. Simon, Financial Secretary to the Treasury, in a written answer in the House of Commons on May 4, that the Government agrees with the Linstead Committee that the arrangement whereby the Chancellor of the Exchequer is responsible for the Government Chemist's Department is inappropriate in the present organization of Government scientific work. As from July 1 next, Ministerial responsibility for the Department will be transferred to the Lord President of the Council, and the Department will be placed in the charge of the Council for Scientific and Industrial Research.

Building Research

In answer to a question in the House of Commons on May 5, the Minister of Works, Mr. H. Molson, said that the Government has for some time recognized that there is room for improvement in the co-ordination of building research, and it has therefore been decided to place all such research under the Department of Scientific and Industrial Research. He is not therefore re-appointing his Advisory Council on Building Research and Development, and in its place there would be a Standing Conference on Building Research under the ægis of the Lord President of the Council. The dissemination of technical information will remain his responsibility and he is discussing with the industry the many problems involved in providing rapid facilities for this purpose.

Journal of Biochemical and Microbiological Technology and Engineering

It is generally recognized that chemistry imposes certain special conditions on the technologists and engineers who work in chemical industry. Biology, too, possesses its own characteristics which must be understood by people who are proposing to use living cells for practical purposes in biological industry. It is with this in mind that three editors, two from the University of London and one from Columbia University, New York, assisted by an advisory board of sixteen drawn from Australia, India, Ireland, Italy, The Netherlands, Sweden, Switzerland, the United Kingdom and the United States, have brought out this new journal. The first number (*Journal of Biochemical and Microbiological Technology and Engineering*, 1, No. 1; February 1959. Pp. 127. Published quarterly: subscription, covering one volume annually, £5 15*s*., including postage; outside the United Kingdom, 15.50 dollars. New York and London: Interscience Publishers, Inc., 1959) contains nine papers which nicely illustrate the kind of topics with which the publication is intended to deal. For example, an American contribution describes the separation of proteins by means of foam; N. W. Pirie reviews the principles employed in different types of presses, filters and centrifuges by which fluids may be separated from fibrous pulps on a large scale; and the British Flour-Millers Research Association presents a paper on the use of air classification as a means of varying the protein content of flour. Besides these, there are reports on equipment for the culture of algae and of micro-organisms of diverse kinds for various purposes, on the destruction of moulds by irradiation, on the evaluation of microbiological nutrients and on means for the removal of algae from drinking water. Pure and applied science must always be inextricably mixed. Neither physicists nor chemists could achieve their modern triumphs without their technologies. The present journal can usefully inform biologists about theirs.

Locusts and Atmospheric Turbulence

In a paper entitled "Flying Locusts and Atmospheric Turbulence" (*Quart. J. Roy. Meteor. Soc.*, 84, 334; 1958), Dr. R. C. Rainey describes the relation between the structures of the lower atmosphere and of locust swarms over eastern Africa. It is found that, in a convectively unstable atmosphere of very high lapse-rate of temperature, the locusts are carried high into the air in the convection currents. They are spread out over a considerable depth rather like a cumulus cloud so that there is a nearly clear space for some distance above the ground, while the top of the swarm approaches the limit of the region of high lapse-rate at 1–2 km. above the surface. During stable (isothermal) conditions, on the other hand, the swarm forms a thin layer at a height of a few tens of metres above the ground. In such conditions, locusts frequently settle on the ground, and take off again as the swarm progresses. The locust swarm is not, however, merely carried along by the air and dispersed by turbulence as though it were a cloud of dust particles. Evidence is presented to show that, even in highly convective air, the swarms persist as swarms. The facts presented in the paper are of importance in selecting suitable occasions for spraying locust swarms with insecticide and also, to an extent restricted by the little-understood coherency property of a swarm, in the study of convection currents. The paper contains two photographs vividly illustrating the difference between locust swarms in convective and stable atmospheres.

New Guinea

A RECENT issue of the *Australian Museum Magazine* is devoted almost entirely to New Guinea (12, No. 12). The physical geography is described by D. F. McMichael and the geology by G. A. U. Stanley. J. S. Womersley discusses the vegetation of the island, while other contributors provide details about the mammals, birds, fishes and insects. Until the early 1930's it was thought that the central region of New Guinea was uninhabited and uninhabitable. Since that time it has become known that about 600,000 people live in the Australian territories alone. These, and others of the many different types of natives, are described by A. P. Elkin. This issue is also of interest for its reference to the discovery of a rare animal in Australia, the potoroo (*Potorous tridactylus*). This animal, which is related to the rat-kangaroos, is now rare in New South Wales, not having been recorded in the State since 1913. It is still common in Tasmania. The specimen obtained by the Museum was killed by a dog near Gosford, New South Wales.

"Chlorothiazid in Diabetes Insipidus"

Drs. John D. Crawford and G. C. Kennedy write: "We have recently reported that chlorothiazide has an antidiuretic action in experimental and clinical diabetes insipidus, both of the pituitary deficiency and nephrogenic varieties (*Nature*, March 28, p. 891). It has been brought to our notice that Drs. H. Reerink, Eveline E. Brongers and H. Schouten reported on the use of chlorothiazide in the treatment of three cases of nephrogenic diabetes insipidus before the Dutch Organization for Paediatrics at Eindhoven on June 15, 1958. Their rationale was 'to impede the (renal) tubular reabsorption of Na and Cl in order to induce the excretion of these ions into the urine for the purpose of regulating the level of these electrolytes in the blood'. We would like to acknowledge their priority in the successful use of chlorothiazide for amelioration of symptoms in nephrogenic diabetes insipidus".

Announcements

THE Challenger Society is prepared to make small grants for research in marine biology or oceanography at a recognized laboratory during the year June 1959–60. Applications, accompanied by details of the proposed research, should reach the Hon. Secretary, Challenger Society, National Institute of Oceanography, Wormley, near Godalming, Surrey, not later than May 30.

FOR a number of years the directors of the Associations of Chemical Manufacturers in western Europe have found it useful to meet from time to time to examine together questions of common interest. In view of the number and scope of the problems facing the chemical industries of these countries at the present time, the Austrian, Belgian, British, Dutch, French, German, Italian, Swedish and Swiss Chemical Manufacturers Associations have decided to improve their collaboration and contacts by setting up a Centre Européen des Federations de l'Industrie Chimique, the secretarial services of which are to be entrusted to the Swiss Association in Zurich.

A MEETING of the members of the Co-operative Research Project on Trace Elements of the United Nations Food and Agriculture Organization, organized by An Foras Talúntais (The Agricultural Institute, 33 Merrion Road, Dublin), will be held in Dublin during May 20–23. The results of the recent survey of trace-element research problems made by Prof. T. Wallace of Long Ashton Research Station, Bristol, co-ordinator of the project, will be discussed at the meeting. Other subjects for discussion will be the evaluation of trace-element deficiencies in Europe; the status of research on trace elements; methods of trace-element analysis and methods of strengthening research and collaboration on trace elements.

THE Food and Agriculture Organization of the United Nations will offer ten or twelve André Mayer Fellowships in 1959. These awards will be made in the following two groups: (*A*) *Research*. For unusually promising persons with research experience behind them who would offer a guarantee to carry out independent research work. (*B*) *Research training*. For younger and promising individuals who have demonstrated an inclination towards, and an aptitude for, research work. The subjects presented must be related to the Organization's activities. Further information can be obtained from the Secretariat of the Food and Agriculture Organization, National Committee for the United Kingdom, Ministry of Agriculture, Fisheries and Food, Whitehall Place (East Block), London, S.W.1.

THE Summer Meeting of the Photoelectric Spectrometry Group will be held in Nottingham on June 12. Further information can be obtained from K. A. Macdonald, Unicam Instruments, Ltd., Arbury Works, Cambridge.

THE seventeenth International Congress of Pure and Applied Chemistry will be held in Munich during August 30–September 6. Further information can be obtained from Dr. R. Morf, c/o Sandoz, S.A., Basle 13, Switzerland.

THE Scientific and Technical Group of the Royal Photographic Society is holding a symposium on Photography in the International Geophysical Year on June 6 in the Adam House Theatre, Chambers Street, Edinburgh 1. Further information can be obtained from Mr. D. Brownbill, Technical Service Department, Ilford, Ltd., Ilford, Essex.

THE Eastern New York Chapter of the American Society for Metals will sponsor a conference on the Fracture of Engineering Materials during August 23–25 at the Rensselaer Polytechnic Institute, Troy, New York. Further information can be obtained from Richard W. Hardt, General Engineering Laboratory, General Electric Company, 1 River Road, Schenectady, N.Y.

THE summer courses of the Italian Physical Society's International School of Physics will be held in the Villa Monastero, Varenna, during June 15–September 15. Courses will be held on thermodynamics of irreversible processes; weak interactions; solar radio-astronomy; physics of plasma; experiments and techniques. Further information can be obtained from the Società Italiana di Fisica, Via Saldini, 50, Milano.

THE FONTÉCHEVADE SKULLS AND THE ORIGIN OF *HOMO SAPIENS*

THE long-awaited full report on the human remains from the Fontéchevade Cave (Charente) in south-western France, where in August 1947 the fragmentary skulls of two individuals associated with a Tayacian industry were discovered by Mlle G. Henri-Martin, has now been published*. The palæontological and chemical evidence of their age, taken in conjunction with that of archæology and stratigraphy, points to an early part of the Riss–Würm interglacial—some authorities favour the Riss glaciation itself—or a time preceding the advent of the Mousterian culture associated with Neanderthal man. Fontéchevade I consists of a small piece of the glabellar region of the frontal bone, and Fontéchevade II, which has been affected by burning, of almost the whole left parietal, the upper half of the right parietal, and the upper portion of the frontal.

Prof. H.-V. Vallois concludes that Fontéchevade I belonged to an adult subject of probably female sex. It is slightly thicker than the corresponding region in modern European frontals and does not show any marked development of the glabella, its most characteristic feature for so ancient a specimen being the complete absence of a supra-orbital torus. His study of Fontéchevade II is lengthy and thorough, involving comparisons of separate characters with those of Lower and Middle Palæolithic fossil skulls from Europe and western Asia. In this the defective state of the specimen necessitated the making of assumptions in the reconstruction of certain missing regions. According to Prof. Vallois, its owner was probably male and 50–60 years old at the time of death. The cranial capacity he determines from one of the Lee–Pearson reconstruction formulæ based on calvarial length, breadth, and auricular height (measured from the biporial axis to the apex and not, as erroneously stated in Rudolf Martin's "Lehrbuch der Anthropologie", to the bregma), less 50 cm.^{3} as an allowance for exceptional thickness of bone, to be 1,470 cm.^{3}. A preferable formula would seem to be the corresponding one of Hooke[1], used by Morant to estimate the capacity of the Swanscombe skull[2], which, with the same deduction as before, yields an even higher figure of about 1,550 cm.^{3} for Fontéchevade II. However, the arbitrary nature of such estimates from incomplete material must be stressed. The dimensions of the skull are in any event considerable. As seen from above, the vault is pentagonal, the greatest breadth is situated at a low level, and the biasterionic diameter has a high value. The frontal bone, like that of Fontéchevade I, apparently lacks a torus and has no post-orbital constriction. There is an absence of parietal foramina, which it shares with the majority of the more ancient representatives of fossil man.

The fourth chapter of Prof. Vallois's monograph is an attempt to assess the taxonomic position of the Fontéchevade Tayacians, whom he now compares *en bloc* first with three different 'Neanderthal' groups, namely, the 'classic' Neanderthals of the last or Würm glaciation in Europe, the pre-Neanderthals of the same continent, including the Ehringsdorf and the two Saccopastore skulls, all from the Riss–Würm interglacial, and the Steinheim skull, probably of Rissian age, and the Palestinian Neanderthaloids, dating from the Riss–Würm or the Würm I–II interstadial; then with European fossil *Homo sapiens*; and finally with the Swanscombe skull from the Mindel–Riss. So far as the classic Neanderthals are concerned, Prof. Vallois points out numerous distinctions between these and the Fontéchevade skulls, a categorical one being the form of the forehead and in particular the absence of a supra-orbital torus in the Tayacians, a feature also separating them from the remaining two 'Neanderthal' groups treated by him. He replies to critics who, broadly speaking, are unconvinced that the Fontéchevade fragments can be distinguished in any definitive way from the pre-Neanderthals of Europe, and stresses the close resemblance that exists between Fontéchevade II and the Swanscombe skull.

Prof. Vallois then devotes a substantial portion of his text to the 'Presapiens' concept, that is to say, the reasons in favour of the existence of a line of fossil men who, while more ancient than the classic Neanderthals, nevertheless differ from them and from the pre-Neanderthals in the complete absence of a supra-orbital torus and display in this and other characters an approach to *Homo sapiens*. He discusses in turn the development of this concept and the claims for various finds to be included in the 'Presapiens' category. Briefly, only three individuals qualify, the two from Fontéchevade and the Swanscombe skull, of which the frontal bone is missing. He next considers the argument that the Swanscombe skull, if its frontal were present, could have been furnished with a torus as developed as that of the almost contemporary Steinheim skull, a suggestion first made by Morant, who pointed out the similarity in bone thickness and in the conformation of the occiput between Swanscombe and Steinheim. A provisional diagnosis of 'Presapiens', based on the traits of the Fontéchevade and Swanscombe skulls, is followed by the statement that it represents a primitive form of *Homo sapiens*, from which 'Presapiens' was probably not specifically distinct and of which it ought logically to be considered as an initial stage.

In his fifth chapter Prof. Vallois reviews the theories of the origin of *Homo sapiens*, which he classes under three main heads: (1) direct derivation from classic Neanderthal man, (2) derivation from pre-Neanderthals, and (3) derivation from a source independent of either, that of 'Presapiens'. The essentials of the case for each are set forth with the lucidity and encyclopædic knowledge of which the author is so remarkable an exponent. Naturally enough, the solution that he himself favours is the third one, that which envisages a separation of the lines leading respectively to *Homo sapiens* and to the classic Neanderthals in the Lower Pleistocene and perhaps no earlier than its post-Villafranchian phase.

Presented though they are with the skill and authority that Prof. Vallois commands, the arguments in support of the 'Presapiens' thesis, as expounded by him, have had a mixed reception among students of human palæontology. Thus the veteran Prof. Sergio Sergi, in a paper devoted to the Swanscombe and Fontéchevade remains[3], emphasizes the uncertainty of an adequate morphological diagnosis from them owing to their incompleteness. While acknowledging that they possess some traits in common with *Homo sapiens* such as the absence of a supra-orbital torus in Fontéchevade and certain metrical features in Swanscombe, he believes that their platycephaly, great biasterionic diameters, and posterior expansion of the base of the parietals are structurally archaic features the importance of which has been underestimated. In other words, it is not possible to recognize different pre-Neanderthal and 'Presapiens' groups much before the Würm. For Sir Wilfrid Le Gros Clark the morphological traits of Swanscombe and Fontéchevade as well as those of other European fossils, for example, Steinheim, Ehringsdorf, Krapina and Saccopastore, do not justify their specific separation from *Homo sapiens*[4]. This view, then, while acknowledging the sapient features of Swanscombe and Fontéchevade, does not differentiate them taxonomically from forms which Prof. Vallois would classify as pre-Neanderthals, and it regards classic Neanderthal man as comprising an aberrant evolutionary line which left the precursors of modern man when they had already attained a stage at which they were indistinguishable from *Homo sapiens*.

PLANT ECOLOGY OF ANCIENT PERIODS

THREE palæobotanists contributed papers to a symposium on palæoecology held at the Linnæan Society on March 19. They agreed on a wide definition of ecology, being ready to include almost anything that could be learnt from plant fossils, apart from their taxonomy and their morphology. After that, each speaker went his own way and confined himself to material he had studied in both the field and laboratory.

Dr. Kathleen Chesters spoke about the Tertiary floras of the coastal parts of Kent, Sussex, Hampshire, Dorset and Devon. She emphasized how difficult collecting has now become in this stretch of coast; and also dealt with the cliffs of Mull, where one can do little without explosives (Starkie Gardener, the pioneer, used dynamite). She dealt mainly with the nature and validity of evidence; apart from deductions from geology and from fossil animals, we have two main kinds of evidence from plants.

First, there is ecological form and ecological anatomy. The plant world of the Tertiary seems so like our own, and plants appear to have changed so little that we can reasonably use arguments based on the modern plant world. For example, we know that the proportion of trees with leaves (or leaflets) with entire margins increases from cool climates to the tropics. Then, also, leaves with drip tips are much commoner in rainy than in dry climates. Growth rings in wood indicate seasonal growth, and to-day, usually a winter resting season. All this evidence is available without a specific or generic determination, but where there is such determination it is possible and legitimate to inquire in what climatic zones most of the genera flourish to-day; or even in what country they are found. Where both lines of evidence coincide, as in general they do, one has impressive evidence. Dr. Chesters briefly made a case for likening the Eocene floras to those of Malaya, but the Mull flora (not yet securely dated) to the warm temperate floras of China and Japan.

Prof. T. M. Harris (Reading) said that the corresponding arguments were largely useless in the Jurassic because nothing like the Jurassic flora exists anywhere on earth. A quarter of the species belong to extinct families and the rest to relic families (like *Gingko* and *Thyrsopteris* and *Matonia*). Gymnosperm leaves are too different from those of angiosperms to allow reasonable comparison of their ecological form, and he suggested that the more tender ones were simply deciduous and the tough ones evergreen. He could not answer reasonable questions about past climates, but could only supply unexpected ecological crumbs, such as that forest fire was widespread and rather frequent in the Jurassic.

In the Yorkshire Deltaic flora the frequency of ferns might indicate a humid atmosphere, but the rarity of epiphytes rather suggests dryness. He showed that the Delta included three floras, swamps of *Equisetum*, often preserved intact; trees and herbs of the river banks represented by detached leaves but nowhere preserved as they grew, and, finally, tiny plant fragments. These last are the most varied, numerous and widespread and may represent floras of inland habitats washed down by occasional floods.

Dr. W. S. Lacey (Bangor) dealt with his recent experiences when collecting in the Karoo series of the Upper Zambezi in Southern Rhodesia. He drew more on geological evidence than the previous speakers. This great series of inland origin extends from the Upper Carboniferous to the Jurassic. It begins, as in South Africa, with Dwyka glacial deposits (tillites and varved clays), but farther north in Nyasaland there is no glacial deposit but only torrent-carried boulders.

The earliest floras are too little known to be useful, but the succeeding rich flora of Upper Wankie sandstone and the 40-ft. thick coal seam are taken to indicate good conditions for plant growth. The admixture of *Glossopteris*, *Gangamopteris* and of Northern (mostly European) Upper Carboniferous or Lower Permian species was also held to indicate warmth, since they are supposed to have lived in a very warm climate in Europe. Later stages, though still with a rich *Glossopteris* flora, have lost both the genus *Gangamopteris* and the Northern species. They are followed by Triassic floras with *Dicroidium* and the conifer-like *Dadoxylon* the growth rings of which seem significant. Still later there are freshwater concretionary limestones which may indicate evaporating lakes, and finally extensive fossil sand dunes indicating a hot, dry desert.

Dr. Lacey said he hesitated to regard *Gangamopteris* as an indicator of a glacial or even cold climate. He thought the whole sequence indicated a progressive warming and desiccation of the climate, though interrupted by seasonal torrential rains. At several stages no plants are known, but their presence is indicated by herbivorous reptiles, and the appearance of Crustacea characteristic of the European Carboniferous may indicate considerable warmth in the later stages.

In the discussion (which proved to have needed more time than was allotted) many observations were made. Dr. Chesters confirmed the existence of mangroves in the English Eocene and also stated that epiphytes had still not been found. There were apparently opposed statements about the rate of decay of plant remains in tropical muds which called for a series of experiments to find out the truth. One of the Upper Karoo plants (*Lepidopteris stormbergensis*) was compared with a modern waterside aquatic herb, with which it agrees in that some small leaves, presumed to be lower ones, have more numerous stomata above than below. Its other leaves are normal. Others pointed out that limestones are forming to-day in East African lakes quite apart from evaporation of the water.

Dr. Hamshaw Thomas ended the discussion fittingly by suggesting that the early floras, like none on earth, grew in climates like none on earth to-day, but just how these climates differed he left us to ponder.

TOM M. HARRIS

WEATHER MODIFICATION IN THE UNITED STATES

THE National Science Foundation has recently initiated a programme in which 1,130,000 dollars will be distributed in thirteen grants for laboratory research, field experiments and conferences on meteorological methods directed toward modification of weather. The programme aims at an intensive study of the scientific basis of weather control, through the support of scientists working in cloud physics and allied fields.

Seven of the grants will make extensive use of experiments in the field to study the formation and characteristics of clouds, and possible changes in clouds induced by man.

Horace R. Byers and Roscoe R. Braham of the Department of Meteorology, University of Chicago, have received a grant of 114,300 dollars for a study of the physical effects of silver iodide seeding over the Great Plains. Cloud seeding in mountainous areas of the Pacific coast appears to result in measurable increases in precipitation. Over the flat terrain of the Great Plains, however, positive results have not been shown. This project will therefore release silver iodide nuclei from aircraft and investigate the resultant physical changes in the clouds themselves, rather than attempt to measure statistical departures in precipitation.

A. Richard Kassander, Louis J. Battan, and James E. McDonald of the Institute of Atmospheric Physics, University of Arizona, have received a grant of 161,800 dollars to study the physics of clouds and of cloud modification. In recent cloud-seeding experiments it was discovered that mean rainfall was approximately 30 per cent higher on seeded than on non-seeded days, and lightning flashes were about nine times more numerous on seeded days. These investigations will continue in an attempt to improve knowledge of the development of clouds, precipitation and electrification.

Robert D. Elliott of Aerometric Research, Inc., Goleta, California, will conduct an investigation of precipitation processes and efficiency of Pacific coast storms with a grant of 90,500 dollars. Statistical data on west coast storms are already available from the Statistical Laboratory of the University of California at Berkeley, and elsewhere. An intensive effort will now be made to obtain physical data on west coast storms, including water content, nuclei number, potential gradient, and standard meteorological parameters. This will then be combined with the statistical data to develop, it is hoped, a complete model of a west coast storm.

Dwight B. Kline of the United States Weather Bureau, Department of Commerce, will direct an 18-month programme with a grant of 68,900 dollars, on synoptic observations and studies of freezing nuclei anomalies. It has been observed that about 30 days after known meteor showers on the Earth, a peak is reached in the number of freezing nuclei in clouds, in widely separated geographical locations. Other apparent coincidences between meteor showers and freezing nuclei have been noted. The U.S. Weather Bureau will conduct a systematic collection of results on freezing nuclei taken at widely scattered places at the same time. It is hoped that definitive information on the effects of meteoric dust on cloud nuclei can be obtained from this study.

The Atmospheric Research Group of Pasadena, California, will receive a 57,100 dollar grant to conduct field studies in cloud physics related to nucleation, hydrometeor development, electrification, and cloud dynamics. Field studies of small, 'simple' clouds will be conducted to investigate the effects of time, temperature, humidity, and drop-size on nucleation. Cloud seeding will be used as a research tool, most of the field measurements being carried on in the region of Flagstaff, Arizona.

The National Science Foundation has transferred 50,000 dollars to the Office of Naval Research in support of cloud electrification studies by A. D. Little, Inc., under the direction of Bernard Vonnegut. This work involves studies of the precipitation process and the processes at work in the electrification of thunderstorms.

Meteorology Research, Inc., will receive, subject to satisfactory completion of negotiations, a 40,000 dollar contract for two-year cloud-physics studies at Santa Barbara, under the direction of Paul MacCready, using radar to describe individual storms in great detail, to determine differences between storms, and formulate hypotheses on the relative seedability of various storms.

A laboratory project will be carried out in the Department of Meteorology of the University of Chicago, where Horace R. Byers has received a three-year grant of 383,700 dollars for research in cloud physics, covering the factors believed to be important in precipitation mechanisms: particles and nuclei, ice nucleation processes, and the growth of ice crystals and water droplets.

Two grants have been made for statistical evaluation of cloud-seeding experiments. J. Neyman of the University of California at Berkeley will direct a group in the Statistical Laboratory on randomized cloud-seeding experiment under a two-year grant of 64,900 dollars. Such experiments have been conducted for two years in Santa Barbara and Ventura counties, and will be continued. The data available will be subjected to statistical scrutiny independent of any *a priori* hypotheses concerning the distribution of rainfall, using non-parametric statistical methods with the aid of a high-speed computer.

Max A. Woodbury of the Department of Mathematics, New York University, will make a two-year study of the statistical evaluation of weather modification with a grant of 58,800 dollars.

Three grants in support of conferences have also been made. The American Geophysical Union has received 25,000 dollars for a conference on "Mechanisms of Precipitation Formation". The National Academy of Sciences–National Research Council has received 10,000 dollars for a conference on the "Design and Conduct of Research Programmes in Weather Modification", under the direction of S. S. Wilks of the Division of Mathematics. The Foundation for Instrumentation Education and Research received 5,100 dollars for a conference on "Instrumentation for Cloud and Weather Modification".

PERSONNEL MANAGEMENT IN PERSPECTIVE

An inquiry into the reasons why modern personnel management is experiencing a crisis in its development, and why it is not producing better work through happier employees, has recently been made by Col. L. Urwick*. The major weakness in modern personnel management is, he suggests, its lack of integration into the organizational structure of businesses. There are many historical reasons for this trend and it needs urgent remedying. The corrective needs to be introduced at the very top of industry, by the leaders of business themselves.

The final strength of a business is no more than the collective strength of the individuals composing it. This has been known for years and in the past two decades business has invested millions of pounds in various schemes of personnel management. The expected results have not been achieved. The work-force remains obstinately unmoved, and management itself has its doubts. One reason is that business still looks on its employees as 'economic men' seeking exclusively economic objectives, whereas in reality social objectives are more important to most employees. Another reason is that employees are seen as individuals and not as members of a social group. The effort of personnel management is not directed towards achieving high morale through the social group. The test of a good personnel policy is high morale, a matter not so much of doing things materially for employees, as of stimulating them to achieve something together. High morale requires, above all, leadership from the chief of the enterprise.

Historical trends have weakened the leadership content in personnel management. Personnel activities have become something 'tacked on to' a business because of the need for specialization, and this has prevented the personnel officer from obtaining the authority which should have accompanied his specialized responsibility. The solution is to make the 'line' manager at every level more directly responsible for personnel activities, using the personnel officer more fully for advice.

'Line' managers, especially at the heads of businesses, have found themselves overloaded in attempting to discharge their personnel responsibilities. The solution is to develop the use of general staff officers who can relieve their chiefs of details in all their functions. The possibilities here have long been understood by the Armed Services but are still not exploited in business.

Personnel management has suffered from the growing pains of the new kind of management, which acknowledges a much greater social responsibility, but is fitful in its efforts to shoulder the new burdens. Personnel men were given sometimes too much authority, sometimes too little. The solution is patient, sustained and prudent effort over many years by business leaders to get a personnel policy working well within their organization.

HÆMATOLOGY

A NUMBER of the *British Medical Bulletin* (15, No. 1; 1959) has attempted to review some of the many important advances that have been made in hæmatology in the past few years. This, in a series of fourteen articles, the contributors have done in a most stimulating and readable manner. The subject-matter covered includes the deficiency anæmias, the chemistry of normal and abnormal hæmoglobins and their inheritance, hæmolytic anæmias, the leukæmias, the life-history of the lymphocytes and bone marrow culture.

Many of these reviews are particularly stimulating. The description of the life-history of the lymphocytes, cells which hitherto have been somewhat mysterious cells, shows that the usual concepts of their life within the body must be reconsidered.

Normal hæmoglobin synthesis is presented in contrast to a description of the chemistry of the abnormal hæmoglobins. Modern methods of electrophoresis and chromatography have shown that the sole difference between normal adult and sickle-cell hæmoglobin lies in the substitution of one amino-acid for another in one of their constituent peptides. Similarly, the exact defects in other abnormal hæmoglobins are being elucidated.

The alterations of red cell structure in other forms of hæmolytic anæmias are described where (either due to inherited or acquired defects) chemical changes in the lipoid, protein, glutathione or glycolytic systems can be demonstrated. Other aspects of the hæmolytic mechanisms are covered by reviews of the latest modifications in our knowledge of the serology of acquired hæmolytic anæmias, and descriptions of the methods of determining red cell survival and the sites of red cell sequestration using radioactive chromium-51.

The topical problem of the factors that are implicated in the causation of leukæmia are discussed together with the latest methods of treatment in chronic leukæmia.

In these articles faults and omissions are few, but the effects of ionizing radiation in the causation of leukæmia could have been discussed more fully in view of the current national and medical interest in this subject. The reader is left in some doubt as to the exact percentage of fœtal hæmoglobin that can be accepted as abnormal. Similarly, it has not been clarified whether folic acid-levels can be measured in plasma or serum of normal persons not receiving folic acid therapy, a point of considerable importance in the recognition of folic acid-deficient states.

This number of the *British Medical Bulletin* is a valuable addition to the literature of hæmatology and should be read by all practising hæmatologists and by all clinicians, biochemists and students who have an interest in this ever-growing subject. A. A. SHARP

IDENTITY OF THE α-CHAINS OF ADULT AND FŒTAL HUMAN HÆMOGLOBINS

By J. A. HUNT

Medical Research Council Unit for Molecular Biology, Cavendish Laboratory, Cambridge

THE globins of human fœtal and adult hæmoglobins (hæmoglobins F and A) are known to differ in several ways[1a,b]. Hæmoglobin F contains more threonine, serine, methionine and tryptophan, and less proline, alanine, valine and histidine than hæmoglobin A; it also contains *iso*leucine not present in purified samples of hæmoglobin A[1b,2]. Hæmoglobin F is more stable to alkali than hæmoglobin A[1b], and in the erythrocyte hæmoglobin F has a greater affinity for oxygen[1a].

Hæmoglobin F was shown by Schroeder and Matsuda[3] to consist of two pairs of polypeptide chains with N-termini, valyl–leucine and glycine. Since Rhinesmith *et al.*[4] had shown that hæmoglobin A consists of two pairs of polypeptide chains with N-terminal sequences valyl–leucine and valyl–histidyl–leucine, called the α- and β-chains, it was suggested that the valyl–leucyl (α) chains of hæmoglobins A and F might be identical[3]. I have separated and compared these chains and find that, so far as can be judged by the methods used, they are indeed identical.

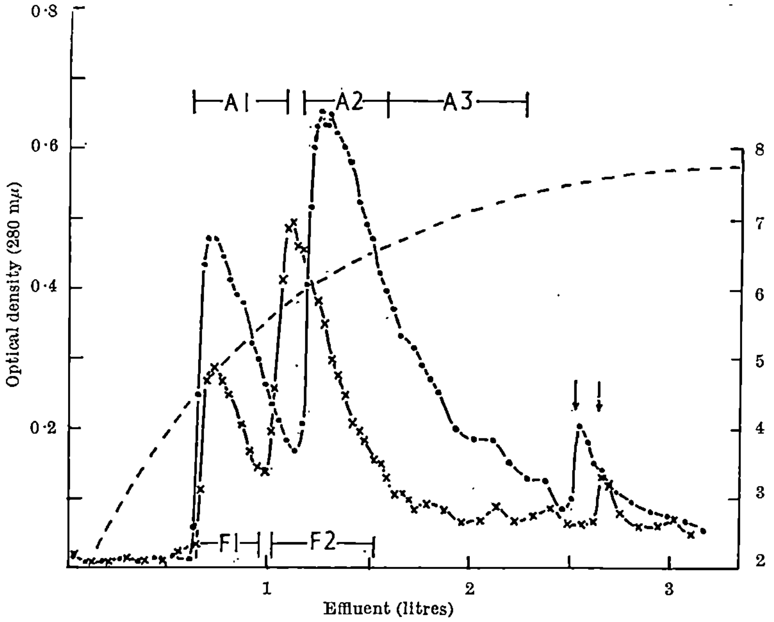

Fig. 1. Chromatograms of the globins A (700 mgm.) and F (300 mgm.) on '*IRC* 50' resin. The urea gradient was made by running 8 *M* urea at *p*H 1·9 into 1 litre of 2 *M* urea at *p*H 1·9. Because of the uncertainty of locating the exact starting point of the urea gradient, the positions of the peaks *A*1 and *F*1 have been adjusted slightly to coincide exactly. The two arrows mark the points at which 8 *M* urea at *p*H 1·9 was used to complete the elution. — · — · —, globin A; —×—×—, globin F; – – – –, urea

Hæmoglobin F was separated from cord-blood oxyhæmoglobin by chromatography on a column of 'Amberlite *IRC* 50'. Using a buffer (composition 3·9 gm. $NaH_2PO_4.2H_2O$ plus 2·66 gm. Na_2HPO_4 per litre), which had had its *p*H adjusted to 7·18 at 25° C. with 2 *N* potassium hydroxide, hæmoglobin F was eluted at the solvent front[5].

The constituent polypeptide chains of the globins, prepared by the method of Anson and Mirsky[6], were separated by gradient elution with urea at *p*H 1·9 on an 'Amberlite *IRC* 50' column[7]. The chromatograms of both globins show two peaks (Fig. 1), allowing fractions *A*1, *A*2 and *A*3 and *F*1 and *F*2 to be isolated. Fraction *A*3 contains less of fraction *A*1 as an impurity than fraction *A*2 and so was used in preference to *A*2.

After dialysis and lyophilization the fractions were subjected, without further denaturation, to tryptic digestion and chymotryptic digestion of the trypsin-resistant cores, in an autotitrator[8,9] using a ratio of enzyme to protein of about 1 : 100. The resulting peptides were separated by electrophoresis, followed by chromatography using Ingram's 'fingerprint' technique[8].

Fig. 2 shows 'fingerprints' of the tryptic digests of fractions *A*1 and *F*1 and the chymotryptic digests of their trypsin-resistant cores. The patterns are seen to be identical. Their identity was further confirmed by specific tests for arginine, histidine, tryptophan,

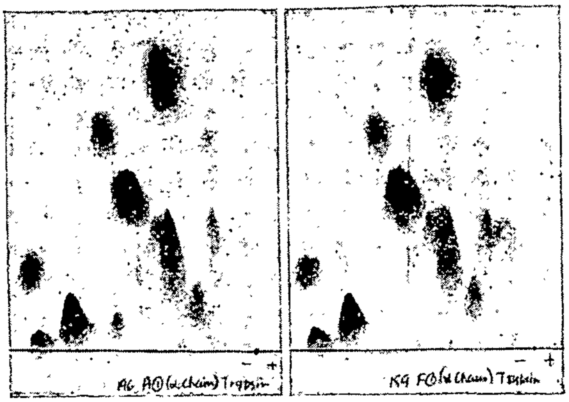

Fig. 2*a*. 'Fingerprints' of the tryptic digestions of fractions *A*1 and *F*1

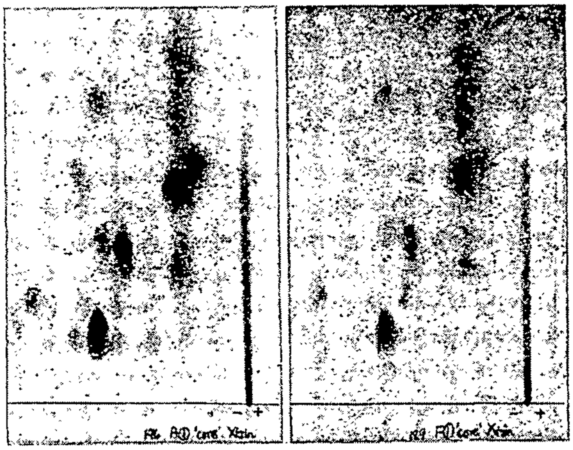

Fig. 2*b*. 'Fingerprints' of the chymotryptic digestions of the trypsin-resistant cores of fractions *A*1 and *F*1

tyrosine and sulphur[10], and by the identity of the ratios of tyrosine to tryptophan determined spectrophotometrically[11] (Table 1).

The N-terminal end-groups of the chains were determined allowing the fractions in 8 *M* urea to react with 1-fluor-2.4-dinitrobenzene at *p*H 8 and 38° C. (ref. 12). Table 2 shows that, on hydrolysis for an hour, dinitrophenyl valyl–leucine is the main product from *F*1 and dinitrophenyl glycine from *F*2. Since *F*1 is the same as *A*1, it must correspond to the α-chain of hæmoglobin A as defined by Rhinesmith *et al.*[4]. Hydrolyses for 15 min. of the dinitrophenylated fractions *A*1 and *A*3 showed that *A*1 contained mainly N-terminal valyl–leucine, confirming that it is the α-chain, while *A*3 contained virtually none. It was not possible to isolate di-dinitrophenyl valyl–histidyl–leucine. These results for *A*1 are in agreement with those of Ingram using the Edman degradation[13]. Leucine and *iso*leucine were separated from 22-hr. hydrolysates of fractions *F*1 and *F*2 on a one-dimensional chromatogram using 1 : 1 benzyl : butyl alcohol buffered at *p*H 8·4 (ref. 14). Measurements of the ninhydrin coloration eluted from the chromatogram showed that the ratio of *iso*leucine to leucine is less than 1 : 100 in *F*1 and approximately 1 : 6 in *F*2.

Table 1. Ratio of Tyrosine to Tryptophan of Fractions *A*1 and *F*1 determined by two different Methods

(*a*) Spectrophotometric determination, average of two values.
(*b*) Determined by specific stains on 'fingerprints'.

Fraction	(*a*) $\frac{\text{Tyrosine}}{\text{Tryptophan}}$	(*b*) No. of peptides containing: tyrosine	tryptophan
*A*1	3·0	3	1
*F*1	3·1	3	1

Table 2. Amounts of Dinitrophenyl Peptides and Amino-acids determined Spectrophotometrically, by Elution from a Paper Chromatogram, from 1 hr. Hydrolysates of the Dinitrophenylated *F*1 and *F*2 Fractions

val, valine or valyl; leu, leucine; gly, glycine

Fraction	Dinitrophenyl derivatives			
	O.D. 350 mμ	O.D. 360 mμ		$\frac{\text{val–leu + val}}{\text{val–leu + val + gly}}$
	val–leu	val	gly	
*F*1	0·71	0·12	0·02	0·98
*F*2	0·16	0·03	1·05	0·15

Fingerprints of the *F*2 and *A*3 fractions show many differences, which account for all the differences in the fingerprints of the whole globins A and F (Fig. 3).

Ingram has shown[13] that the amino-acid changes which characterize the mutant hæmoglobins S, C, Dβ and E occur in peptides of the β-chain of hæmoglobin A, whereas those of hæmoglobins I and Dα occur in the α-chain. In order to account for the genetic data of a family carrying the genes for hæmoglobins S and G, Schwartz *et al.*[15] proposed that there are two genes controlling the synthesis of hæmoglobin A; and the same proposal has been used by Smith and Torbet[16] in their study of Hopkins-2 hæmoglobin. Neither hæmoglobin G nor Hopkins-2 hæmoglobin has yet been characterized chemically, but it is possible that each of the two genes controls the synthesis of one of the chains of hæmoglobin A. If so, then the synthesis of each of the chains of hæmoglobin

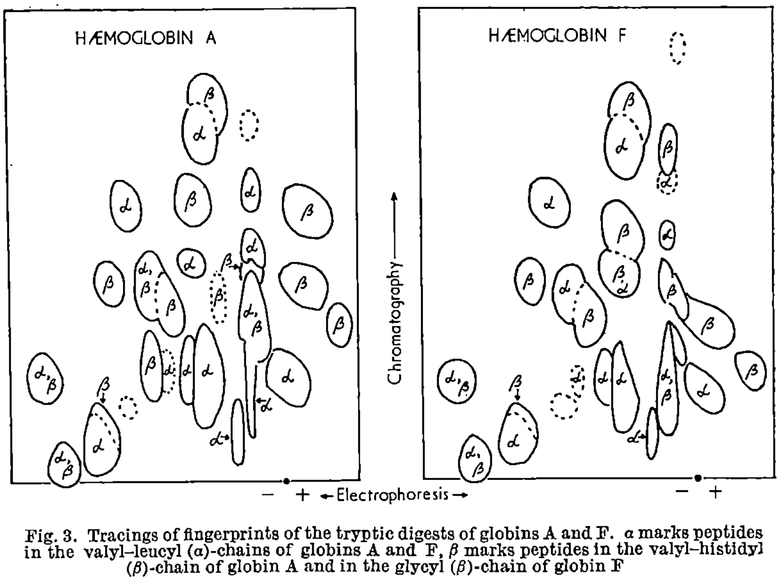

Fig. 3. Tracings of fingerprints of the tryptic digests of globins A and F. α marks peptides in the valyl–leucyl (α)-chains of globins A and F, β marks peptides in the valyl–histidyl (β)-chain of globin A and in the glycyl (β)-chain of globin F

F may also be controlled by a different gene, which would suggest that the α-chains of hæmoglobins A and F are controlled by the same gene. This possibility could be tested by studying the hæmoglobin F from individuals carrying hæmoglobins with α-chain mutations, such as[13] hæmoglobins I or Dα. If the same gene controls the synthesis of the α-chains of both the fœtal and adult forms, an abnormal fœtal hæmoglobin would be found. In individuals carrying mutations in the β-chain of adult hæmoglobin, the fœtal hæmoglobin is apparently normal, as is to be expected. On the other hand, one would predict the existence of abnormal fœtal hæmoglobins containing β-chain mutations associated with normal adult hæmoglobins[17]. Furthermore, only the gene controlling the β-chain would be affected in the switch-over from fœtal to adult hæmoglobin synthesis. The hæmoglobin system therefore offers opportunities for studying the control mechanism of gene action.

I thank Dr. Rayburn and the staff of the Cambridge Maternity Hospital for generously supplying the samples of cord blood, and Drs. Smith and Wilson (Ottawa) for allowing me to see the manuscript of their paper before publication. I am much indebted to Drs. S. Brenner and M. F. Perutz for their helpful discussions and encouragement.

I am grateful to the Medical Research Council for a Scholarship.

Note added in proof. I have just learnt that Drs. J. R. Vinograd and W. A. Schroeder, at the California Institute of Technology, have obtained similar results by a different method.

DARK FIXATION OF CARBON DIOXIDE IN *KALANCHOE BLOSSFELDIANA* IN RELATION TO PHOTOPERIODISM

By Dr. G. ZABKA*, Prof. F. G. GREGORY, F.R.S., and Dr. J. EDELMAN

Research Institute of Plant Physiology, Imperial College of Science and Technology,
London, S.W.7

PREVIOUS work[1] has shown that in *Kalanchoe blossfeldiana* var. Tom Thumb the capacity for dark fixation of carbon dioxide developed after previous exposure to a number of short days (> 13) and failed to develop either in long days or if the dark period was interrupted by an exposure of 10 min. to light given at midnight. Flower induction results only under the former conditions.

In a cycle of 8 hr. light and 16 hr. darkness the course of fixation of carbon dioxide during the dark period, using gas-analysis methods, showed that the rate of this process increases from zero at the beginning of the dark period and reaches a maximum after approximately 12 hr. (the critical dark period for flower induction), after which dark fixation rapidly falls off and gives place after 16 hr. to normal respiration, which is maintained at a nearly constant rate for a further 32 hr. of continuous darkness. This behaviour of induced plants of *K. blossfeldiana* var. Tom Thumb is in marked contrast with that of other succulent plants[2–4], in which the rate of uptake of carbon dioxide remains constant for several hours after darkening. For this reason the work here reported was undertaken to confirm previous findings.

In the course of this work it was found that there are marked varietal differences in the species *K. blossfeldiana*. The variety Feuer Blüte behaved in the normal 'Crassulacean' way in that dark fixation during the first 4 hr. of darkness was already maximal and slowly declined. Furthermore, in this variety the capacity to fix carbon dioxide in darkness was independent of the photoperiodic regime given, and indeed was greater in long than in short days.

The method consisted in exposing the tissue to carbon dioxide labelled with carbon-14 of known concentration and estimating the dark fixation by extracting the tissue at the end of the experiment with alcohol and estimating the radioactivity of the extract in the usual way.

The apparatus used was a 50-ml. conical flask with a centre well. The flask was sealed with a rubber serum cap and immersed in darkness in a water-bath at 20° C. It was possible to maintain a known concentration of unlabelled carbon dioxide by ventilation through two hypodermic needles inserted through the cap, one of which was attached to a gas cylinder. The tissue was contained in the annular space on wet filter paper to avoid injection. At various times during the dark period a known volume of labelled carbon dioxide was released from labelled sodium carbonate contained in the centre well by injecting excess of lactic acid through the cap from a hypodermic syringe ; immediately prior to this some air free of carbon dioxide was flushed through the flask and then the ventilating needles were removed. The exposure to labelled carbon dioxide was continued for 1 or 4 hr. periods. At the end of the period the tissue was immediately killed by adding boiling 80 per cent ethanol and complete extraction ensured by two further extractions. The extract was evaporated to small volume in a vacuum desiccator and cleared by centrifugation; the precipitate contained no carbon-14. Aliquots of the supernatant liquid were dried on duralumin counting plates and radioactivity estimated with an end-window counter. The disks, which contained little radioactivity after extraction, were dried and weighed. Results were calculated on the basis of infinite thinness and expressed as μl. carbon dioxide fixed per mgm. dry weight of extracted disk per hour.

---

* Present address: Department of Botany, State University of Iowa, Iowa City, U.S.A.

Plants used for the experiments were raised from cuttings of uninduced plants in growth chambers at 20° C. provided with fluorescent tubes giving an intensity of 1,000 ft. candles at the leaf surface. The short-day plants were given either 8 or 9 hr. and the long-day plants 16 hr. light periods. Preliminary experiments showed that it was necessary accurately to select leaves of the same age by using those from a known number of nodes below the apex.

Experiment with Variety Feuer Blüte

In this experiment, samples of 30 disks of 7 mm. diameter were taken from leaves of the upper ten nodes. The induction period was 97 days, by which time the short-day plants had produced numerous flower buds, while the long-day plants remained vegetative. Dark fixation was studied over four consecutive 4-hr. periods. During the previous light period the plants were exposed to full sunlight in a greenhouse. At the end of the light period, disks were immediately cut and placed in the flasks. The course of dark uptake over the first 16 hr. is shown in Table 1.

Table 1

	Interval of darkness during exposure to $^{14}CO_2$	μl. CO_2 fixed/mgm. dry wt./hr..
Short-day	0–4 hr.	0·55
	4–8 ,,	0·50
	8–12 ,,	0·53
	12–16 ,,	0·27
Long-day	0–4 hr.	0·85
	4–8 ,,	0·58
	8–12 ,,	0·64
	12–16 ,,	0·41

This shows that the maximal rate of dark fixation occurred in the first period, after which there was no marked change until 12 hr. darkness; it then declined. Dark fixation was actually greater in the long-day than in the short-day plants. In this respect the variety Feuer Blüte behaved as a normal succulent.

Experiments with Variety Tom Thumb

In a similar experiment the variety Tom Thumb was used. The short-day plants received a preliminary induction period of 75 days (9 hr. light, 15 hr. dark) in the growth chamber (1,000 f.c., 20° C.); visible flower buds appeared after 45 days. For each sample, 20 disks (7 mm. diam.) were used, taken from leaves of the upper eight nodes, and equally distributed among the treatments. Duplicate samples were taken from pairs of opposite leaves.

The long-day plants received 18 hr. light per day and were all vegetative at the time of sampling.

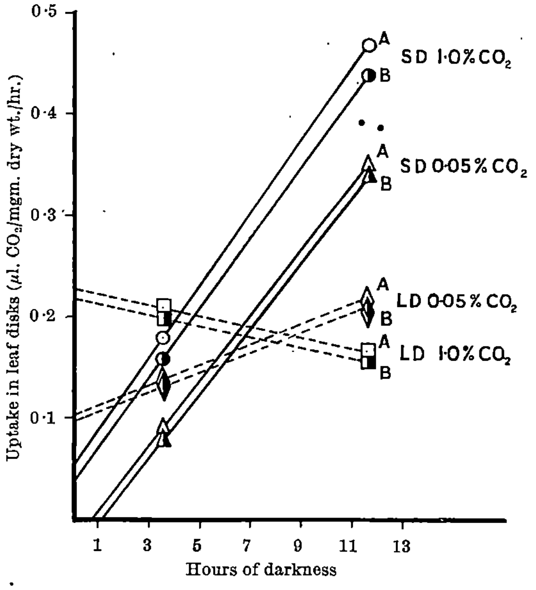

Fig. 1. Dark fixation of carbon dioxide by leaf disks of variety Tom Thumb; long-day and short-day plants. Half-shaded symbols denote duplicates

3 hr. after the beginning of the dark period one set of disks was exposed for 1 hr. to two concentrations of labelled carbon dioxide: 0·05 and 1·0 per cent, respectively. A second set was exposed after 11 hr. in darkness, at which time the dark uptake was expected to have attained a maximum. The results are shown in Fig. 1, in which results for duplicate samples in each treatment are given. In the short-day plants (S.D.) the rate of dark uptake is nearly proportional to the duration of darkness as the lines pass close to the origin. The long-day plants (L.D.) at both levels of carbon dioxide showed greater uptake than the short-day plants at the earlier period and maintained the level of uptake at similar rates in the later period. The unexpected results appear that, using disks, the long-day leaves showed appreciable dark uptake from the beginning of the dark period, whereas the short-day leaves again showed an increase from zero time.

As the earlier experiments of Gregory, Spear and Thimann[1] were performed with whole cuttings and the leaves were therefore entire, it seemed important to repeat the experiment using intact leaves. In other respects the experiments were similar to those already described.

The experiment was carried out on two occasions. In the first, 1 per cent carbon dioxide was used

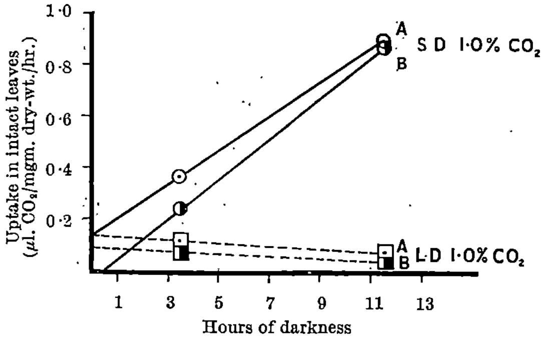

Fig. 2. Dark fixation of carbon dioxide by whole leaves of variety Tom Thumb. Half-shaded symbols denote duplicates

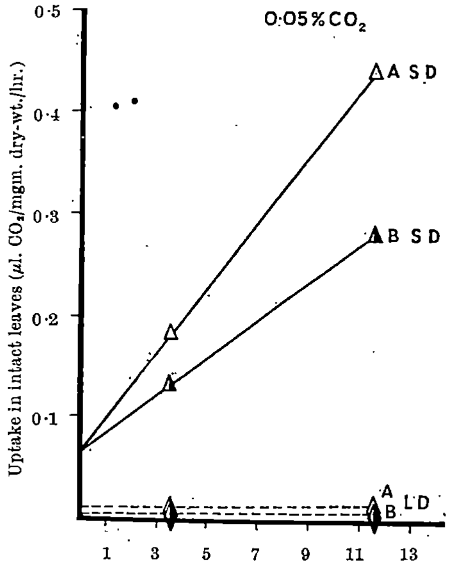

Fig. 3*A*. Dark fixation of carbon dioxide by whole leaves of variety Tom Thumb. Half-shaded symbols denote duplicates

with leaves from specific upper nodes for the earlier sample, and the opposite member of the leaf pairs from the same nodes for the later sample. Duplicate samples were taken from alternate nodes on the stem. The results are shown in Fig. 2. The rate of uptake of the intact long-day leaves was now less than that of short-day leaves, whereas the latter behaved as in the experiment using leaf disks.

Since the original experiments with whole cuttings were carried out in normal air, the second experiment employed two concentrations of carbon dioxide—1 and 0·05 per cent. Results are shown in Fig. 3 *A* and *B* and confirm previous findings.

Evidence has been presented from four experiments, all showing that the rate of dark uptake of carbon dioxide in the variety Tom Thumb after short-day induction increases through the dark period up to 12 hr., and begins at a very low level. In the long-day plants the uptake appears to be different, using disks as compared with entire leaves,

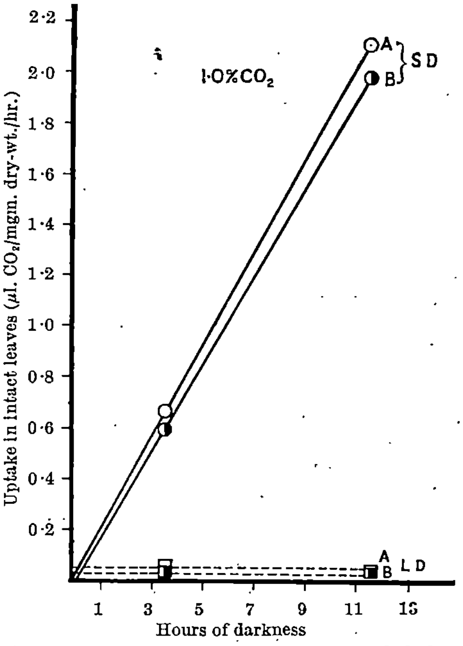

Fig. 3*B*. Dark fixation of carbon dioxide by whole leaves of variety Tom Thumb. Half-shaded symbols denote duplicates

the former showing much higher rates of fixation, which is maximal at the start of the dark period. The experiments with entire leaves confirm the findings of Gregory *et al.*, but the cause of the discrepancy between disks and entire leaves cannot at present be explained. The carbon dioxide which has direct access to the tissues through the cut edges of the disks is thus not subject to stomatal control; this may be important if stomatal behaviour in the dark varies between long- and short-day leaves as previously suggested[1].

MODEL OXYGEN-CARRYING COMPOUNDS AND THE IRON-*BIS*-INDIGO COMPLEX

By L. F. LARKWORTHY and Prof. R. S. NYHOLM, F.R.S.

William Ramsay and Ralph Forster Laboratories, University College, London, W.C.1

ONE of the most challenging problems of biological chemistry is to explain adequately the ability of hæmoglobin to combine reversibly with molecular oxygen without undergoing oxidation. A closely related problem is the orientation of the oxygen molecule in oxyhæmoglobin. X-ray methods have not yet yielded this information, chiefly because of the complexity of the protein part of the molecule. Consequently, considerable interest attaches to those metal chelate complexes which can combine reversibly with oxygen to yield crystalline compounds. Many such compounds have been suggested as possible models for hæmoglobin; among these is a complex of iron and indigo which has been widely quoted as being capable of reversible combination with oxygen when in solution in pyridine. We have been investigating the chemistry of this complex, but before discussing our results, some relevant aspects of the problem will be summarized.

When hæmoglobin is oxygenated, the bivalent iron atom is not oxidized to the tervalent state but the effective magnetic moment decreases from 5·4 Bohr

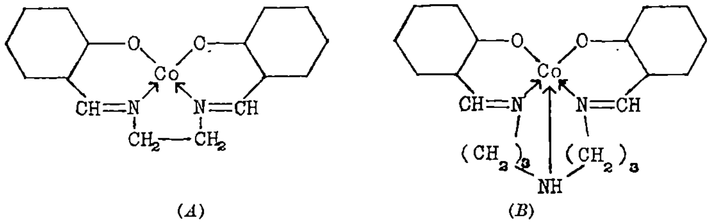

Fig. 1

magnetons (B.M.) to zero[1]. This indicates the formation of a spin-paired (inner orbital $3d^2 4s 4p^3$) octahedral complex. The behaviour of other metal complexes which combine with oxygen is relevant to the hæmoglobin problem. Thus, cobaltous *bis*-salicylaldehyde ethylene diimine (Fig 1, *A*) and chromous *bis*-acetylacetone[2] both absorb oxygen readily ; but only in the former case is the combination with oxygen reversible. Extensive investigations of oxygen-carrying cobalt complexes have been carried out by Calvin[3] and by Diehl[4] on many compounds derived from *A* and *B* ; also, Hearon[4] has studied the *bis*-histidinocobalt (II) complex. When oxygenated these paramagnetic cobalt (II) complexes decrease in susceptibility and, although the results are not easy to interpret, apparently spin-pairing occurs between the cobalt and oxygen atoms.

The aquopentamminocobalt (II) and aquotetraethylenepentamminocobalt (II) ions[5,6], and also[7] vitamin B_{12a}, have been reported to combine reversibly with oxygen under suitable conditions. The first of these is stated to show magnetic behaviour similar to that of the cobalt (II)–histidine compound. Vitamin B_{12a} is claimed to be the first cobalt (III) compound to combine reversibly with oxygen. The magnetic properties of these unusual compounds warrant investigation.

In oxyhæmoglobin the metal-porphyrin skeleton is small compared with the attached protein. Indeed, there is some evidence for believing that the hæm molecule is buried within the protein. For example, whereas the combining powers of ethyl *iso*cyanide, *iso*-propyl *iso*cyanide, and *t*-butyl *iso*cyanide with hæm are about the same, both hæmoglobin and myoglobin combine much more strongly with the smaller ethyl *iso*cyanide than with the larger *t*-butyl *iso*cyanide[8]. Crystallographic studies have shown that the iron atom is in a 'cleft' in the protein of myoglobin[9], and electron magnetic resonance investigations indicate that the normal to the hæm plane passes to the exterior of the molecule from the iron atom in the cleft[10]. Since the movement of an oxygen molecule to and from the iron atom in hæmoglobin is unlikely to be sterically hindered, Wang[11a] has suggested that the stability of oxyhæmoglobin compared with that of 'oxyhæm' is due to the presence around the iron atom of a region of low dielectric constant produced by hydrophobic groups of the protein. Then, he claims, the separation from the iron atom of the O_2^- ion, necessary for an oxidation process, cannot occur readily but neutral molecules have easy access. However, such a region of low dielectric constant can scarcely affect the relative stabilities of oxyhæmoglobin and oxyhæm ; and although it would produce a high potential barrier to the separation of ions, this is a kinetic rather than a thermodynamic difficulty. Other factors such as the effect of the ligands on the oxidation potentials of the iron atoms in the two compounds seem far more important. In this the imidazole group of the protein, which completes the co-ordination shell of the iron atom in hæmoglobin, must play an important part.

A knowledge of the orientation of the oxygen molecule with respect to the iron atom of the hæm would give valuable insight into the type of the bond between them. If the oxygen molecule is held parallel to the hæm plane, then the bond involved would presumably be similar to the multi-centre type found in ethylenic co-ordination compounds, for example $[PtCl_2.C_2H_4]_2$. (This structure is favoured by Griffith[11b] for theoretical reasons.) On the other hand, if it lies at right angles to the hæm plane, it is presumably held by a σ-bond end on to one atom together with possible dative π-bonding from the metal. A homonuclear molecule like oxygen would be expected to be held either at right angles to or parallel to the hæm plane (Fig. 2) : a heteronuclear molecule like nitric oxide would be expected to be at right angles to, or at a much smaller angle to, the hæm plane. Thus, several nitrosyls have been found to contain linear metal–N–O bonds[12] ; and one, $Co(NH_2CSSH)_2NO$, has been found[13] to have a metal–N–O bond angle of 135° with respect to the plane formed by the sulphur atoms of the thiocarbamate groups. However, Ingram[14] has reported, from preliminary electron magnetic resonance investigations, that the axis of the nitric oxide molecule in the nitric oxide hæmoglobin complex lies parallel to the hæm plane. One might have expected it to be at a small angle to this plane.

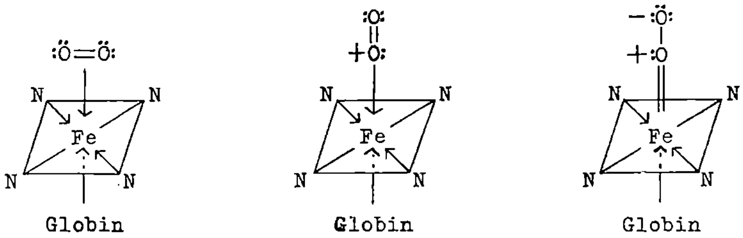

Fig. 2

Special interest attaches to the preparation of stable oxygen-carrying iron complexes as models. Thus, recently, the oxygen-carrying properties of the imidazole complexes of proto- and meso-hæm, and of ferrous dimethyl-glyoxime, have been studied by Corwin[15] and Williams[16] respectively. The imidazole complexes combine reversibly with oxygen in the solid state and when dissolved in pyridine : ferrous dimethylglyoxime show this property only in solution in the presence of bases, for example, imidazole ; in neither case have crystalline oxygenated compounds been reported.

Artificial oxygen carriers appear to be restricted to the compounds of cobalt and iron. (It is reported, however, that the μ-oxochlororhenate ion $(Re_2OCl_{10})^{4-}$ will combine reversibly with oxygen[18].) The cobalt compounds, except those derived from the parent compound *B*, suffer from the disadvantage, as model compounds, that the reversibly combined oxygen molecule is believed to form a bridge between the cobalt atoms in two adjacent molecules ; in effect,

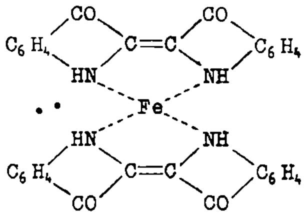

Fig. 3

one oxygen atom is reversibly held by each cobalt atom. The few oxygen-carrying chelates which contain iron have been reported to combine with one or two[16] oxygen molecules for each iron atom.

The iron-*bis*-indigo complex was first prepared by Kunz[7] and Kress[17], who claimed they had isolated the unoxygenated and oxygenated compounds in crystalline form. To these they gave the formulæ Fe(indigo)$_2$ and Fe(indigo)$_2$O$_2$ respectively. In addition, they found that the unoxygenated compound, which was prepared by treating an excess of iron pentacarbonyl with indigo suspended in pyridine, combined with nitric oxide and hydrogen cyanide but not with carbon monoxide. Because these workers could find no evidence for the evolution of hydrogen in the formation of the unoxygenated compound they assigned the formula shown in Fig. 3 to it and considered that the iron was united to the indigo by 'residual valencies', the apparent oxidation number of the iron atom being zero. This complex bears at least a superficial resemblance to hæmoglobin, and seemed likely to repay more detailed investigation.

The iron–indigo complex has been prepared by the method used by Kunz and its empirical formula confirmed. Its magnetic susceptibility has been measured by the Gouy method over the temperature-range 100–300° K. (Fig. 4). It behaves as a normal paramagnetic compound with $\theta = -25°$ K. and its magnetic moment is 5·4 B.M., corresponding to that of ferrous iron in a spin-free complex. For the molecule to be square planar, using $3d\ 4s4p^2$ hybridized orbitals, a spin-only moment of about 2·83 B.M. corresponding to 2 unpaired electrons would be expected[19]. The most likely structures, therefore, are a tetrahedral monomer or an octahedral polymer involving co-ordination to oxygen or nitrogen atoms of other molecules. The low solubility of the compound suggests the latter, but polymers might arise simply from hydrogen bonding. The susceptibilities of some impure specimens showed considerable dependence on field-strength. This is believed to be due to the absorption of traces of iron pentacarbonyl, which decompose into iron and carbon monoxide on drying. These impurities were eliminated by careful preparation. The compound is a yellow-brown crystalline solid which very rapidly becomes dark green upon exposure to oxygen. This colour change is not reversed if the solid is left under reduced pressure. If the increase in weight upon oxidation is taken to be due to the absorption of oxygen, between 2 and 3 oxygen atoms are absorbed for each iron atom. The magnetic susceptibility decreases upon oxidation and the magnetic moment calculated from measurements at room temperature is close to 4 B.M. If we assume that the iron atom is oxidized, the fall in moment may be due to spin–spin interaction in an oxygen-bridged ferric complex, since the spin-free moment of a ferric complex is 5·92 B.M. It could also arise from the formation of a ferric complex involving the use for bonding of one inner *d* orbital (for example, dsp^2 or dsp^3 hybridization) for which three unpaired electrons are expected (3·88 B.M.). Some susceptibility measurements have been made over a temperature-range with the oxidized compound, but these are difficult to interpret because ferromagnetic impurities are produced during oxidation.

The iron atom in iron pentacarbonyl is zero valent. To account for the production of a ferrous compound it must be assumed either that one of the indigo molecules is reduced during co-ordination with the iron atom or that hydrogen gas is evolved in the reaction. It has been confirmed that no hydrogen is evolved, and the action of methyl magnesium iodide on the unoxygenated compound has shown that it contains 4 active hydrogen atoms, that is, there is no net displacement of hydrogen atoms from the indigo molecules on co-ordination. Infra-red spectra of the unoxygenated compound show absorption bands which, from comparison with the spectra of indigo and indigo white, can be assigned to OH stretching vibrations. These disappear on oxidation, and new absorption bands appear in the carbonyl stretching region. The complex is decomposed by water and acids, but is soluble in hot, concentrated alkali. Its solubility in alkali suggests the presence of hydroxyl groups, as does its slight conductivity in pyridine. These observations indicate that one of the indigo molecules is present in a reduced form analogous to indigo white.

Kunz and Kress reported that when a solution of the complex in pyridine was exposed to oxygen the colour changed from red to green and one oxygen molecule was absorbed for each iron atom. If the pressure over the solution was reduced, or the green solution was allowed to stand under nitrogen, gas was evolved, the red colour being rapidly restored; more oxygen could then be absorbed. This process could be repeated several times until finally the compound was oxidized. This has been confirmed. However, their experiments were carried out in

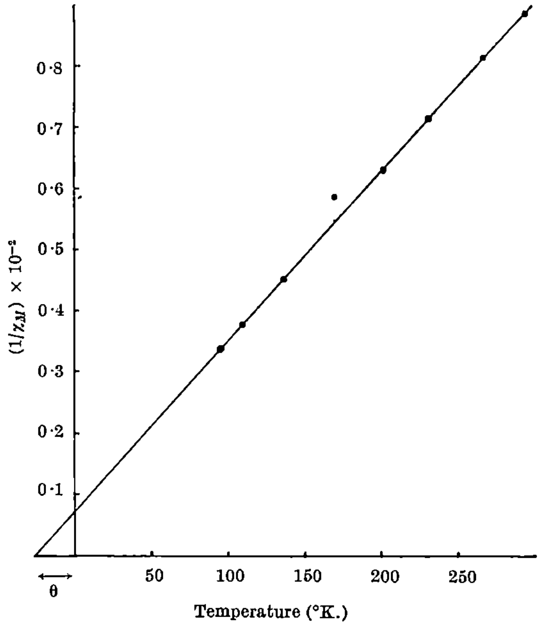

Fig. 4

solutions containing the excess of iron pentacarbonyl used in the preparation of the indigo complex, and the gas evolved could have been carbon monoxide produced as the residual pentacarbonyl reduced the green compound. In our experiments the gas evolved under reduced pressure from the oxygenated solution has been collected at atmospheric pressure by means of a Toepler pump and found to contain carbon monoxide together with all the oxygen previously absorbed. These experiments have been repeated in the absence of iron pentacarbonyl. Oxygen then produced the same colour change, and, although approximately 1 molecule of oxygen was rapidly taken up for each iron atom, much further oxidation soon occurred and the green solution became brown. The oxidation can be stopped at the green stage by pumping off the oxygen above the solution. When the green solution was allowed to stand under reduced pressure for several hours it became lighter in colour, but never the original red, and no oxygen could be detected in the small amount of gas evolved. Thus, the combination with oxygen is not reversible in the absence of iron pentacarbonyl.

When iron pentacarbonyl, or reducing agents such as hydrazine or sodium dithionite together with a little sodium hydroxide, were added to the green oxidized solution, the red colour was restored. It has been found that a ferrous salt, in pyridine, will give a green solution as soon as indigo is added; and the solution becomes red when reducing agents are added. On exposure to the air the solution becomes green, and these changes can be reversed until all the reducing agent is expended. The compound responsible for these changes has not been isolated, but it is probably identical with that prepared from iron pentacarbonyl.

The green oxygenated compound has been isolated from solution in pyridine, and from its analysis and infra-red spectrum is similar to the solid oxidation product. It also has a low magnetic moment, approximately 4 B.M., similar to that of the oxidized solid compound. It is not readily obtained because it is easily oxidized in pyridine. When it is dried under reduced pressure at varying temperatures it slowly loses weight, presumably because a slow reaction is occurring. Consequently, it is difficult to obtain an accurate analysis for the compound. The formula $\mathrm{Fe(indigo)_2O_2}$ assigned by the previous workers appears to have been based on an incomplete analysis. The substance is not suitable for X-ray measurements.

The unoxygenated compound reacts with nitric oxide or hydrogen cyanide. In solution in pyridine it was found to absorb 5 molecules of nitric oxide for each iron atom and in the process indigo was liberated. Since no protons were introduced in the reaction this established that no hydrogen atoms are removed from the indigo molecules on co-ordination. When hydrogen cyanide reacted with the unoxygenated compound dissolved in pyridine a yellow, crystalline compound was precipitated. Upon exposure to oxygen this compound rapidly became green. It is believed to have the formula $\mathrm{Fe(indigo)_2(CN)_2}$, but its investigation is not complete.

The co-ordination of an indigo molecule as a bidentate ligand can take place through 2 nitrogen atoms, 2 oxygen atoms, or a nitrogen and an oxygen atom. When two molecules are co-ordinated there are several possible formulæ, and if, in addition, one indigo molecule is assumed to be reduced, at least nine possible formulæ can be suggested. There can also be many different arrangements of the 4 hydrogen atoms in each molecule. A structure involving minimum re-arrangement, which is at least consistent with the infra-red spectra, is shown in Fig. 5; however, this would involve appreciable distortion of the bond angles. Structures in which the iron atom is co-ordinated to one oxygen and one nitrogen atom of the indigo residue are also feasible.

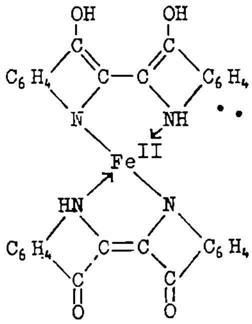

Fig. 5

In such a complicated molecule it is difficult to distinguish between the many possible formulæ without studying the infra-red spectra of many related compounds. We are now extending our studies to the indigo complexes of other metals in order to establish the structure of these compounds.

The oxidation of this complex, whether in the solid state or in solution, is undoubtedly a complicated process. Part of the reaction with oxygen must be oxidation of the iron atom to the ferric state, and part the oxidation of the chelate.

This work has shown that ferrous-*bis*-indigo is not capable of reversible combination with oxygen, and thus, as a model for hæmoglobin, is unsuccessful; and it illustrates the danger, in complicated molecules containing both metals and large organic ligands, of ascribing the reactions of the molecule to the metal atom without a complete knowledge of the structure of the molecule.

Our thanks are due to Dr. A. Earnshaw for making the magnetic susceptibility measurements; and to the Medical Research Council for a fellowship (L. F. L.).

Fusion Curve of Iron to 96,000 Atmospheres: Temperature of the Earth's Core

A NUMBER of arguments have been advanced[1] tending to show that the boundary of the Earth's core is molten iron, and the central part of the core is solid iron. If the Earth's core is composed of iron the solid phase of which near the melting point is the same as that at the surface, then a determination of the melting point of iron at about $1 \cdot 4 \times 10^6$ atmospheres (the pressure at the boundary between the mantle and the liquid core) would set a minimum temperature for this depth within the Earth.

No such pressures are available for static tests at the surface. For the present, it is necessary to be content with an extrapolation of the melting point to one or two million atmospheres. Recently, Simon and Gilvarry (see ref. 2) have published communications giving extrapolations of the melting point of iron to a few million atmospheres, using the results of experimental work on the initial slope of the fusion curve and certain theoretical deductions on its probable course[3].

Simon's and Gilvarry's extrapolations were extended over a pressure-range of six orders of magnitude in order to reach the pressure of the core boundary. We have now determined the melting point of iron experimentally to 96,000 atmospheres, so that the extrapolation is reduced to one order of magnitude in pressure. A brief summary of these results is presented here. A detailed account of the work on the melting point of iron, including a description of the structure of the sample and the method of measuring temperature and pressure, will appear elsewhere[4]. The apparatus used was the same as that used for the synthesis of diamond[5].

At a pressure of 96,000 atmospheres, the melting point of iron was found to be 1,740 ± 15° C. The error in pressure determination was estimated to be ±10 per cent. The fusion curve followed a smooth course over the entire pressure-range from 1 to 96,000 atm. with no indication of the existence of a triple point between γ, δ and liquid iron in the pressure-range covered. The lowest pressure at which a melting point was obtained was about 10,000 atm.

Simon's fusion equation (see ref. 3):

$$\frac{P}{a} = \left(\frac{T}{T_0}\right)^c - 1$$

fitted the experimental results with the constants $a = 75{,}000$ atm. and $c = 8$, and it was used to extrapolate the fusion curve to $1 \cdot 4 \times 10^6$ atm. pressure. In this equation, P is the pressure in atmospheres, T_0 the melting temperature in degrees absolute at the origin of the fusion curve at one atmosphere pressure, and T the melting temperature at pressure P. The extrapolated curve gave 2,340 ± 50° C. for the melting temperature at $1 \cdot 4 \times 10^6$ atm. Allowing for the effect of dissolved foreign atoms on the melting point and a drift of the extrapolation away from the true curve, the melting point at the boundary of the Earth's core should lie in the range 2,340 ± 200° C.

Simon (see ref. 2) used for a and c the values 150,000 atm. and 4 respectively, obtaining for the melting temperature of iron at the core boundary about 3,000° C. Gilvarry's[4] values for a and c were 347,000 atm. and $1 \cdot 9$, giving about 3,900° C. for the melting temperature at the core boundary.

During the course of the melting-point determinations, it was convenient to observe the β–γ transformation by the sharp change in slope of the electrical resistance–temperature curve which accompanies this transformation. At 76,000 atm. the transformation temperature had decreased to 705 ± 15° C. The initial slope of this curve was in the range $-8°$ to $-10°/1{,}000$ atm.

The parts of the phase diagram for iron determined from these experiments is illustrated in Fig. 1.

The iron used in these experiments was 99·94 weight per cent iron. The foreign atoms present included 0·0023 weight per cent oxygen, 0·002 carbon and 0·004 nitrogen. The largest single other impurity was 0·02 per cent nickel, the influence of which on the melting point was negligible.

I wish to thank Warren Moore and J. Schermerhorn of this Laboratory for the specimens of iron, Sherman

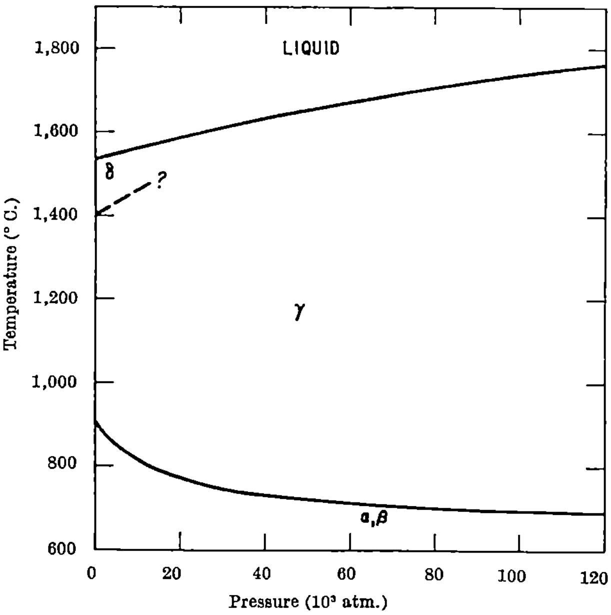

Fig. 1. Phase diagram for iron. The experimental results on the melting point were extended to 96,000 atm. and on the β–γ transition to 76,000 atm.

Reed and Wilson Weir for their excellent workmanship in constructing the test samples, and Roy E. Tuft for his valuable assistance in conducting the experiments.

Sporadic *E*-Region Ionization, 'Spread F', and the Twinkling of Radio Stars

All these phenomena reveal the presence in the ionosphere of inhomogeneities in electron density of thickness some kilometres or less, the frequency of occurrence of which shows well-marked diurnal, seasonal, and geographical distributions, as well as correlation with geomagnetic activity. In the auroral zones they may be mainly due to ionization (in columns and sheets) produced by direct bombardment of the particles producing auroræ. However, auroræ occur rarely at moderate or low latitudes, where all these phenomena happen daily; in fact, at such latitudes the correlation of the latter with magnetic activity tends to be rather strongly negative.

A clue to the origin of these phenomena at non-auroral latitudes may lie in the fact that they appear to have one common feature: they occur most frequently or most intensely at times when the ionization of the relevant matrix region (*E* or *F*) is moving *upwards* under the influence of the electrodynamic forces associated with the ionospheric electric current systems responsible for the solar, lunar or disturbance geomagnetic variations. For example, equatorial sporadic *E*-region ionization is a maximum near noon, when the equatorial electrojet current is a maximum eastwards, and at 8–9 hr. lunar time[1], when the lunar electrojet has a similar maximum. Again, the occasional reductions of the equatorial day-time (eastward) electrojet which are associated with geomagnetic disturbance are accompanied by a corresponding reduction[2] in equatorial sporadic *E*-region ionization.

Some years ago it was suggested[1] that such *E*-region ionization was essentially due to vertical movements, and the phenomena associated with the drifting of an inhomogeneity in an otherwise uniformly ionized medium were afterwards examined[3]. In a region of negligible Hall conductivity (such as the *F*2-region) the effects are simple. A long cylinder of electron density $N + \Delta N$ aligned along the magnetic field H, and embedded in a medium of electron density N drifting perpendicularly to H with velocity V, drifts relatively to the matrix medium with the velocity:

$$v = -V\varepsilon/(2 + \varepsilon) \qquad (1)$$

where $\varepsilon = \Delta N/N$ and may have any numerical value. (It is easy to show also that a sphere of corresponding density drifts with the velocity $v = -V\varepsilon/(3 + \varepsilon)$.) In both cases the motion is simple; there is no distortion of the cylinder or sphere, which moves like a solid through the medium without interchange of ionization at its surface.

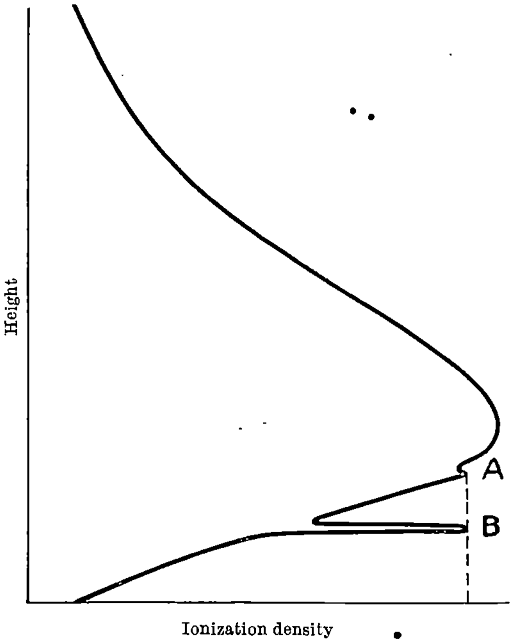

Fig. 1. Illustration of how a small positive perturbation of ionization density at *A* on the under surface of an upward drifting region becomes a large positive perturbation at *B* because it drifts upwards more slowly than the main body of the region

These results have been applied recently[4] to explain the occurrence of 'spread *F*', and the scintillation of radio stars. It has been shown that the ionization on the under-surface of the *F*-region is kinematically unstable when the region is drifting *upwards*. At such times a small irregularity (*A* in Fig. 1) drifts downwards relatively to the region and becomes a large irregularity (as at *B*) capable of producing the pronounced scattering responsible for scintillations and 'spread *F*'. It has been shown[4] that the magnitude of the inhomogeneities thus produced seems quantitatively adequate, while the times at which these phenomena should occur agree well with the known morphology of the occurrence.

At first sight it might appear that these simple considerations could also be applied directly to explain the formation of sporadic *E*-region ionization. Here, however, a difficulty appears. For the phenomenon depicted in Fig. 1 to occur it is essential that the life (relaxation-time) of the ionization in the irregularity be substantially longer than the time required to drift from *A* to *B*. This condition is adequately satisfied in the *F*-region, where the relaxation-time of the (night-time) ionization is about 2 hr.; it is certainly not satisfied in the (day-time) *E*-region, where the relaxation-time is only 3 or 4 min.

The difficulty disappears when the Hall conductivity of the *E*-region is taken into consideration. In such a medium it has been shown[3] that movement of a cylinder like a solid body is impossible. However, movement of a cylindrical perturbation of N is possible[5] in such a way that there is constant interchange of ionization between the cylinder and the medium at the surface of the cylinder. In other words, a cylindrical perturbation of ionization travels through the medium as a kinematic wave. For such a wave to be propagated from A to B and so produce a major inhomogeneity it is not necessary for the time of travel to be less than the relaxation-time of the medium ; it suffices if the wave travels a distance comparable with the radius of the cylinder in a time less than the relaxation-time. This condition is frequently satisfied in the E-region of the ionosphere for cylinders of less than about 1 km. diameter.

It can readily be shown that the velocity of the wave relative to that of the moving medium, and in the direction of the latter motion, is :

$$v = -\frac{V\varepsilon(2+\varepsilon)}{4(1+\varepsilon)\cos^2(\alpha-\beta)+\varepsilon^2} \qquad (2)$$

where tan α,β are ω_e/ν_e, ω_i/ν_i respectively, $\omega_{e,i}$ being the gyro frequencies and $\nu_{e,i}$ the collisional frequencies of the electrons and ions.

There is also a component of the wave velocity perpendicular to V, but in the ionosphere this cannot of itself lead to the generation of substantial inhomogeneities as it is mainly horizontal.

It will be noted that at heights of about 100 km., where cos $(\alpha-\beta)$ is about 1/20, $|v|$ may be up to five times $|V|$: the wave of inhomogeneity travels up to five times faster than the general drift of the medium. It seems almost certain that these waves are responsible for the production of equatorial sporadic E-region ionization, which appears at the times of solar, lunar and magnetic disturbances when the drift motion in the E-region is upwards and the wave motion consequently downwards for ε positive, thus leading to pronounced irregularities on the under-surface of the region. (For ε negative the wave motion is, of course, upwards, small deficiencies in N in the lower part of the region being transferred upwards to appear as substantial 'holes' near the ionization peak.) The recent discovery[6] that irregularities in sporadic E-region ionization at the magnetic equator are aligned horizontally along the geomagnetic field is also in accord with this finding. It also seems likely that these waves are responsible for much of the sporadic E-region ionization found in moderate latitudes. Their importance in auroral latitudes can be assessed only after further studies.

It is remarkable that the same basic fact, kinematic instability in the ionization gradient of a medium drifting across a magnetic field, should appear to be responsible for three geophysical phenomena, namely, scintillation of radio stars, spread F, and at least some forms of sporadic E-region ionization. However, no new concept is involved ; the relevant conclusions follow from the application of well-established electrodynamical principles to known ionospheric facts. The only approximation assumed is that the radius of the perturbation should be much less than the scale-height of the ionized region, a condition which seems safely satisfied in both regions E and F. Indeed, if these phenomena did not occur in the relevant parts of the ionosphere, it would seem to be necessary to explain why they were absent at the times and places where the ionization is known to have appropriate upward drift.

A Type of Variation of the Signal Strength from 1958 δ2 (*Sputnik* 3)

This communication is based on observations of the *Sputnik* 3 signal strength carried out from the end of November 1958 at Kiruna Geophysical Observatory, Sweden (67·8° N., 20·4° E.). The 20·005 Mc./s. signals were received on a standard communications receiver (Collins 51 J–4) and recorded on a mV.-pen recorder with a full-scale deflexion time of approximately 1 sec. The receiver was connected to a fixed 'quad' 20 Mc./s. antenna with a very low directivity.

From the results (of about 200 recorded passings of *Sputnik* 3) it is possible to see that part of the sudden fluctuations of signal strength (superimposed on the regular Faraday pattern and rotational fading) seems to be connected with definite points of the orbit. Over a period of a few days they occur at an almost constant time, measured from the time of equatorial crossing, as the continuous change in time is very slow. These times agree well with the moments when the satellite is passing below or above its track from one or more revolutions before. Sudden drops of signal strength coincide with passages above earlier tracks, and enhancements with passages below. *Sputnik* 3 passes above the paths of the first to the fourth previous revolutions, and below those of the ninth to the thirteenth previous revolutions (900–1,400 min. before). These facts indicate that the satellite produces heavily ionized tracks of a very long lifetime. To test this hypothesis, 85 night-passages (with very good reception of satellite signal

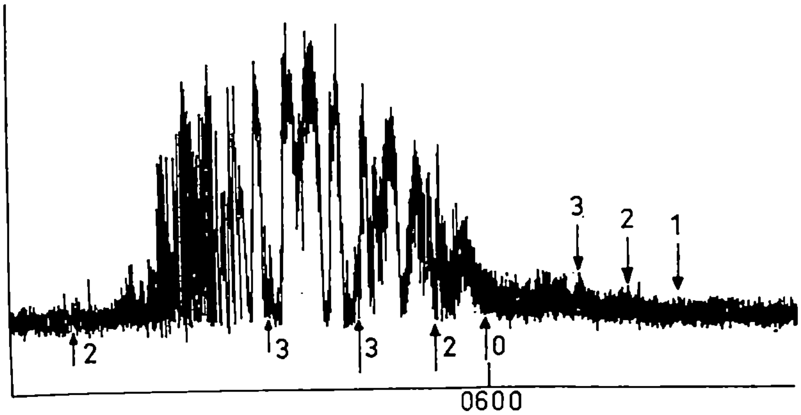

Fig. 1. A typical signal strength record (revolution number 3486) with arrows indicating predicted times of observed enhancements and drops and attributed weights w

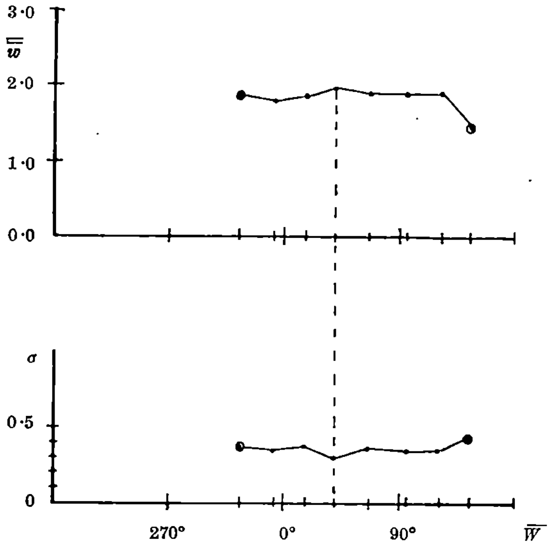

Fig. 2. The second mean weights, $\bar{\bar{w}}$, of the $\bar{w}$'s and the mean square deviations from $\bar{\bar{w}}$, σ, versus the mean longitude of equatorial crossings $\bar{W}$

and absence of interferences) during January 7–25, 1959, were investigated in the following way: the times at which one revolution crossed earlier ones were calculated approximately on the basis of the space-track bulletins[1]. If the predicted passage above a track coincided with a sudden decrease of signal strength, the 'crossing' was given a weight, w, from 1 to 3 (both time coincidence and the amplitude of the minimum were taken into account) and the weight $w = 0$ was attributed to the crossing if there was no decrease in signal strength. The corresponding procedure was used with passages below the tracks. A typical signal strength record with arrows indicating predicted times and attributed weights, w, is shown in Fig. 1. For every satellite passage the mean weight, $\bar{w}$, was calculated.

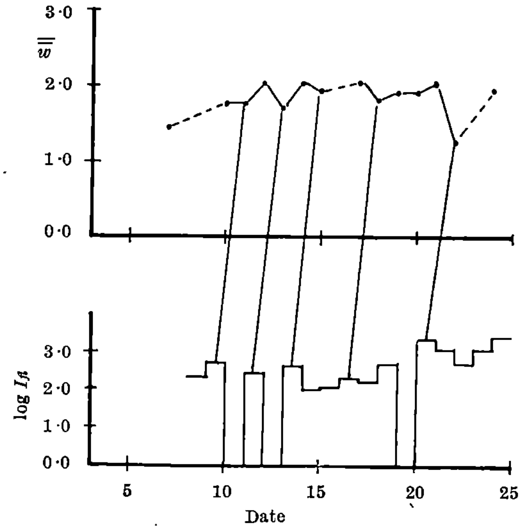

Fig. 3. The second mean weights, $\bar{\bar{w}}'$ (calculated for each night, irrespective of the longitude of equatorial crossings), and the logarithm of the High Altitude Observatory, Boulder, total flare activity index, I_{fl}, versus time

It is to be expected that $\bar{w}$ will depend on the geometrical configuration of the path of the satellite, with respect to the ionized track and the position of the observer, and also on the conditions in the ionosphere. The effect of geometrical configuration was investigated by grouping passages with respect to the longitude of equatorial crossing, W. For every group of passages the second mean weight, $\bar{\bar{w}}$, of the $\bar{w}$'s, was calculated, together with the mean square deviation from $\bar{\bar{w}}$. The result is plotted in Fig. 2. It can be seen that the highest value, $\bar{\bar{w}} = 1·95$, and the smallest dispersion of $\bar{w}$ is obtained for the group of passages with a longitude of equatorial crossing of about 44° W., that is, for passages nearest to Kiruna. It is evident that the time of crossing in a vertical plane and the time at which the radiation from the satellite traverses the earlier track should agree best for that group.

It is possible to see the influence of ionospheric conditions from seasonal changes of the second mean weight $\bar{\bar{w}}'$ calculated for each night (average of $\bar{w}$ for all passages during one night, irrespective of the longitude of equatorial crossings) (Fig. 3). The lower diagram of Fig. 3 represents the logarithm of the High Altitude Observatory, Boulder, total flare activity index, I_{fl}, versus time. Each decrease in $\bar{\bar{w}}'$ seems to be connected with an enhancement of solar activity, displaced in time about one day, as is to be expected.

The height of satellite 1958 δ 2 was always greater than 700 km. in the region of reception. The phenomenon is being studied in more detail.

I am greatly indebted to Dr. B. Hultqvist for valuable discussions. The work on which this communication is based has been supported by the European Office of Air Research and Development Command (Contract 61(514)–1314).

The Twilight Radiation at 6708 A.

Recently, Delannoy and Weill[1] have reported a new atomic emission line in the spectrum of the twilight sky at Terre Adelie. The wave-length of the radiation is given as 6708 ± 1·5 A., and the authors suggest that the line may be the resonance line of lithium at 6707·8 A. The observation is confirmed, and the same identification proposed, by Gadsden and Salmon[2] (New Zealand and Antarctica). On the assumption that the identification is correct and that the lithium and sodium atoms are distributed in the same manner in the atmosphere, Barbier *et al.*[3] have computed the ratio of the concentration of lithium to sodium from the line intensities. They arrive at a ratio which agrees with the ratio found for the metals in meteorites.

The discovery of the new radiation was brought to my attention by Profs. Rosseland and Harang (Astrophysical Institute, University of Oslo) in January this year, and a search for the line was at once started at Aas, Norway (59° 40′ N., 10° 47′ E.). The instrument used was a grating spectrograph with a Bausch and Lomb plane grating, 102 mm. × 128 mm.,

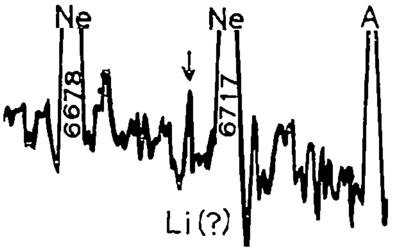

Fig. 1. Photometer tracing of a twilight spectrogram from January 23 (1735–50 M.E.T.). Lithium line indicated by arrow

600 lines/mm., blaze wave-length 1·6μ, and a camera objective from the Wray Optical Works, *f*/0·71, focal length 64 mm. The linear dispersions in the second and third orders are about 80 and 50 A./mm. respectively. (For a fuller description of the instrument see ref. 4.)

A series of twilight spectra, obtained on January 18 (Kodak 103 *aF* plate) in the third-order spectrum, showed a very sharp but faint line in the correct place. Later, the line was obtained in both the second- and the third-order spectra, showing that it really belongs to the red region.

Fig. 1 is a cutting of a photometer curve of one of the spectrograms, with a comparison spectrum superimposed (the neon lamp used contained traces of helium and argon). The line, supposed to be due to lithium, is indicated by an arrow. It is the only line in this region which extends across the spectrum and is therefore easily separable from the lines of similar intensity in the comparison spectrum (helium fourth order, neon and argon, not indicated in Fig. 1). Wave-length measurements from several spectra have given the mean value 6707·7 ± 0·5 A., which is very close to the value of the lithium resonance line. The proposed identification seems very plausible.

The line has been observed in both morning and evening twilight. Spectral series have been taken with the collimator of the spectrograph elevated 4·5° and 9·5°. The line appeared when the depression of the sun below the horizon was less than about 14·5° and 13° respectively. This is very nearly the same solar depression limits as those observed for the sodium *D*-line enhancement in twilight[5]. The lithium and sodium radiation thus probably originate from the same atmospheric level. (A difference of, say, 5 km. in the screening height of the lower atmosphere for the solar light responsible for the resonance excitation of the lithium and sodium atoms will result in a difference of about 3 km. in the heights of the two layers. This difference is certainly too small to be detectable except when the line intensities of the spectral series, and the azimuth and elevation angles of the collimator of the spectrograph, are measured with the utmost precision[6].)

Gadsden and Salmon[2] have reported a decrease of the lithium layer relative to the sodium layer of about 0·4 km. per day between August 13 and September 5, 1958. The results from Norway, collected from January 18 to February 20, 1959, indicate no such decrease of the lithium layer. In view of what is said parenthetically above it seems difficult without further evidence to accept the reported small decrease of the lithium layer, the more so as the authors themselves state that the Hallet spectra have not yet been available for precise measurements.

In a recent communication, Barber[7] suggests that the lithium atoms originate from atomic bombs, detonated in the central Pacific Ocean. His argument is based mainly on the observations of Gadsden and Salmon of the sudden (?) appearance of the lithium line on August 5 (a nuclear detonation occurred on August 1); the intensity ratio of the lithium and sodium lines, estimated to be about unity at Hallet; and the differential decrease of the lithium layer.

The latter observation seems doubtful. So does its explanation as an association of the lithium atoms with falling meteoritic dust or smoke particles from bomb explosions. It is not easy to understand why the free lithium atom, emitting the resonance radiation in the twilight, should not remain a free atmospheric constituent unaffected by dust and particles. A temporary or local high intensity of the line is, on the other hand, not a surprising observation in view of the great fluctuations of other airglow radiations[8]. The argument is therefore not completely convincing even if it is by no means improbable.

I am inclined to believe that more than one source are responsible for the metal content of the atmosphere. Evaporating meteorites, and to a small extent disintegration of atmospheric atoms by cosmic radiation, are probably permanent sources. Volcanic eruptions and nuclear bomb explosions may occasionally increase the concentration appreciably.

It has been stated that if meteorites are a major contributor, then other metals such as potassium and calcium should give observable radiations in the airglow. Calcium-ion radiation has been observed[9]. As for potassium, the detection of the resonance doublet at 7665 A. and 7699 A. is made extremely difficult by the great absorption of the oxygen (0,0) atmospheric band in that region. Some twilight spectrograms, taken with the grating spectrograph at Aas, have shown distinct increases of the 'background' radiation between the rotational absorption lines of the (0,0) band at the wave-lengths mentioned. I hesitate to state positively that this is the potassium doublet. Further observations are needed. Unfortunately a prolonged spell of bad weather has lately hindered observations.

CRYSTALLOGRAPHY

Crystal Symmetry of Struvite (Guanite)

We have examined a small cluster of white crystals which were discovered in a can of Japanese crabmeat by Prof. H. E. Petch, McMaster University, Hamilton, Ontario. Spectrographic analysis showed

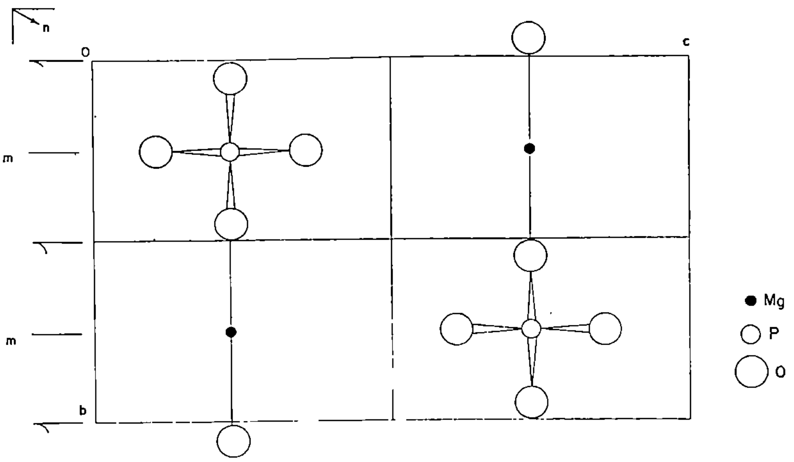

Fig. 1. Suggested partial structure of struvite projected on to the *bc* plane

that the crystals contained both phosphorus and magnesium, and the density, determined by flotation in a heavy liquid, was found to be 1·71 gm. cm.$^{-3}$. The crystals were insoluble in water. The unit cell and systematic absences of X-ray reflexions were determined from a small single crystal using a Buerger precession camera. They are: a_0 = 6·13 ± 0·02 A., b_0 = 6·92 ± 0·02 A., c_0 = 11·19 ± 0·02 A., $a_0 : b_0 : c_0$ = 0·883 : 1 : 1·616, *hkl* no absences, *hk*0 no absences, 0*kl* $k+l = 2n+1$ absent, *h*0*l* no absences, *h*00 no absences, 0*k*0 $k = 2n+1$ absent, 00*l* $l = 2n+1$ absent. The space group is $Pnm2_1$ and the a_0 axis has pseudo-hexagonal symmetry.

The crystal has been identified as struvite (or guanite), which Dana[1] describes with a chemical composition $Mg(NH_4)PO_4.6H_2O$, point group *mm*2 and axial ratios 0·8827 : 1 : 1·6102. The corresponding unit cell obtained from X-ray measurements is stated to be a_0 = 6·09 kX., b_0 = 6·97 kX., c_0 = 11·18 kX., which is in reasonable agreement with the cell obtained by us. The space group given by Dana[1] is *Pmc*2, which is not consistent with the systematic absences reported above. Instead, when our observations are combined with the morphological symmetry, they indicate unambiguously the non-centrosymmetrical space group $Pnm2_1$. Finally, Mellor[2] reports that struvite has a density of 1·715 gm. cm.$^{-3}$ and has a very low solubility in water.

With this information, some of the features of the atomic structure of struvite may be predicted. The density calculated on the basis of a cell content $Mg_2(NH_4)_2(PO_4)_2.12H_2O$ is 1·72 gm. cm.$^{-3}$, which is very close to the observed value. Since, in the space-group $Pnm2_1$, the general positions are four-fold and the special positions on mirror planes are two-fold, it follows that the magnesium and phosphorus atoms and the (NH_4) group must all lie on mirror planes perpendicular to the b_0-axis. It is expected that each phosphorus atom will be at the centre of an oxygen tetrahedron so that four of the oxygen atoms will lie on two sets of special positions and four more oxygen atoms will be in general positions approximately 1·3 A. from the mirror planes in the *y*-direction. A possible arrangement of these atoms is shown in Fig. 1 projected on the *bc*-plane. If the magnesium atom has the same *x*-co-ordinate as the oxygen atom in the general position, then there will be a chain of atoms, O—O—Mg—O, in the *y*-direction with normal bond-lengths O—O = 2·8 A. and Mg—O = 2·05 A. and with a repeat length 6·9 A.; this is the observed length of the b_0 axis. If we are correct in supposing that the oxygen tetrahedra have the orientation shown in Fig. 1, then a suitable position for the NH_4 group would be directly above the phosphorus atom. The nitrogen atom would then be tetrahedrally bonded to four oxygen atoms such that $O—NH_4$ = 2·5 A. It is not possible to place the twelve remaining oxygen atoms with certainty, but it is reasonable to expect that the magnesium atom will be octahedrally co-ordinated by oxygen atoms or water molecules as in $MgHPO_3.6H_2O$ (Corbridge[3]).

Some support for this structure is provided by a Patterson projection on the *bc* plane given in Fig. 2. This was computed with rough intensities obtained from a precession picture, using reflexions obtained with molybdenum *K*α radiation with $\sin \theta/\lambda \leqslant 0·55$. It is thought that peak *A* is produced by Mg—P vectors and peak *B* by Mg—O and P—O vectors. The remaining peaks cannot be accounted for without speculating on the other oxygen positions. No detailed comparison of F_0 and F_c was made but it was observed that the proposed atomic positions are consistent with large observed intensities from the planes 040, 004 and 048.

Struvite has been found previously in canned fish: Palache[4] reports the discovery of this substance in canned shrimp and Ayres[5] describes its occurrence in canned lobster. Both writers suggest that the presence of ammonia indicates that the crystals are produced by bacterial fermentation. Other remarkable occurrences of struvite are mentioned by Dana[1]: it was first found in Nature in a bed of peat under an old church in Hamburg, Germany, and was found in bat guano from the Skipton Caves, Victoria, Australia, and with newberyite in the tooth of a mammoth from Quartz Creek, Dawson, Yukon. In all these instances it appears that the compound was the result of decomposition of organic matter.

It should be noted that Mellor[2] states that large crystals of struvite can be readily prepared in the

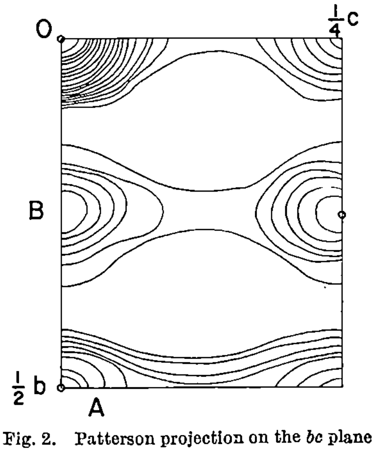

Fig. 2. Patterson projection on the *bc* plane

laboratory. Since the crystal lacks a centre of symmetry, is piezoelectric and has a good (001) cleavage perpendicular to the polar axis, it is likely that thin plates could be prepared for the examination of possible ferroelectric effects.

We do not plan further work on this compound.

We are grateful to Mrs. B. Murray for her help in obtaining the X-ray photographs.

Absolute Measurement of the Intensity of the (111) Reflexion for Diamond

Atomic scattering factors of carbon atoms in the valence state, as computed by McWeeney[1], are in close agreement with the values obtained on the basis of measurements on diamond[2]. An exception occurs only in the f_C-value of (111), which was found to be 3·299, while McWeeney's theoretical value is close to 3·100.

To clear up this discrepancy, a careful re-determination of the absolute intensity of the (111) reflexion of diamond has been made. To avoid extinction effects, the measurements were carried out on a fine and pure diamond powder of particle size about 0·5μ. Particles of this size might still show some extinction. However, this influence on the intensity should be small and not exceed 1 per cent. The discrepancy is much larger.

The intensity was measured by two different techniques, surface reflexion and transmission. A Geiger proportional counter was used ('Norelco') and crystal monochromatized radiation. To avoid λ/2 in the monochromatized beam, voltages not higher than 14 kV. were applied to generate the copper *K*-radiation.

Table 1 contains the results.

Table 1

Method	Operation of X-ray tube		$1/8\ F_{111}$
	kV.	m.amp.	
Reflexion	14	20	2·211
,,	10	20	2·212
,,	14	20	2·222
,,	12	20	2·037
,,	14	18	2·166
,,	14	18	2·168
,,	14	18	2·104
Transmission	14	18	2·295
,,	14	18	2·206
,,	14	18	2·256

The mean value of these measurements was taken in two different ways, with and without weighting the accuracy of the single measurements. The weighted mean is $1/8\ F_{111} = 2{\cdot}20 \pm 0{\cdot}07$, $f_C = 3{\cdot}11 \pm 0{\cdot}10$, whereas the unweighted mean is $1/8\ F_{111} = 2{\cdot}18_8 \pm 0{\cdot}07$, $f_C = 3{\cdot}09 \pm 0{\cdot}10$. Both these values agree with the figure calculated by McWeeney within the limit of error.

METALLURGY

Structure of Scale on Plain Carbon Steels

The classical picture of high-temperature scales on plain carbon steels as determined by Pfeil[1] shows a three-layered structure. An outer layer of hæmatite, Fe_2O_3, a middle one of magnetite, Fe_3O_4, and an inner one of wüstite, FeO, next to the parent metal is the normal composition of this layered structure in a scale that is continuous with the parent metal. (For practical and historical reasons, wüstite is normally given as the stoichiometric FeO when in fact it is more accurately described as $Fe_{1-Y}O$, where *Y* is the concentration of vacancies.) Similarly, Paidassi[2], in his recent work on the kinetics of oxidation of pure irons between 700° and 1,250° C., found that the three-layered structure is present on continuous scales. However, 15 min. was the minimim oxidizing time for the lower-temperature scales that he reported.

It is known that the simple layered structures of plain carbon steel scales are modified in practice by the production of pores and blisters. After a short initial period of oxidation, these defects occur rather readily. Furthermore, in the laboratory the production of continuous scales by extensive oxidation requires elaborate surface preparation including high-temperature anneals in hydrogen to produce a clean surface prior to the oxidation experiment.

It has been assumed generally that the structure of the thin scales on the products of the modern continuous rod and strip mills conformed to the classical picture of scale structure. However, during the microscopic examination of the scales of these products, unusual types of structure were observed. Fig. 1 illustrates one type of structure first noticed on samples of wire rod. It was considered rather unusual at the time. However, in the examination of narrow hot strip samples extensive regions of this type of structure were observed (Fig. 2). It has been given the description of a 'sandwich' structure. There is almost no evidence of blistering and it is essentially a continuous scale with the parent metal.

The innermost layer in contact with the parent metal is magnetite. The middle layer is wüstite and the next layer is again magnetite. In some instances a thin outer layer of hæmatite is also observed. This unusual innermost layer of magnetite is similar in appearance to the outer primary magnetite layer when examined under the optical microscope. Its micro-hardness is also of the same order as the primary magnetite layer. When etched it appears as a single phase with sharp boundaries, and in no way resembles the dark-etching decomposed wüstite

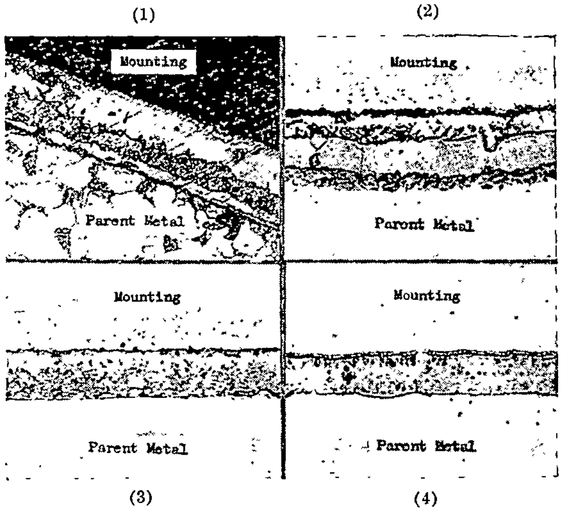

Fig. 1 (× 250) Figs. 2–4 (× 500)

illustrated in Fig. 3. This dark phase is apparently composed of fine magnetite and ferrite particles originating from the breakdown of wüstite. The boundary between the dark-etching material and the primary magnetite layer is rather indefinite when etched with a solution of citric and hydrochloric acid in methyl alcohol. The micro-hardness of this decomposed layer is similar to that of the primary magnetite.

In other structures observed on samples of wide strip mild steel, the entire scale appears to be composed of a single phase of primary magnetite. The scale towards the edges of the strip also has a thin hematite layer on top of the magnetite layer (Fig. 4).

The non-classical appearance of these structures must, of course, be associated with their origin in high-speed strip and rod mills and their thermal history after the last shaping operation, coiling and removing from the finishing line.

Whereas the decomposed wüstite phase (Fig. 3) can be readily explained by existing knowledge it is rather difficult to visualize the mechanism of the formation of the inner magnetite layer next to the parent metal. Collongues, Sifferlen and Chaudron[3] have shown that although wüstite is unstable below 570° C., its decomposition is dependent on the cooling-rate of the oxide below that temperature. They found that the kinetics of the isothermal transformation of wüstite can be expressed as an *S*-curve with the nose of the curve giving the maximum rate of transformation occurring at 480° C. Fischer, Hoffman and Shimada[4] and Fischer and Hoffman[5] have shown metallographically the breakdown of wüstite in bulk at temperatures below 570° C.

The presence of an inner layer of magnetite in the sandwich structure would be explained if it were assumed that it was originally wüstite which had decomposed below 570° C. The high concentration of oxygen next to the parent metal could be produced by either a mechanism of reverse diffusion of iron atoms back to the parent metal or by the internal oxidation of the scale at the scale–metal interface.

In those structures that show no wüstite it must then be assumed that the mechanism which produced an inner layer of magnetite was able to progress to the point where the entire wüstite layer was transformed.

Fatigue Properties of Ternary Aluminium–Zinc–Magnesium Alloys

EXPERIMENTAL work[1] has suggested that the poor fatigue properties of age-hardened aluminium alloys are due largely to the metastable nature of the dispersed precipitate. Cyclic stressing causes deformation to become progressively more localized and the precipitate in these regions may become unstable. This leads to softening which, in turn, causes a further concentration of deformation in these regions and the whole process becomes catastrophic. The mechanism by which softening occurs is uncertain, but it is thought to be associated with dislocation movements in the localized regions. It thus seems that the fatigue properties of these alloys would be improved if the stability of the dispersed precipitate could be increased or if a reduction in the mobility of dislocations in the highly stressed regions could be effected. This communication describes some initial experiments in which the second possibility is being investigated.

The mobility of dislocations may be reduced by interaction with solute atoms. Thus, in an age-hardening alloy, it would seem desirable to have present solute atoms which play no part in the ageing process and are free to participate in such interactions. A recent study of ageing phenomena in a number of ternary aluminium–zinc–magnesium alloys[2] has suggested that, when the magnesium : zinc ratio exceeds a certain value, excess magnesium atoms are present which are not required in the ageing process. This conclusion becomes more significant when it is recalled that yield-point phenomena have been observed[3] in binary aluminium–magnesium alloys, indicating that interactions can occur between magnesium atoms and dislocations. These observations suggested that a study of the effect of composition on the fatigue properties of a range of ternary aluminium–zinc–magnesium alloys might provide some interesting results.

Six alloys were selected in which the magnesium : zinc ratio was widely varied but for which the same heat-treatment cycle of solution treatment for 1½ hr. at 460° C., cold water quench, and ageing for 16 hr. at 125° C. gave approximately the same value of ultimate tensile strength[4]. By keeping these variables constant the fatigue properties could be compared with some standard of reference. Details of the actual compositions and tensile properties are given in Table 1.

Rotating cantilever fatigue specimens of 0·300 in. test diameter were prepared from forged and heat-treated bars. Standard machining techniques were used and the final surfaces of the test sections

Table 1. Alloy Compositions and Tensile Properties

Alloy	Magnesium (Mg)	Zinc (Zn)	Mg/Zn	0·1 per cent proof stress (P.S.) lb./sq. in.	Ultimate tensile strength (U.T.S.) lb./sq. in.	0·1 per cent (P.S./U.T.S.)	Elongation (per cent)
B	1·05	8·3	0·13	44,000	55,200	0·80	14·4
C	2·0	5·8	0·35	47,600	58,300	0·80	15·5
D	3·0	5·1	0·59	44,900	59,000	0·76	17·7
E	4·0	4·5	0·89	31,000	54,300	0·57	30·0
F	5·0	4·1	1·22	31,800	53,200	0·60	27·7
G	6·0	3·7	1·62	47,000	56,000	0·84	15·5

were prepared with a tungsten carbide-tipped tool.

Complete *S*—*N* curves for each alloy were not determined, but the results clearly showed that the fatigue properties vary greatly with composition (Fig. 1). Highest fatigue properties were obtained with alloys *E*, *F* and *G*, which had the largest magnesium : zinc ratios. Of these three alloys, *F* had much the best properties, and it should be noted that the magnesium : zinc ratio in this case was between those of alloys *E* and *G*. Somewhat lower properties were obtained with *C* and *D*, which had zinc and magnesium contents similar to the current commercial high-strength alloys. Alloy *B* had the lowest fatigue strength and, in view of the high zinc content, this may be due partly to grain boundary brittleness.

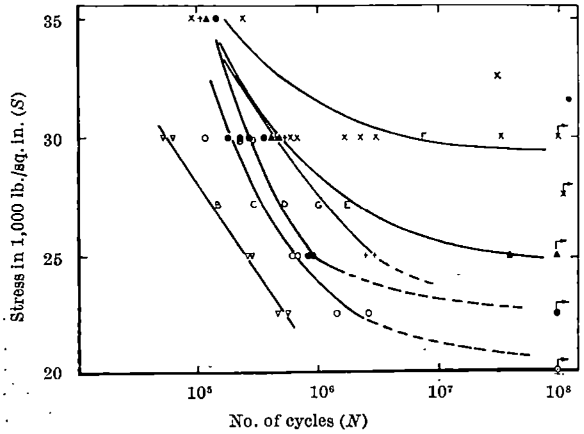

Fig. 1. Partial *S*–*N* curves for the alloys

The relationship of fatigue properties to tensile properties is also significant, since it has been proposed[5] that, in aluminium alloys, good fatigue strength is associated with low ratios of 0·1 per cent proof stress to ultimate tensile strength. Alloys *E* and *F* had 0·1 per cent proof stress values well below the values for the other alloys. However, this can only partly account for the higher fatigue properties of these two alloys since, although they had similar ratios of 0·1 per cent proof stress : ultimate tensile strength, the fatigue strength of *F* was notably better.

It thus seems likely that the high fatigue strength achieved with alloy *F* is primarily associated with a critical zinc : magnesium ratio. Whether, in fact, this is due to the interaction of excess magnesium atoms with dislocations cannot be stated. Further experimental work is in hand and this will be reported later.

Thanks are due to the Chief Scientist, Australian Defence Scientific Service, Department of Supply, for permission to publish this communication, and to Messrs. J. Y. Mann and J. M. Finney, who carried out the fatigue tests.

CHEMISTRY

Electron Affinity of Oxygen

In recent years there has been considerable argument concerning the electron affinity of oxygen[1,2], and it is the purpose of this communication to direct attention to recent developments in this field resulting from work carried out with a Lozier ionization chamber apparatus in the Department of Electrical Engineering, University of Liverpool. A full account will be published elsewhere in due course.

For many years, following the work of Lozier[3], the value of the electron affinity of oxygen was accepted as 2·2 eV., and this value has recently been reinforced by the work of Metlay and Kimball[4], who employed a flame spectroscopy method. However, work by Branscomb and Smith[5], using the elegant photo-detachment method, yielded a value of 1·45 ± 0·15 eV., later amended[6] to 1·465 ± 0·005 eV., which was incompatible with the earlier work. The situation has been further confused by the work of Schüler and Bingel[7], who obtained values of 0·98 eV. and 1·05 eV. using a spectroscopic method. Hagstrum[8] attempted to re-interpret electron impact experiments in terms of the photo-detachment value, with some success except in the case of the dissociative attachment process in oxygen. However, values in the region of 2·0 eV. have been so consistently obtained by electron impact work in oxygen as to suggest that the discrepancy is not due to any of the more obvious experimental errors which have been suggested by various workers since 1955. In a recent paper[9] reasons have been advanced for believing that these errors do not appear, at least in the work carried out at Liverpool. So it may fairly be said that, so far as electron impact experiments are concerned, the situation has remained one of unresolved confusion.

Branscomb[1] has attempted to resolve the situation, and has suggested possible errors in the work of Metlay and Kimball, and of Schüler and Bingel. However, in my opinion, the electron impact situation has still remained unclarified.

At Liverpool, measurements of the electron affinity of oxygen have been carried out in carbon monoxide, carbon dioxide and oxygen, and have yielded values of 1·75 ± 0·1, 2·05 ± 0·2 and 2·0 ± 0·1 eV., respectively. The only apparent differences between the conditions of measurement lies in the initial kinetic energy of the ions at the electron energy at which they are first formed. These energies are, respectively, 0, 2·7, 1·6 eV. These measurements, and almost all earlier measurements, have been carried out using an electron beam which is not entirely monoenergetic, and calculations have shown that, due to the technique employed in obtaining the appearance potential of ions of a given kinetic energy, the spread in the energy of the electrons becomes of considerable importance where the initial kinetic energy of the ions is appreciable. Correcting for this error, the values for the electron affinity of oxygen obtained in carbon monoxide, carbon dioxide and oxygen become respectively 1·6 ± 0·2, 1·65 ± 0·3 and 1·5 ± 0·2 eV., all of which are compatible with the photo-detachment values. This error would be expected to occur in all electron impact experiments which do not employ an effective electron energy filter, and some supporting evidence has apparently recently accrued from the work of Randolph and Geballe[10], in which great care is taken to eliminate any error due to electron energy spread, and in which a value of 1·52 ± 0·1 eV. has been obtained. However, the appearance potential for O^- ions reported by these workers seems to be remarkably low. It would then appear that values of E (O) obtained by the electron impact method are subject to a subtle experimental error which makes most values obtained in this way incorrect unless the kinetic energy of the ions involved can be measured and allowance made. There no longer seems any reason to doubt the value of 1·465 eV., obtained by the photo-detachment method.

I wish to thank Prof. J. D. Craggs for his help and guidance, and Dr. R. Thorburn for many helpful discussions. I also wish to acknowledge receipt of a maintenance grant from the Department of Scientific and Industrial Research.

A Spectrophotometric Method for the Determination of Chlorine

Rapid determination of low concentrations of chlorine is very important in analysis. The estimation of this element in the air (in industrial towns and factories) as well as its quantitative estimation in the laboratory work require rapid and precise methods.

In this communication a spectrophotometric method for the estimation of low concentrations of free chlorine is described. The chlorine was dissolved in an organic liquid and the absorption spectrum of the solution was examined in the ultra-violet region. This spectrum is most probably due to the formation of some complex compounds of chlorine. The absorption maximum of chlorine dissolved in carbon tetrachloride has a wave-length of about 335 mμ (Fig. 1) and its height is proportional to the concentration of chlorine. A standard curve (Fig. 2) was established with a Zeiss universal spectrophotometer. The concentration of the chlorine in the standard solution of the carbon tetrachloride was determined by potentiometric titration, and by dilution of this standard solution other samples were prepared. The sensitivity of the spectrophotometric method is about 2×10^{-5} M, that is, about 1 μgm. chlorine/ml. The other methods for the determination of chlorine (estimation as chloride ion or colorimetric analysis) are too slow and rather unreliable[1,2].

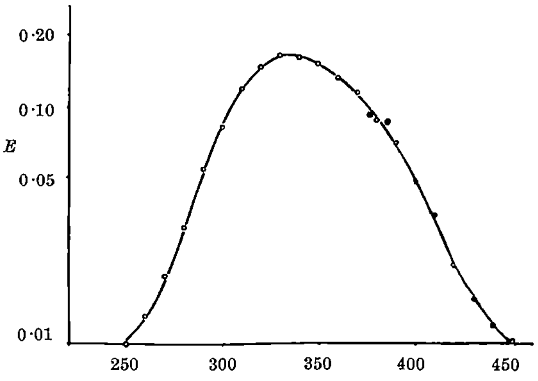

Fig. 1

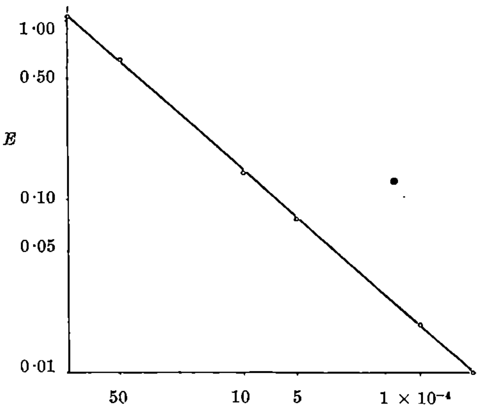

Fig. 2

In the same way, chlorine dissolved in other organic liquids such as chloroform, trichlorethylene, tetrachlorethylene, acetone, etc., can be determined. However, these analyses are less sensitive than those with carbon tetrachloride.

The method was used for the direct measurement of the chlorine content of carbon tetrachloride and chloroform irradiated with X-rays. It is also useful for the estimation of low concentrations of chlorine in the air and other gases, and for the chemical analysis of free chlorine.

I wish to thank Dr. M. Horák, of the Chemical Institute of the Czechoslovak Academy of Sciences, for the measurement of the ultra-violet spectrum, and Mrs. Šulcová and Mr. Hruška, of the Institute of Nuclear Research, for their help in the experimental work.

Polymorphic Transitions in Anhydrous Sodium Sulphate

The heat capacity of anhydrous sodium sulphate has been measured recently in a water calorimeter by Kreidl and Simon[1], who observed only one high-temperature transition, at about 238° C. However, there are two known polymorphic transitions between room temperature and 300° C.: (1) the transformation of the stable low-temperature form V to the intermediate form III and (2) transformation of III to the stable high-temperature form I. The heat of transition observed by Kreidl and Simon was nearly equal to the sum of the heats of the two known transitions. They concluded that in the presence of water, the transition V ⟶ I occurs directly and reversibly, and supported this conclusion with X-ray diffraction data. More recently, Bird[2] has reported an irreversible transformation, V ⟶ I, upon heating sodium sulphate in the absence of water. This occurred at a considerably lower temperature of about 176° C., and is based on comparison of high-temperature X-ray diffraction patterns.

We have now subjected anhydrous sodium sulphate (reagent grade) to differential thermal analysis in the absence of water, using a high-sensitivity apparatus[3]. The rate of heating was maintained constant at 12 deg. $min.^{-1}$ over the entire range 25–350° C.; however, it was not possible to control the rate of cooling so closely. The curves are shown in Fig. 1. It should be noted that the reaction peak temperatures are by no means absolute, but are constant only for a given set of experimental conditions.

Only one transition peak was observed in the differential thermal analysis curves, beginning around 235° C. on heating. The transition is completely reversible, even though the sample was free of water. The areas under the peaks, which are proportional to the heats of the reaction involved, are of the same order of magnitude for both the endothermic (heating) and exothermic (cooling) peaks.

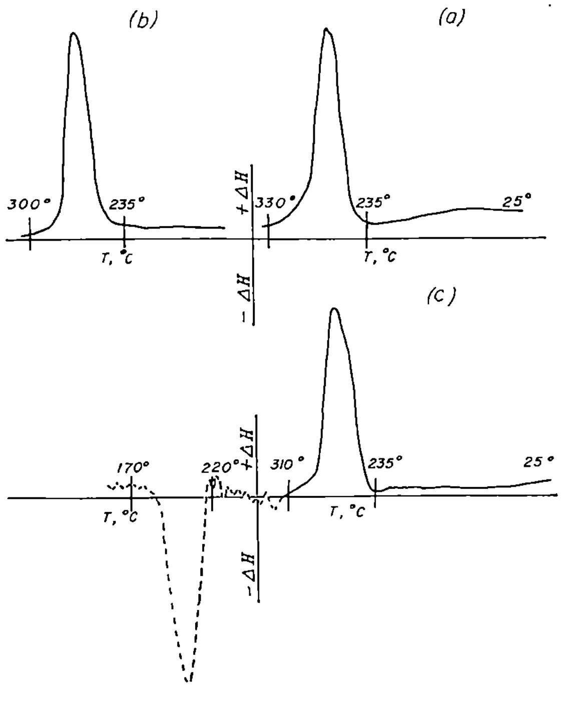

Fig. 1. Differential thermal analysis curves of anhydrous sodium sulphate between 25° and 350° C. (*a*) Heating curve, (*b*) heating curve obtained after cooling the sample (*a*) to 25° C.; (*c*) heating (solid line) and cooling (dotted line) curves

We thank Mrs. M. P. Lewis for her kind assistance in operating the differential thermal analysis apparatus.

BIOCHEMISTRY and PHYSIOLOGY

Proton Transfer and Supercontraction in Actomyosin

It has been previously reported that the synaeresis of actomyosin gels with adenosine triphosphate is accompanied by changes in the X-ray diffraction pattern indicating that some part of the actin–myosin complex undergoes supercontraction[1]. The recent observation by Goodall[2] that one or more protons at each active site are involved in the production of tension in the myofibril is in line with my experiments, which suggest that the supercontraction of myosin (or actomyosin), long postulated as the fundamental basis of muscle contraction[3], might also be due primarily to some specific transfer of protons.

Earlier investigation showed that actomyosin apparently supercontracted on acidification, but the drastic nature of the treatment (2 per cent acetic acid) did not preclude the possibility of artefacts from partial hydrolysis. More recently, however, I have succeeded in preparing films of actomyosin from very weakly acid dispersions of the gel, and from neutral films weakly acidified and washed at neutrality, that show the characteristic reflexion at 4·65 A. on the meridian of the X-ray diffraction diagram. In every case, the hydrogen ion, rather than any anion combination of chloride, phosphate and acetate, appears to be responsible for the change.

The transformation into the supercontracted state, as judged by this test, becomes detectable below *p*H 6·0. Thixotropic gels of actomyosin allowed to stand for 48 hr. at *p*H 5·0, for example, form insoluble precipitates indistinguishable from those formed on addition of adenosine triphosphate at neutrality. When actomyosin from fish dorsal muscle is dried from a slightly acidified dispersion of the gel, the X-ray diffraction diagram is always characterized by a marked cross-β pattern, and at *p*H values in the region of 5·0 the meridional reflexion at 4·65 A. predominates over the 5·1 A. α-reflexion. Again, the X-ray diffraction diagrams of similarly prepared actomyosin gels dried at neutrality show a progressive increase in the cross-β pattern with increasing acidification and time of treatment. Immersion of the films at *p*H 5·0 for 48 hr., for example, followed by washing at neutrality, drying and mounting, results in the appearance of a clear supercontracted component after orientation by stretching (Fig. 1).

The ease with which these small changes of *p*H bring about the X-ray signs of supercontraction in actomyosin suggests that the system is extremely sensitive to protons. It might be argued that although adenosine triphosphate induces supercontraction at

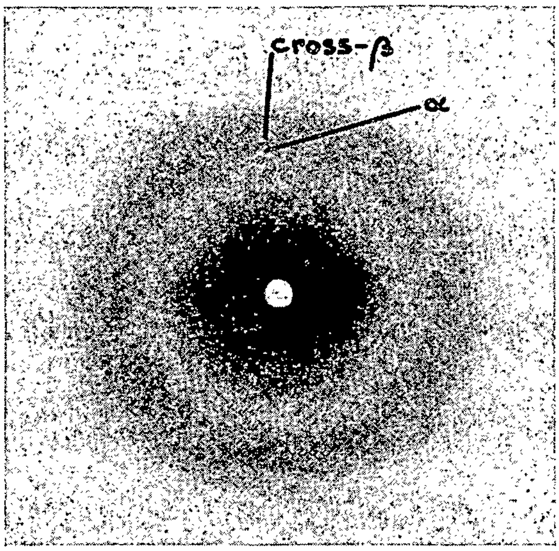

Fig. 1. X-ray diagram of a film of actomyosin dried at neutrality, treated for 48 hr. at pH 5, washed to neutrality, re-dried and oriented by stretching

neutrality, the attendant drop in pH during splitting[4] is in fact the cause of an artefact. It seems more likely, however, that the transference of protons during the splitting of adenosine triphosphate is the fundamental event itself, and that experiments involving protons alone are simply another expression of the fact that local migration of protons to some part of the actin–myosin complex causes collapse of specific polypeptide chains. Overall shortening of the complex will then take place according to the arrangement of the sites where the adenosine triphosphate is split.

I thank Prof. W. T. Astbury for his encouragement of this work, Dr. G. N. Graham for assistance in the preparation of actomyosin, and Mr. A. Millard for the photographic reproduction of Fig. 1. The work, which is aided by a grant from the Muscular Dystrophy Associations of America, Inc., will be described in detail in due course.

Effect of Fatty Acid Mixtures on the Rice Stylet Nematode (*Tylenchorhynchus martini* Fielding, 1956)

In the course of other experiments, the metabolic fatty acids produced by *Clostridium butyricum* Prazmowski were shown to be active against *Tylenchorhynchus martini* Fielding, 1956. Fatty acids in aqueous solutions at those concentrations extracted from artificial culture filtrates proved highly effective in inactivating *T. martini*[1].

In the present work all possible combinations of the extracted acids—butyric, propionic, acetic and formic—were prepared at concentrations of 10^{-2}, 10^{-3} and 10^{-4} M in distilled water. Equal quantities of each acid in each combination were prepared at the various concentrations. Twenty active nematodes were submerged in each acid solution at each concentration until all the nematodes were quiescent. If the nematodes remained quiescent for 15 min. after they had been removed from the acid solutions into water they were considered to be inactivated. The pH of the acid solutions was determined.

Although nematode response was variable, it is evident from the results presented in Fig. 1 that the combination of butyric and propionic acids was more effective at 10^{-3} and 10^{-4} M than either butyric or propionic acid alone. Other results (not presented in Fig. 1) show that any combination containing 2, 3 or 4 of the above-mentioned acids was more effective than any one acid alone at the same molar concentration. Effectiveness of the acid mixtures was related to combined molecular weights. Thus, butyric and propionic acid mixtures were more effective than propionic and acetic acid mixtures. Relative effectiveness of the individual acids was dependent on their molecular weights and decreased in the order of butyric, propionic, acetic and formic. The pH-range of all solutions was between 3·3 and 4·4.

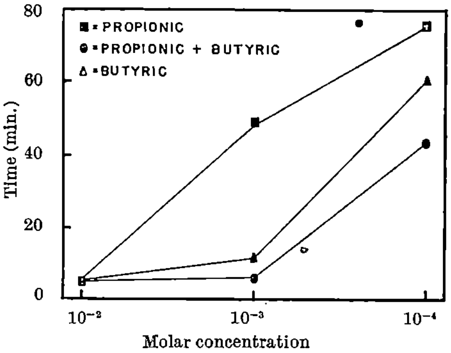

Fig. 1. Time in minutes required for inactivation of *T. martini* in water solutions of butyric and propionic acids and a mixture of the two acids at three different molar concentrations

Other experimental procedures thus far have failed to elucidate the mechanism of the effects of mixtures and single acids on this nematode.

Thanks are due to Dr. John P. Hollis at Louisiana State University for his constructive advice during this study.

Free Radicals from Chlorpromazine

The report has been made recently of the isolation in urine of a metabolite of chlorpromazine which was designated as a free radical from its electron spin resonance[1]. Absorption data revealed no distinct characteristics in the ultra-violet and visible ranges. The same compound was formed also by photo-oxidation with ultra-violet light. The oxidation-level of the free radical was thought to be intermediate between chlorpromazine and its sulphoxide, and, as a result, a provisional formula was suggested involving the heterocyclic sulphur.

As a result of oxidation of chlorpromazine with hydrogen peroxide and peroxidase, Cavanaugh[2] obtained a red reaction product which had an absorption maximum at 527 mμ as well as an identical absorption in the ultra-violet as the sulphoxide. It was concluded from kinetic data that this substance was a precursor of the sulphoxide.

Finally, Dushinsky and Lishkova[3] obtained a red reaction product from the oxidation of chlorpromazine and ceric sulphate, which was considered to be a free radical from titrimetric evidence.

We have found chlorpromazine easily oxidized by ferric salts[4] in dilute acidic media, resulting in a red reaction product. The reaction appears to be specific for it does not occur with cupric, mercuric, zinc, molybdate, cobaltic, manganic or chromic ions. Nor does it occur when the iron is complexed as in ferricyanide. There is also some specificity on the part of chlorpromazine, for the sulphoxide does not give the reaction. However, if concentrated sulphuric acid is added, the sulphoxide does react, as, of course, does chlorpromazine[5]. This may be useful in differentiating the two compounds.

The red reaction product formed has absorption maxima at 530 and 255 mμ and a broad band in the range 270–275 mμ. This differentiates it from the substance investigated by Forrest *et al.*[1]. The absorption in the 270 mμ range is characteristic of the sulphoxide[6], and one would be led to agree with the proposal that the red-coloured reaction product is a precursor of the sulphoxide. However, this cannot account for the fact that the sulphoxide itself forms a red reaction product with concentrated sulphuric acid which has an absorption maximum at 530 mμ.

The stoichiometry of the reaction may be determined by assuming that better than 90 per cent of coloured reaction product is formed in concentrated sulphuric acid. This has been found true for other phenothiazine derivatives[7], and it can be used as a standard to determine the amount of coloured reaction product formed in the reaction with ferric ion. This, together with the determination of ferrous ion formed using different concentrations of reactants (Table 1), indicates that two molecules of ferric ion are necessary to oxidize chlorpromazine. This stoichiometry would favour a quinoid formulation rather than a free radical for the coloured reaction product. The ease with which chlorpromazine reacts with ferric ion suggests that the pharmacological activity of chlorpromazine might involve the cytochrome system. Evidence in this direction has been recorded in the literature[8].

Isolation of an Activator for Phospholipase *D*

WHILE working on the purification of phospholipase *D* for use in connexion with other studies on phospholipids[1] we observed that incubation with the enzyme released choline from commercial soy bean lecithin, but not from synthetic L-α-dipalmitoyl lecithin or carefully purified lecithins from egg, yeast and soy beans. The apparent discrepancy has been resolved by isolation of an activating phospholipid from commercial soy bean lecithin preparations.

The incubations were conducted in 2 ml. of acetate buffer, *p*H 5·8, containing 0·05 molar calcium. The requirement for the latter ion as reported by Davidson *et al.*[2] was not affected by the presence of the activator. Enzymatic activity was determined by assaying the amount of choline liberated[3].

The enzyme was purified by centrifugation at 20,000*g* of an aqueous extract of cabbage acetone powder. The supernatant solution was lyophilized, redissolved in one-tenth the original volume of water and precipitated between 40 and 66 per cent of saturation with ammonium sulphate.

This procedure increased the specific activity eighty-fold. The total enzymatic activity recovered from the precipitation was approximately twice that of the original extract, apparently because of the loss of an inhibitor which has been previously reported[4,5]. Cabbage acetone powder provides an exceptionally stable source of the enzyme; a preparation stored at −10° C. has yielded active extracts for more than two years.

The activator was first separated from substrate by chromatography on a silicic acid column. However, this separation could be more rapidly effected by a precipitation procedure in which 100 ml. of ethanol was added to a solution of 5 gm. of commercial lecithin in 25 ml. of ether. The residue from evaporation of the mother liquor was reprecipitated from 10 ml. of ether.

Chromatography of 200 μgm. aliquots on silicic acid impregnated paper in system *A* of Marinetti and Stotz[6] showed that lecithin was absent from the combined precipitates but that a slightly more polar spot, similar in R_F to phosphatidyl inositol, was present

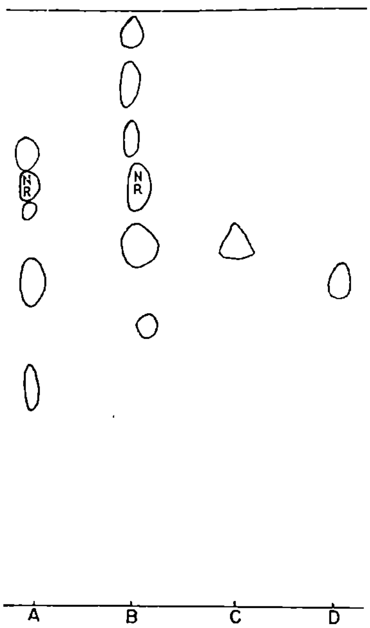

Fig. 1. Chromatograms of soy bean phospholipids on paper impregnated with silicic acid. Ascending solvent was di-*iso*butyl ketone/acetic acid/water, 40 : 30 : 7. *A*, ethanol-insoluble precipitate containing activator; *B*, ethanol-soluble fraction; *C*, lecithin substrate; *D*, activator after purification by column chromatography. All spots were visualized by immersion in dilute rhodamine *G*. Spots labelled *NR* also reacted with ninhydrin

as a major component. Almost none of this latter substance was present in the mother liquor (Fig. 1).

Separate incubations of precipitate, mother liquor residue and a reconstituted mixture of the two components in amounts equivalent to a total of 20 mgm. of starting material released 0·02, 0·17 and 0·52 μmole of choline respectively. The latter figure was in good agreement with the 0·59 μmole released from 20 mgm. of starting material.

Purified lecithin for use as a substrate in further experiments was obtained by chromatography of the residue from evaporation of the mother liquor on alumina and silicic acid according to the procedures of Hanahan and Jayko[7] and Lea, Rhodes and Stoll[8].

The activating factor was purified from the crude alcohol precipitates by chromatography on silicic acid. Fractions of the eluates from these columns were examined by paper chromatography and by incubation with 10 mgm. amounts of pure lecithin and phospholipase *D*. The results indicated that the enhancement of the hydrolysis of lecithin was associated with the component that was slightly less mobile than lecithin on the impregnated papers of Marinetti and Stotz. The chromatographic properties of this substance were indistinguishable from those of a phosphatidyl inositol prepared from peas[9] which was also found to activate the hydrolysis of lecithin by phospholipase *D*.

In the final isolation procedure columns of Mallinckrodt silicic acid containing 30 gm. adsorbent/gm. of lipid were eluted with chloroform–methanol 9 : 1 v/v until the yellow colour moving down the semi-translucent column was well separated from an opaque band which remained at the top. The latter was isolated by extrusion of the column, and a slurry of the extruded silicic acid in chloroform–methanol was poured into a smaller column. This material was eluted with chloroform–methanol 9 : 2 v/v until no weighable residue remained from the evaporation of 2 ml. of eluate. Chromatographically pure material could then be recovered by elution of the column with chloroform–methanol 7 : 3.

Inositol, but no choline or amines reacting with ninhydrin, could be identified chromatographically[10] in the water-soluble products from hydrolysis of this fraction for 48 hr. in 6 *N* hydrochloric acid. This, together with the chromatographic properties, indicates that the activator is the phosphatidyl inositol characterized by Okuhara and Nakayama[11] and by Hanahan and Olley[12].

The effects of the purified activator on the hydrolysis of lecithin are summarized in Table 1.

Table 1. Effect of Increasing Amounts of Activator on Total Choline released in 15 min. from an Incubation Mixture containing 5 mgm. Lecithin and 0·12 mgm. Enzyme/ml.

Mgm. activator/ml. of incubation mixture	Choline released (μmoles)
0·0	0·12
0·07	0·38
0·25	0·82
0·50	1·77
1·0	2·05
2·5	2·09

Another enzyme, phospholipase *B* of *Penicillium notatum*, has been shown by Dawson[13] to hydrolyse the ester bonds of lecithin only if phosphatidyl inositol or certain other lipid activators are present. It is possible that similar mechanisms are involved in the activation of the two enzymes, although the role of the inositide is still obscure. The two systems appear to differ markedly in their response to calcium ion, which is obligatory for phospholipase *D* activity, but which has been reported[13] to inhibit the activation of phospholipase *B*, perhaps by interfering with the formation of a complex between lecithin and phosphatidyl inositol.

Prevention of Freezing Damage to Living Cells by Dimethyl Sulphoxide

Polge, Smith and Parkes[1] first reported the protective action of glycerol against the adverse effects on spermatozoa of freezing and thawing. Lovelock[2] found that the protective action of glycerol was shared with a number of other neutral solutes of low molecular weight, including methanol, acetamide and glyceryl monoacetate. Using the extent of hæmolysis of red blood-cells as a measure of damage

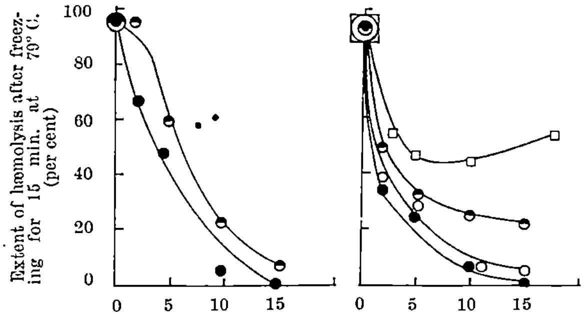

Fig. 1. The protective action of glycerol and of dimethyl sulphoxide against the hæmolysis of human (left) and bovine (right) red blood-cells by freezing and thawing. (◓, After prior exposure to glycerol for 30 sec.; ●, after prior exposure to dimethyl sulphoxide for 30 sec.; □, after prior exposure to glycerol for 2 hr.; ○, after prior exposure to dimethyl sulphoxide for 2 hr.)

by freezing, it was concluded that the principal protective action of the neutral solutes was a simple consequence of their ability to prevent the excessive concentration of electrolytes and other substances that otherwise occurs on freezing. The protective property is limited to substances that are in themselves not toxic, have a low molecular weight, a high solubility in aqueous electrolyte solutions and an ability to permeate living cells. The number of solutes capable of fulfilling these conditions is small, and so far glycerol most closely approaches the ideal protective agent. Some cells, however, are impermeable to glycerol, for example, bovine red blood cells, and with these glycerol is of little use in their preservation by cold storage. An alternative solute with a greater permeability to living cells is dimethyl sulphoxide. This communication reports the protective action of dimethyl sulphoxide against freezing damage to human and bovine red blood cells and to bull spermatozoa.

Freshly drawn human or bovine red blood cells were suspended in 0·16 *M* sodium chloride solution containing 0·1 per cent glucose. The cell suspensions were cooled to 0° C. and to them was added either glycerol or dimethyl sulphoxide to provide final concentrations of 2, 5, 10 and 15 per cent by weight. After allowing intervals of between 10 sec. and 2 hr. for the solute to penetrate the cells, they were frozen to −79° C. by immersing the test-tubes containing the suspensions in a bath of ethanol and solid carbon dioxide. After freezing for 15 min., the cell suspensions were thawed by immersion in warm water (35° C.). The extent of hæmolysis was observed after sedimenting the undamaged cells in a centrifuge. The results of this experiment are shown in Fig. 1.

Bull semen was mixed with an equal volume of egg-yolk – citrate diluent[3] and cooled slowly during 1 hr. to + 4° C. Solutions of either dimethyl sulphoxide or glycerol in 0·16 *M* sodium chloride containing 0·1 per cent glucose, also at + 4° C., were then mixed with the suspensions of spermatozoa in the proportion 9 to 1. After 30 min. at + 4° C., to allow the permeation of the cells by the solutes, the suspensions contained in small test-tubes were frozen to − 30° C. and left at this temperature for 5 min. Part of the frozen suspension at − 30° C. was thawed and examined for motility and part was frozen further to − 79° C. After 15 min. at the lower temperature, the suspensions were thawed in warm water at + 35° C. and examined for motility. The results showed that dimethyl sulphoxide provided some protection against the damaging effects of freezing, but that, under the experimental conditions used, this was less than the protection afforded by glycerol. Motility persisted for several hours in 15 per cent dimethyl sulphoxide at room temperature, thereby suggesting that the toxicity of this solute, at least to spermatozoa, is low.

With both bovine and human red blood-cells, dimethyl sulphoxide penetrates the cells more rapidly than does glycerol and less of the solute is required for complete protection against damage by freezing. With bovine red blood-cells, the difference in rate of penetration was outstanding: 2 hr. equilibration with glycerol before freezing gave only poor protection whereas 30 sec. with dimethyl sulphoxide was sufficient for complete protection. Dimethyl sulphoxide does not, under the conditions used, appear to be as effective as glycerol in the protection of bull spermatozoa, but (in view of the sensitivity of this cell to freezing damage) the partial protection observed is of some interest and is shared by few other solutes[4].

A wide variety of living tissues can now be preserved in the frozen state through the protective action of glycerol; some, however, because of their large size or the impermeability of their membranes to glycerol are permeated by this substance so slowly that protection is slight. With this type of tissue, dimethyl sulphoxide, provided it proves to be otherwise harmless, may serve as an alternative protective agent.

Ethylenediamine Tetraacetate and the Intestinal Absorption of Vitamin B_{12}

For the laboratory, as opposed to the clinical, analysis of the defective absorption of vitamin B_{12} in pernicious anæmia caused by the lack of Castle's intrinsic factor, several methods have been developed since radioactive preparations of the vitamin became available. In the first the absorption is studied by measuring the radioactivity of the fæces produced by gastrectomized rats given a test dose of labelled vitamin B_{12}, with or without an intrinsic preparation[1-3]. The defect of absorption in these animals closely resembles that found in pernicious anæmia in humans[4]. In a second method slices or homogenates of rat liver or strips of rat intestine are exposed to a preparation of hog intrinsic factor and simultaneously or afterwards to labelled vitamin B_{12}[5-7]. With this technically simpler *in vitro* method hog intrinsic factor was found to increase the uptake of vitamin B_{12} by the tissue preparation. This effect is dependent on the presence of calcium in the incubation fluid and can be abolished by the addition of ethylenediamine tetraacetate (as the disodium salt dehydrate) to the medium[8,9].

In this communication results on the effect of ethylenediamine tetraacetate on the intestinal absorption of radioactive vitamin B_{12} by gastrectomized rats are presented. We preferred the use of animals in which the entire stomach had been resected because in this way a possible influence of endogenous

intrinsic factor is excluded. The rats were given 0·005 µgm. vitamin B_{12}–^{58}Co and 0·5 ml. rat gastric juice with 1 ml. tap-water or 1 ml. 5 per cent or 1 ml. 10 per cent ethylenediamine tetraacetate solution by a thin rubber catheter introduced into the œsophagus.

The radioactivity of the fæces collected over the following four days was determined. The results summarized in Table 1 indicate that the large amounts of ethylenediamine tetraacetate, which were sufficient to cause diarrhœa in a number of animals, did not impair the intestinal absorption of vitamin B_{12}.

Apart from this lack of effect there are other points of disagreement between the results obtained with the *in vitro* method and the observations using gastrectomized rats. In the operated animal, rat gastric juice or rat stomach preparations are the only effective sources of intrinsic factor, while different hog intrinsic factor preparations are inactive[4]. The effect of hog intrinsic factor concentrates promoting the uptake of radioactive vitamin B_{12} by tissue preparations *in vitro* is not shared by rat gastric juice[10]. In the *in vitro* test, rat liver slices, which are exposed to a hog intrinsic factor concentrate and then washed prior to incubation with vitamin B_{12}, show an increased uptake, while in the gastrectomized rat intrinsic factor is active only when given simultaneously with labelled vitamin B_{12}[4]. The results of the *in vitro* experiments with rat liver slices are therefore difficult to evaluate when one attempts an analysis of the physiologically characteristic activity of the intrinsic factor which promotes the intestinal absorption of vitamin B_{12}.

Role of Liver in Metabolism of Chlorpromazine

In previous studies[1] we demonstrated that the intact rat was capable of demethylating chlorpromazine-(N-methyl)-^{14}C when production of carbon dioxide was used as an index of demethylation. The liver seemed to be the likely tissue responsible for these findings, since Mueller and Miller[2] had found that homogenates of rat liver were capable of demethylation. La Du *et al.*[3] later developed a simpler system for demethylation using homogenates of rabbit, rat and guinea pig livers. However, using the system of La Du *et al.*, Salzman and Brodie[4] reported that no demethylation of chlorpromazine occurred with rabbit liver. Since we had observed the *in vivo* demethylation of chlorpromazine, we decided to study its *in vitro* demethylation by fortified homogenates of rabbit and rat liver prepared according to these procedures[2,3].

Non-fasted adult male rabbits (3·0–4·0 kgm.) and adult male Long Evans rats (225–250 gm.) were killed by a blow on the head, exsanguinated, and the livers were quickly removed. Homogenates of rat liver initially were made according to the procedure of Mueller and Miller, and fortified with their medium consisting of nicotinamide, adenosine triphosphate, di- and tri-phosphopyridine nuleotides, magnesium chloride, potassium chloride and phosphate buffer, *p*H 7·4, except that 0·12 µmole of glucose-6-phosphate was substituted for glucose-1,6-diphosphate. Rat livers were also homogenized according to the procedure of La Du *et al.*, and fortified with their medium consisting of nicotinamide, triphosphopyridine nucleotide, magnesium chloride and phosphate buffer, *p*H 7·4. The latter homogenates of rat liver were also fortified with the medium of Mueller and Miller. Homogenates of rabbit liver were prepared according to the procedure of La Du *et al.*, and fortified with their medium.

Incubations of labelled chlorpromazine with 33 per cent homogenates prepared according to the procedure of La Du *et al.*, and 10 per cent homogenates prepared according to the method of Mueller and Miller were conducted aerobically in closed vessels for 1 hr. at 37° C. in a Warburg apparatus. The supporting media contained 110–115 µgm. chlorpromazine and approximately 2·7 × 10^5 c.p.m. Liberated carbon dioxide was trapped as carbonate in 10 per cent sodium hydroxide solution in a centre well. At the end of incubation trichloracetic acid was added to the contents of the main chamber in order to liberate bound carbon dioxide. After another hour of incubation the carbonate in the centre well was precipitated as barium carbonate, and radioactivity was determined[1]. The influence of reagents or homogenates inactivated by heat on the liberation of the carbon-14 label was followed by incubating the complete medium with the solution used for homogenization or with homogenates heated at 100° C. for 5 min.

The results are reported in Table 1. Under the conditions of these experiments, it is evident that chlorpromazine-(N-methyl)-^{14}C was demethylated by homogenates of rabbit liver when adequately fortified. On the other hand, the labelled compound is demethylated by homogenates of rat liver prepared by either procedures for homogenization only when the medium of Mueller and Miller was used.

The ability of the liver to diminish the pharmacological activity of chlorpromazine by oxidation of the

Table 1. PRODUCTION OF CARBONATE-^{14}C FROM CHLORPROMAZINE-(N-METHYL)-^{14}C BY HOMOGENATES OF RABBIT AND RAT LIVER

sulphur atom of the phenothiazine nucleus was suggested by earlier observations. Salzman and Brodie[4] found that homogenates of rabbit liver yielded chlorpromazine sulphoxide, which is pharmacologically less active than the parent compound. More recently, Kamm *et al.*[5] observed that homogenates of the livers of guinea pigs, rabbits, dogs, mice and monkeys also produced chlorpromazine sulphoxide. The present findings re-emphasize the capacity of the liver to diminish the pharmacological activity of chlorpromazine since pharmacological testing in these laboratories showed that 2-chloro-[10-(methylaminopropyl)]-phenothiazine hydrochloride and 2-chloro-[10-(aminopropyl)]-phenothiazine hydrochloride were less active than chlorpromazine[6].

We wish to thank Dr. W. Holmes for his advice during the initial phases of these studies.

Selective Permeability of Living Tissues to Carbonic Acid

RECENT investigations of the influence of carbon dioxide on the action of certain drugs[1] and on antibody fixation[2] have suggested that this substance may be able to diffuse freely through the cell membrane and thereafter modify from inside the reactivity of some specific receptors. It has been demonstrated by Arvanitaki[3] and more recently by Caldwell[4] that carbon dioxide can alter the intracellular *p*H of certain nerve and muscle fibres.

The following investigations provide evidence that carbonic acid diffuses rapidly through living tissues and membranes.

Experiments were carried out with carp (*Cyprinus carpio*) swim-bladder, rabbit bladder and guinea pig colon. The experimental apparatus is shown in Fig. 1. The inside of the organ was filled with Tyrode solution buffered with 1·2 m*M* $NaHCO_3$ and adjusted to *p*H about 7·2. The liquid outside the membrane was a Tyrode solution buffered either with $NaHCO_3$ (1·2 m*M*) or with sodium maleate (12 m*M*). In the first case, the *p*H was adjusted to 4·8 by saturation with carbon dioxide, while in the second case the *p*H was lowered to the same value by addition of the proper quantity of maleic acid. The *p*H of the internal solution was measured potentiometrically at different times. Experiments with the fish swim-bladder were performed at room temperature (18 ± 2° C.) while those with mammalian tissues were carried out at 37° C.

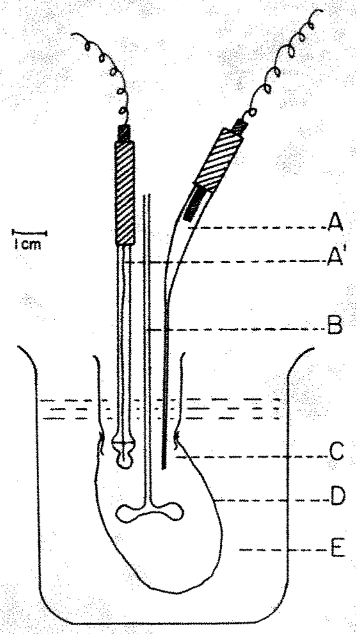

Fig. 1. Experimental apparatus. *A* and *A'*, electrodes; *B*, mixer; *C*, internal solution; *D*, membrane; *E*, external solution

When the *p*H of the external solution was lowered by saturation with carbon dioxide, a gradual decrease of the *p*H of the internal solution was regularly observed. On the contrary, when the external solution was acidified with maleic acid, no significant changes of the *p*H of the internal solution were observed. A typical experiment is represented in Fig. 2. Similar negative results were obtained by acidification of the external solution with acetic, benzoic, succinic or hydrochloric acids: none of these acids was able to acidify the solution on the other side of the membrane.

In certain experimental conditions the *p*H of the internal solution can be brought down to a level which is lower than that of the external one. That happens when the external Tyrode solution is buffered with 60 m*M* $NaHCO_3$ and saturated with carbon dioxide. The result of such an experiment is presented in Fig. 3.

Experiments performed by acidifying the internal fluid have proved that the behaviour of the tissue

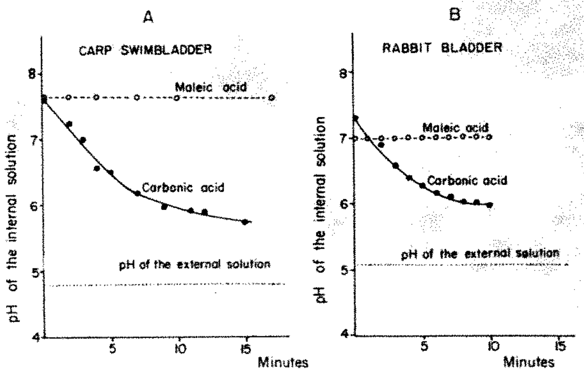

Fig. 2. Modifications of the *p*H of the internal solution after acidification of the external solution with carbonic acid or with maleic acid

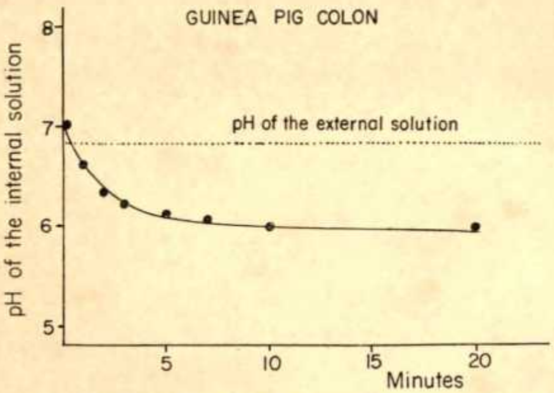

Fig. 3. Modification of the pH of the internal solution after saturation with carbon dioxide of the external solution, buffered with 60 μmol./l. of $NaHCO_3$

is very similar: acidification of the external solution was observed with carbonic acid but not with maleic acid.

These results suggest that carbonic acid can pass through the living membrane and cause the acidification of the internal medium. It can be postulated that what occurs with such complex tissues as the bladder or colon may also occur with single cells. But this remains to be proved. The selective permeability of carbonic acid has not been observed with artificial membranes such as 'Cellophane' tubing, and in this case the movements of the acids obey the general laws of simple diffusion.

Distribution of 5-Hydroxytryptamine in Scorpion Venoms

IN previous communications[1,2] the occurrence of high concentrations of 5-hydroxytryptamine in the venom of *Leiurus quinquestriatus* was reported. Since then, the venom of *Buthotus minax* L. Koch (another common local species) has been found to contain much smaller amounts of 5-hydroxytryptamine, and this observation has been correlated with the histological appearance and histochemical reactions of the venom glands.

The method of obtaining venom and its subsequent treatment has been described previously, as have the histological methods used[1,2]. The venoms of both *B. minax* and *L. quinquestriatus* were obtained over the same period of the year, and estimations of the 5-hydroxytryptamine content were made on the pooled venom of each. Sections of venom glands were prepared at the same time, and treated simultaneously. The assay of 5-hydroxytryptamine was carried out on the fundus of the rat's stomach by Vane's method[3]. This preparation is particularly sensitive to 5-hydroxytryptamine and is also relatively specific for this substance in the presence of hyoscine (10^{-7} gm./ml.). Specificity was also tested by antagonizing venom-induced contractions with 2-bromo-lysergic acid diethylamide (5×10^{-6} gm./ml.) (we are indebted to Sandoz, Ltd., Basle, for a gift of 2-bromo-lysergic acid diethylamide).

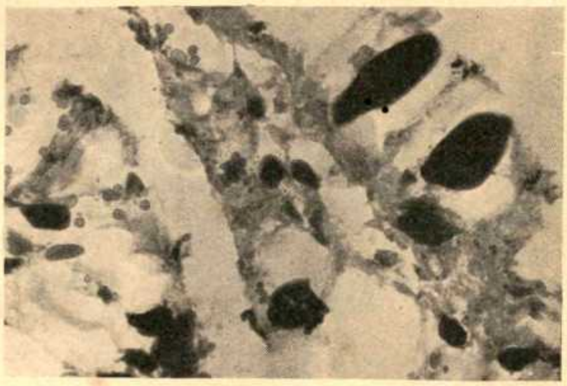

Fig. 1. *L. quinquestriatus* venom gland, 10μ, argentaffin reaction with Fontana's ammoniacal silver method. (× 400)

Assays of the venom of *B. minax* on the fundus of rat's stomach indicated a concentration of 0·03–0·04 μgm. 5-hydroxytryptamine/mgm. dry weight of venom. Paper electrophoretic separations when treated with acid ninhydrin[4] showed no fluorescence in ultra-violet light. Estimates of 5-hydroxytryptamine in the venom of *L. quinquestriatus* on the rat fundus preparation confirmed the previously reported concentration of 2–4 μgm. 5-hydroxytryptamine/mgm. of dry venom.

The general organization of the venom gland of *B. minax* is similar to that of *L. quinquestriatus*; but the rather prominent coarse granules that appear in the latter gland after formalin fixation are much less abundant in the case of *B. minax*. A high proportion of these coarse granules in the glands of *L. quinquestriatus* are argentaffin (Fig. 1), whereas no argentaffin structures were seen in the case of *B. minax* (Fig. 2). Similarly, in sections of *L. quinquestriatus* granules which give a positive diazo reaction with fast red salt *B* are seen, but in sections of *B. minax* the diazo reaction is negative. Distinct yellow-green fluorescence in ultra-violet light was observed in a proportion of the coarse granules and some fine-granular cells in *L. quinquestriatus*. No fluorescence was seen in sections of the glands of

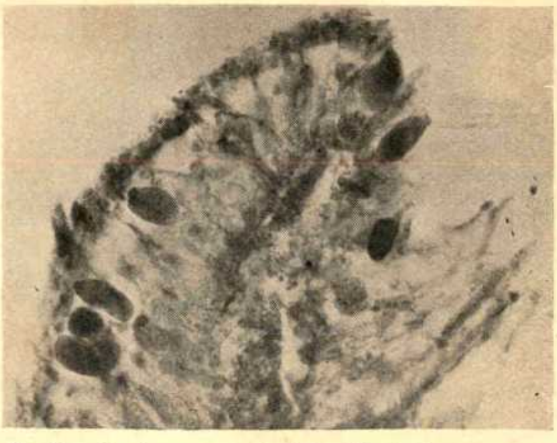

Fig. 2. *B. minax* venom gland, 10μ, Fontana's ammoniacal silver method. (× 450)

B. minax. The indole reaction was marked in many cells in sections from *L. quinquestriatus* glands ; but sections from *minax* glands showed only a few faintly positive structures. This reaction does not appear to be so specifically connected with the coarse granules as are the other histochemical methods used, but seems to spread throughout whole cells, which exhibit a very fine granular structure. These same cells give a positive Sakaguchi reaction for arginine.

Sections of venom glands of *Parabuthus hunteri* (a less common species here) have also been examined and found to show the same structure and histochemical reactions as do sections from glands of *L. quinquestriatus* but in much less-marked fashion. 5-Hydroxytryptamine is present in this venom in sufficient quantity to produce fluorescence after treatment with acid ninhydrin ; but insufficient venom has been available so far to give a reliable estimate of the content of 5-hydroxytryptamine.

It seems remarkable that species of the same family (Buthidae) should show such a marked difference in the 5-hydroxytryptamine content of their respective venoms, that of *B. minax* being about one hundredth of that found in *L. quinquestriatus*. So far as can be observed, *minax* venom is as effective in its normal function of paralysing active prey as is the venom of *L. quinquestriatus*, and this leads to speculation as to whether the 5-hydroxytryptamine in venom serves any biologically useful purpose. It can undoubtedly contribute largely to the pain caused by a scorpion sting (Adam and Smith, unpublished observations) and this has been suggested as being of survival value (cf. Collier[5]). Nevertheless, *B. minax* seems capable of surviving well enough though its venom has the reputation of being less toxic to man than is that of *L. quinquestriatus*, and this may well be attributed partly to the lower content of 5-hydroxytryptamine and partly to the fact that *minax* is a smaller scorpion and has a smaller quantity of venom at its disposal. However, the various current hypotheses of the normal function of 5-hydroxytryptamine, which include a possible neurohumoral role in some invertebrates and an action as a central transmitter in mammals (cf. Page[6]), tend to persuade one that the presence of 5-hydroxytryptamine in venoms is not entirely fortuitous.

In a previous paper[2], it was reported that cells of venom glands of *L. quinquestriatus* did not always show clearly positive enterochromaffin reactions[7]. In the present work all the typical enterochromaffin reactions were found to be strongly positive. A possible explanation for these differences may be that the production of 5-hydroxytryptamine by the venom glands varies at different times of the year. However, such a variation in the 5-hydroxytryptamine content of the venom could not be found since estimations of it were carried out on venom which was collected and pooled over periods of several months. The sections of *B. minax* and *L. quinquestriatus* glands were made at the same time of the year and treated simultaneously, and therefore, from this point of view, comparison is valid. Only faintly positive results to the enterochromaffin reactions were obtained with *B. minax* sections. This correlates well with the contrast in 5-hydroxytryptamine contents of the respective venoms and adds further weight to the concept that cells showing enterochromaffin reactions are producers or storers of 5-hydroxytryptamine.

The indole reaction is much less specific ; but in this case the strongly positive result obtained with *L. quinquestriatus* sections probably indicates that the reaction occurred with 5-hydroxytryptamine or its precursors, since a very weak reaction was seen in sections of *B. minax*, and since the other constituents of the two venoms seem to be similar (Adam and Weiss, unpublished observations).

An Effect of Insulin on Peptide Synthesis independent of Glucose or Amino-Acid Transport

Insulin enhances incorporation of amino-acids labelled with carbon-14 into protein of isolated rat diaphragms independent of its action in facilitating entry of glucose[1–3]. Kipnis and Noall[4] report that in similar circumstances insulin increases the accumulation of ^{14}C-α-amino*iso*butyric acid, a non-utilizable amino-acid. If the rate of penetration of the utilizable labelled amino-acids is also increased by insulin, the result would be a rise in the radioactivity of the intracellular amino-acid pool. Then an apparent increase in the rate of incorporation could occur without an actual change in the rate of peptide synthesis. This possibility has now been tested. Increased transport does not account for the insulin-mediated increase in the incorporation of utilizable amino-acids.

The method adopted was to divorce penetration and incorporation by effecting amino-acid accumulation before adding insulin. The amino-acid labelled with carbon-14, instead of being added *in vitro*, was injected intraperitoneally into the diaphragm donor ; 10 min. later the rat was killed and the diaphragm removed and pre-soaked (at 0–5° C.) for 20 min. in 10 ml. of Krebs–Henseleit bicarbonate medium without glucose. Presoaking in a large volume of fluid allows equilibration of the extracellular glucose and amino-acids with that in the medium. One hemi-diaphragm was then gently blotted and transferred to a beaker containing 1 ml. of medium without glucose. The second hemi-diaphragm was placed in 10 per cent trichloracetic acid ; it served as a zero-time control. Incubation was for 2 hr. at 37° C. in a Dubnoff shaker. At the conclusion of the experiment the muscle protein was isolated and its radioactivity determined[2] ; this is a measure of incorporation of amino-acid into peptide linkages (that is, protein synthesis).

Four experiments were carried out ; representative results are given in Table 1. Insulin added *in vitro* (0·2 unit/ml.) leads to a large increase in the incorporation of DL-phenylalanine-3-^{14}C and DL-histidine-2-^{14}C into muscle protein. This increase occurred despite accumulation of amino-acid having been effected before insulin was added and despite the absence of added glucose in the medium. The stimulation by insulin was larger than that obtainable when the amino-acid was added to the medium[3].

	Mean		34			69

The DL-phenylalanine-3-^{14}C (1·3 mc./m*M*) and the DL-histidine-2-^{14}C (1·0 mc./m*M*) were injected in 0·25 ml. of normal saline (1×10^7 c.p.m.). The control (no insulin) and experimental (insulin) groups were run simultaneously. The insulin (0·2 unit/ml.) was added *in vitro*. The results are expressed as c.p.m., corrected for self-absorption, per mgm. of protein isolated (usually 15–20 mgm.). Results in the zero column represent incorporation prior to the start of incubation as determined in one hemi-diaphragm; the 2-hr. column, results after the incubation period. The difference is the net increase in amino-acid incorporation during the experiment. *N.B.* In each experiment insulin mediates a large increase in amino-acid incorporation.

Control experiments demonstrated that only a small fraction of the labelled amino-acid incorporated either in the presence or absence of added insulin could have been derived from the extracellular fluid. The radioactivity in the Krebs–Henseleit medium in which the diaphragms were presoaked was determined. In one experiment with phenylalanine labelled with carbon-14 this was found to be 2,996 c.p.m./ml. of medium (range 2,610–3,310); in an experiment with labelled histidine it was 2,910 c.p.m./ml. of medium (range 2,638–3,239). The radioactivity in the Krebs–Henseleit medium is presumed to be in equilibrium with the extracellular fluid of the diaphragm, and this represents the maximum amount of radioactivity which can be carried over into the incubation medium. The wet weight of each hemi-diaphragm was approximately 100 mgm. (weight of the rats 110–130 gm.), and if we assume an extracellular space of 35 per cent of wet weight[5] the extracellular volume is 0·035 ml. We can now calculate that the radioactivity present in the extracellular fluid of the diaphragm is 105 c.p.m. (that is, 3,000 c.p.m./ml. × 0·035 ml.). The total observed increase in protein radioactivity in the phenylalanine experiment was 1,562 ± 114 (standard error) without insulin and 2,494 ± 127 with insulin; in the histidine experiment the values were 679 ± 47 and 1,336 ± 74 respectively. It is apparent that contamination of the extracellular fluid with administered labelled amino-acid could not account for the observed results.

We conclude from these preliminary results that insulin can influence protein synthesis at a locus distal to amino-acid penetration and independent of glucose entry.

Failure of Ribonucleoprotein to transfer Antibody Formation

Some data[1] indicate that templates for antibody synthesis consist of a ribonucleoprotein. Šterzl and Hrubešova[2], and Hrubešova *et al.*[3] have found that infant rabbits form antibodies when injected with nucleoproteins isolated from the spleen of immunized donors. However, they were not able to prove that those antibodies originated *de novo*.

Chickens are excellent producers of precipitins, and spleen forms antibodies at a high rate showing an increase in pentose nucleic acid and cells of the plasmocytic series[4]. On the other hand, Coombs's anti-human globulin test has proved to be extremely sensitive in detection of Rh antibodies. The present work combines these data in an investigation of the capability of ribonucleoprotein from an antibody-producing tissue to provoke antibody formation when transferred into infant chicks. This preliminary communication represents only one part of the results obtained.

Fifty Rhode Island Red pullets and infant chicks were used in the experiments. Adult chicks were immunized with human γ-globulin[5], the spleens removed three days after the last injection of antigen and used as a source of ribonucleoprotein. The titres of anti-human globulin antibody in the sera of killed birds were 1/1,000–3,000, as determined by Coombs's technique, using O CDe/CDe red cells strongly sensitized in an anti-D serum. (The same sensitized red cells were used in Coombs's test throughout the experiments.) The preparation of ribonucleoprotein was as follows. Spleens were removed, decapsulated and quickly frozen. Cytoplasmic homogenate was prepared in 0·14 *M* saline (1 gm. tissue to 2 ml. saline), left at 0° C. for a period of 3 hr. and then spun in a refrigerated centrifuge at 3,000 r.p.m. for 20 min. to remove large particles. The supernatant was dialysed against redistilled water overnight. The proteins were precipitated by cold ethanol (−10° C.), centrifuged and redissolved in 0·14 *M* saline. The method of Lowry *et al.*[6] was used for protein determination, and the concentrations of ribonucleic acid and deoxyribonucleic acid were determined according to Mejbaum's[7] and Ceriotti's[8] methods respectively. Ultra-violet light absorptions were measured in a Beckman *DU* spectrophotometer. 1 ml. of ribonucleoprotein preparation contained 5·3 mgm. protein, 1·03 mgm. ribonucleic acid and 0·027 mgm. deoxyribonucleic acid.

No evidence for the detectable quantity of anti-human globulin antibody and human γ-globulin in the ribonucleoprotein preparation was obtained. The following methods were used: (*a*) the capillary precipitin method with varied final salt concentrations[9]; (*b*) a modification of Ouchterlony's double-diffusion agar precipitin technique[10]; (*c*) the inhibition effect of ribonucleoprotein on an anti-human globulin serum with a low titre of specific antibody; (*d*) the Coombs's test performed with different dilutions of ribonucleoprotein complex; (*e*) examination for anti-human globulin antibody in the sera of six-month-old chicks which had received subcutaneously several injections of ribonucleoprotein.

One group of birds received intraperitoneally 2 ml. of ribonucleoprotein on the fifth day, and the second group on the twelfth day of post-embryonic life. The animals were bled on the first, third, sixth and tenth day later, and Coombs's tube technique was performed for detection of anti-human globulin antibody in chick sera. Each serum was used in different dilutions against a series of differently sensitized red cells. The following controls were set up: (*a*) Coombs's test with infant chick sera obtained prior to injection of ribonucleoprotein; (*b*) Coombs's test and capillary precipitin reaction performed with sera of infant chicks which had been treated with human γ-globulin (10-day-old chicks received four injections of 16 mgm. globulin during a period of 12 days); (*c*) Coombs's test with sera from adult chicks which had been intravenously injected with ribonucleoprotein (the heteroagglutinins for human red cells were removed by absorption).

All results obtained with the sera from treated infant and adult chicks were negative, showing no presence of circulating anti-human globulin antibody. The temporary unresponsiveness of chick infants to human γ-globulin (control *b*) is probably due to the immunological and protein-synthesizing immaturity of those cells which would later be responsible for production of antibodies. It seems, however, that the failure of ribonucleoprotein to induce the formation of antibodies in infant (test groups) and adult (control *c*) recipients also concerns the catabolic rate of ribonucleic acid when injected into animals of the same species. This facet of the problem was partly investigated by the method of Rabinovitch and Dohi[11] for the detection of serum ribonuclease, and the presence of this enzyme in the sera of treated infant and adult birds was established. This represents, of course, only indirect evidence for the interference of ribonuclease. But, since the integrity of ribonucleic acid is essential for protein synthesis[12], this possibility should be taken into account. Mention should also be made of the fact that the present work deals with cytoplasmic ribonucleic acid, and that different results may probably be obtained with nuclear ribonucleic acid owing to its higher specific activity[13]. Finally, whatever the correct interpretation might be, more observations are obviously needed about the fate of the isolated ribonucleoprotein and ribonucleic acid when injected into animals, and about the ability of molecules of ribonucleoprotein and ribonucleic acids to be incorporated by protein-synthesizing mechanisms of the recipient. It might be added that, in this respect, one is faced with essentially different situations when working with intact antibody-producing cells.

Neurosecretion and Intestinal Proteinase Activity in an Insect, *Calliphora erythrocephala* Meig.

SOME years ago it was suggested that the medial neurosecretory cells of the brain of *Calliphora erythrocephala* in some way influence protein metabolism, and especially the synthesis of protein. This hypothesis was based on the fact that in females deprived of these cells, the ovaries, accessory glands, corpora allata and œnocytes, organs which normally increase considerably in size during the early period of adult life, developed to a limited extent only although the flies were given an adequate diet of meat, sugar and water[1,2]. Furthermore, in flies fed on sugar and water only, but no meat, the organs mentioned were very nearly the same size as in females deprived of their medial neurosecretory cells. Therefore it seemed likely that in the absence of the hormone from the medial neurosecretory cells for some unknown reason the fly was unable to utilize the ingested meat. Observations proved that the flies did in fact eat some of the meat offered to them.

Transport of neurosecretory material in the two nervi œsophagei, which pass from the corpus cardiacum + ganglion hypocerebrale to the intestine, was described earlier[3,4]. This neurosecretory material is probably produced by the medial neurosecretory cells. Cutting the nerves caused a definite retardation of the growth of the ovaries[1]. These observations suggest an influence of the medial neurosecretory cells on digestion. This possibility was tested in experiments reported here.

For the determination of the proteinase activity of the gut we used the colorimetric method of Day and Powning[5], originally described by Charney and Tomarelli[6], but the homogenates were kept for four hours in the incubator instead of one. According to this method the intestines were ground in small tubes with clean sand which had been moistened with a glycerin–phosphate buffer mixture[7]. After homogenization, which was performed at room temperature, the volume of fluid in each tube was made up to 1 ml. with buffer solution. The tubes were kept overnight in the refrigerator. The flies used were females deprived of their medial neurosecretory cells when 5–8 hr. old (25° C.), operated controls[1], and normal, that is, unoperated controls. After the operation the flies were kept for 5 days at 25° C. and fed on meat, sugar and water. Some determinations were made on females fed only on sugar and water for 5 days, called sugar-flies.

Wigglesworth[8] found the proteinase activity of the midgut of *Calliphora* to be very weak as compared with that of *Glossina*. Apart from the sugar-flies our flies were given fresh meat for 2 hr. before the intestines were removed, and they were not starved before they had this last meal. Only the abdominal portion of the midgut was used for the determinations, and it was recorded whether or not the flies had eaten some of the fresh meat. The midguts were dissected 2½–6½ hr. after the beginning of the last meal. Probably we would have obtained higher values if the determinations had been undertaken some hours later[9]. As the determinations were made on homogenates of the midguts, the enzymatic activity of both the intestinal content and the intestinal cells was measured. The values are calculated per midgut, and not by weight of midgut, because in starved, normal flies with an empty gut the values were

Table 1. PROTEINASE ACTIVITY PER MIDGUT OF FEMALES DEPRIVED OF THEIR MEDIAL NEUROSECRETORY CELLS, OPERATED CONTROLS, NORMAL (UNOPERATED) CONTROLS AND SUGAR-FLIES. FIVE DAYS OLD AT 25° C. A MATURE EGG IS ABOUT 1·45 MM. LONG

Deprived of medial neurosecretory cells		Operated controls		Normal controls		Sugar-flies

1·9	0·15			15·0	½ mature	1·9	0·10
2·7	0·15						

found to be of the same order as in flies lacking medial neurosecretory cells.

Formerly it was found that in females deprived of their medial neurosecretory cells the length of the biggest egg-chamber never exceeded 0·17 mm., and therefore the size of the longest egg-chamber was used as a control on the removal of the cells. The stage of development of the ovaries of the operated and normal controls and of the sugar-flies was also noted.

The proteinase activity in the four categories of flies is given in Table 1. Apart from two normal controls with fully mature ovaries, the midguts of the operated controls and those of the normal controls had a much higher proteinase activity than the midguts of the flies deprived of medial neurosecretory cells. As the midguts of most of the flies contained meat, the figures do not merely give the values of the proteinase activity of the intestine itself but also the activity of the intracellular proteinases of the meat, but whatever its size it should be the same in all sets of animals.

In *Aedes aegypti* Shambough[10] found a pronounced correlation between the amount of ingested blood and the proteinase activity. So far it has not been determined whether blow-flies deprived of medial neurosecretory cells eat less meat than the controls. But even if there is a similar correlation in the normal *Calliphora* as in *Aedes*, this does not seem to apply to flies deprived of medial neurosecretory cells, because these flies, in spite of having ingested meat, do not show a higher proteinase activity than the sugar-flies. The speed at which the food travels through the intestine[11] might also be a significant factor.

As proteinases are themselves proteins, the production of proteinase by the intestinal cells can be regarded as the protein synthesis of these cells, and so the result of this investigation seems to support the view that the hormone from the medial neurosecretory cells has an influence on the protein metabolism, and especially on the synthesis of protein. If *Calliphora* without medial neurosecretory cells is able neither to break down nor build up protein, it is easy to understand why the removal of the cells produced a result in a 100 per cent of the flies. It also explains the small variation in the size of the growing organs[1].

As pointed out earlier[1] the flies deprived of medial neurosecretory cells are able to utilize the specific protein of the larval fat-body, part of which is carried over into the adult stage where it is used for the small initial growth of the organs which do grow in the adult (see above). This fact seems to agree with our interpretation of the function of the neurohormone. Welsh and Travis[12] have substantiated the view that another neurohormone, namely, the neurohumor acetylcholine in Planaria, is involved in growth and tissue maintenance.

As yet we do not know whether the effect of the neurohormone on the production of intestinal proteinase is a direct or an indirect one. The investigation is being continued, and a more detailed account of the experiments will be published elsewhere.

It is a pleasure to thank Prof. H. Holter for valuable discussions. We also wish to thank the Carlsberg Foundation, which has supported this work with a grant.

Utilization of Inorganic Sulphate by Baker's Yeast

IT has been established by a number of authors that sulphate is the usual source of sulphur for many micro-organisms, and also for yeasts[1]. However, much remains to be elucidated about the details of sulphate uptake by the cell and its metabolism.

We have examined the conditions of transport of sulphate into *Saccharomyces cerevisiae* and the effect of several other sulphur-containing compounds thereon. Throughout the work, washed baker's yeast was used, which was shaken for 5 hr. in an inorganic

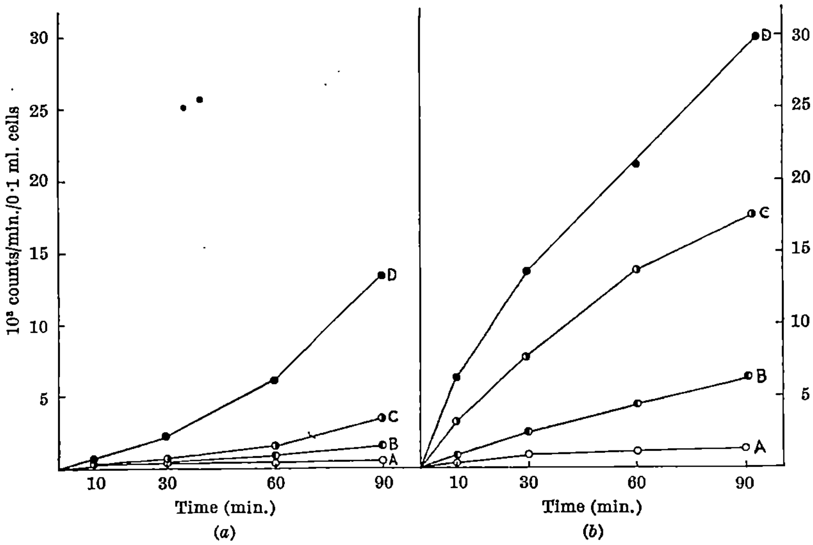

Fig. 1. Incorporation of radioactive sulphate in a nitrogen-deficient (left) and a sulphur-deficient (right) yeast. Incubation in air at 22°. *A*, Medium without glucose and ammonium chloride; *B*, medium without glucose; *C*, medium without ammonium chloride; *D*, complete medium

salt medium enriched with yeast extract; from the complete medium either ammonium chloride or potassium sulphate was omitted and thus nitrogen-deficient and sulphur-deficient yeast were obtained, respectively. Incubation of the washed yeast was then carried out aerobically at 22° in the same inorganic medium but without yeast extract and with ammonium chloride or glucose or both omitted as required. An osmotically insignificant amount of $^{35}SO_4^{2-}$ was added to trace the incorporation of sulphur into various yeast components. Samples of the suspension were centrifuged at 0°, washed with ice-cold water and aliquots used for determining the total radioactivity of cells and the radioactivity of the supernatant after hydrolysis of the cells in 5 *N* hydrochloric acid, removal of inorganic sulphate by precipitation with barium chloride and chromatography in butanol–acetic acid. No loss of radioactivity occurred during the washing procedure at 0°.

It follows from Fig. 1 that both glucose and ammonia are required for the maximum uptake of sulphate from the medium; thus both simple diffusion and active transport of sulphate into the cells appears unlikely. In nitrogen-deficient yeast a source of nitrogen in the medium is of decisive importance for the incorporation of sulphur-35 to occur, which is in agreement with the finding[2] that such yeast has its metabolic pool of nitrogen exhausted. On the other hand, in sulphur-deficient cells the nitrogen content is probably increased (*inter alia* due to depletion of glutathion sulphur, cf. ref. 3 for *E. coli*) and thus on adding sulphate to the medium sulphur-containing compounds may be formed without any exogenous source of nitrogen. Moreover, the lack of sulphur in the latter yeast brings about a more rapid uptake of radioactive sulphate. The steeper slope of curves *C* and *D* in both graphs is caused also by an actual increase in yeast dry solid (mainly polysaccharides under our experimental conditions). Essentially the same results were obtained by estimation of the decrease of sulphate content in the medium by chemical methods.

It was shown afterwards that at 0° no uptake of sulphate by the cells occurs. On varying the concentration of sulphate in the medium between 0·4 m*M* and 2·0 m*M* no change in the rate of sulphate uptake can be observed for the first hour of aerobic incubation of nitrogen-deficient yeast. These results also make simple diffusion of sulphate into the cell very unlikely.

Table 1. EFFECT OF SULPHUR-CONTAINING COMPOUNDS* ON INCORPORATION OF $^{35}SO_4^{2-}$

Compound added	Inhibition (per cent)	
	N-deficient yeast	S-deficient yeast
Na_2SO_3	58	38
$Na_2S_2O_3$	44	30
Thioglycollic acid	15	8
Cysteine	37	18
Methionine	16	8

* In each case 750 μgm. sulphur/10 ml. of medium was added

The effect of sulphur-containing compounds on incorporation of radioactive sulphate during aerobic incubation in a complete medium at 22° is shown in Table 1.

The Lineweaver–Burk plot of a kinetic measurement of sulphite and thiosulphate inhibition with sulphur-deficient yeast indicates that thiosulphate acts as a competitive inhibitor of sulphate uptake; sulphite, however, behaves somewhat anomalously at concentrations greater than 1 m*M* (cf. ref. 4). The generally higher inhibition in nitrogen-deficient yeast points to a more pronounced metabolic character of sulphur incorporation in such yeast; the details, however, are being studied at present.

The distribution of activity in amino-acids is rather complex, the general observation being only that methionine becomes active later in the course of incubation than cysteine. It appears from the results that most of the sulphate is not taken up as such by the yeast but rather in connexion with some nitrogenous carrier (for example, 3′-phospho-adenosine-5′-phosphosulphate[5]) and then metabolized further.

A detailed study of the effect of anaerobiosis and of inhibitors at various concentrations, particularly on individual amino-acids, is being concluded and will be published elsewhere.

An Effect of Yeast Extract on the Growth of *Chlorella*

Chlorella vulgaris (Pearsall's strain) grows well on glucose in darkness[1]. Recently, in this laboratory, we tried to grow this alga on glucose in darkness in an atmosphere free from carbon dioxide. The attempt was unsuccessful; presumably carbon dioxide fixation is essential in at least one of the reactions necessary for growth. Since it has been reported that the requirement for carbon dioxide by *Neisseria gonorrhoeae* can be replaced by a supplement of yeast extract[2], the effect of adding yeast extract to the *Chlorella* cultures was investigated.

Pure cultures of *Chlorella* were grown in 50-ml. Erlenmeyer flasks in a mineral salts medium[3] containing 0·5 per cent glucose and 'Difco Bacto' yeast extract in the required concentration. The flasks contained a centre well, in which sodium hydroxide and filter paper were placed to remove carbon dioxide, and were closed by vaccine stoppers. The cultures were shaken at 25° C. in darkness. Growth was estimated by counting the cells four days after inoculation; it was expressed as a percentage of the growth in the cultures with glucose, no yeast extract and an atmosphere of air.

It was found that the addition of yeast extract did, in fact, allow some growth in a carbon dioxide-free atmosphere (Fig. 1); but the more striking effect of yeast extract was the inhibition of growth in an atmosphere of air. The growth of *Chlorella* on glucose in darkness, in air, was reduced by one-half by yeast extract in a final concentration of only 0·01 per cent. The inhibition was just as pronounced when the yeast extract was sterilized by Seitz filter and added to the autoclaved medium. The constituent of the yeast extract which inhibits growth is unknown. Organic acids inhibit the growth of *Chlorella* by combining with iron[4]. The possibility that a constituent of yeast extract acted in this way was tested by adding additional iron to the medium, but it had no effect on the inhibition.

It is of interest that a related, but colourless, alga, *Prototheca zopfii*, requires thiamine for growth[5] and, in fact, grows well in the *Chlorella* mineral medium with the addition of 1 per cent glucose and 1 per cent yeast extract. Removal of carbon dioxide from the atmosphere has little effect on the growth of *Prototheca* in this medium or when $10^{-5} M$ thiamine is substituted for the yeast extract (Table 1). This suggests either that *Prototheca* has a much lower carbon dioxide requirement for growth than *Chlorella*, or that thiamine can replace this requirement. However, the addition of $10^{-5} M$ thiamine to *Chlorella* cultures did not allow growth in a carbon dioxide-free atmosphere.

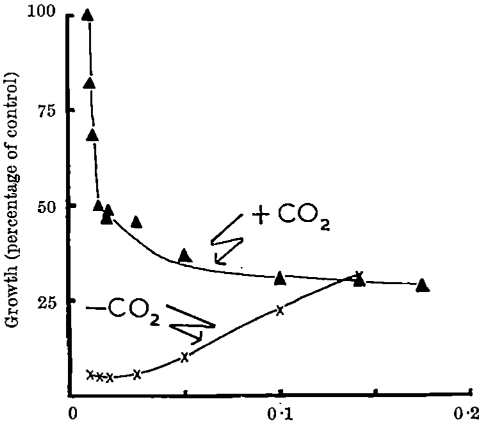

Fig. 1. The effect of yeast extract on the growth of *Chlorella vulgaris*. All cultures contained 0·5 per cent glucose and were shaken in darkness. The carbon dioxide-free cultures contained sodium hydroxide in centre wells of the flasks. Growth is expressed as a percentage of that in the flask with glucose, no yeast extract and an atmosphere of air

Table 1. GROWTH OF *Chlorella* AND *Prototheca* WITH AND WITHOUT CARBON DIOXIDE IN THE ATMOSPHERE

	Cells/c.mm.			
	Chlorella vulgaris (Pearsall's strain)		*Prototheca zopfii* (Beijerinck's strain)	
	+ CO_2	− CO_2	+ CO_2	− CO_2
No addition	12,320 (100%)	2,960 (24%)	—	—
1 per cent yeast extract	4,176 (34%)	3,430 (28%)	12,400 (100%)	12,501 (101%)
10^{-5} Thiamine	20,760 (168%)	3,135 (25%)	10,310 (83%)	11,500 (93%)
Inoculum	863 (7%)		79 (0·6%)	

Each flask contained 10 ml. of *Chlorella* mineral medium with 1 per cent glucose added and the other additions indicated. After inoculation the flasks were shaken in the dark at 25° C. in a Warburg tank. The carbon dioxide-free cultures contained sodium hydroxide in centre wells.

Isolation of *l*-Quinic Acid in Citrus Fruit

THE organic acids in citrus juices are chiefly citric and malic, although tartaric and oxalic acids also have been reported in grapefruit[1]. In our laboratory, succinic acid was found in frozen mature oranges. Wolf[2] isolated citric, malic and an unidentified acid from citrus fruit. Sinclair and Eny[3] reported that in the peel malic acid predominates while citric and oxalic acids occur in smaller amounts.

In a study of organic acids in citrus fruit using the gradient elution technique on a 'Dowex-1' column, an unknown acid with an R_{malic} of 0·56 was detected in both the peel and juice. This acid alone or with authentic quinic acid was eluted from the column in the same fractions as quinic acid, and gave a positive test with the Cartwright and Roberts[4] reagent. The presence of *l*-quinic acid has been reported in apples[5] and peaches[6].

The quinic acid was first isolated from 1,600 gm. of immature Valencia orange peel using an ion-exchange resin, 'Dowex-1 × 8', of 200–400 mesh packed in a 2·3 cm. × 25 cm. column. The macerated peel was extracted three times with 60 per cent ethanol which was then evaporated under reduced pressure. The remaining aqueous solution was treated with charcoal, filtered, and first passed through a column of 'Dowex-50' ion-exchange resin and then through a column of 'Dowex-1' in the acetate form. This column was washed with distilled water, and the acid was eluted according to the gradient elution method of Hulme and Wooltorton[7] with a slight modification. The change consisted of using a 500-ml. mixing flask filled with water and gradually adding 2 N acetic acid during the elution. Fractions of 20 ml. were collected at 40 ml./hr. with a mechanical fraction collector. Each fraction was chromatographed on Whatman No. 1 paper with butanol–acetic acid–water (4 : 1 : 5). Quinic acid was detected with the Cartwright–Roberts[4] spray reagent in fractions 12 to 22, which were combined and evaporated to near dryness under reduced pressure. The residue was dissolved in 100 ml. of ethanol and precipitated by adding 4 vol. of ethyl ether. The crude quinic acid (2·5 gm.) recrystallized twice from ethanol produced 1·5 gm. of pure material. Apart from its chromatographic properties similar to quinic acid, the isolated compound had a melting point of 162° C. (ref. 8, 162° C.), which was not depressed when mixed with authentic quinic acid : $[\alpha]_D^{23} = -43°$ (ref. 8, $[\alpha]_D^{20} = -44°$) ; neutralizing equivalent, 195. Infra-red absorption was also similar to that of an authentic sample of quinic acid.

Table 1. QUINIC ACID IN MATURE CITRUS FRUIT

Variety and type of citrus fruit	Peel (mgm./100 gm. fresh weight)	Flesh (mgm./100 gm. fresh weight)
Pineapple orange	172	52
Marsh grapefruit	233	87
Dancy tangerine	206	27
Corregia lemon	161	18
Persian lime	209	146

Amounts of quinic acid present in the peel and flesh of mature fruit of several citrus varieties are given in Table 1. The quinic acid was determined by titration after elution from the column and complete removal of the acetic acid[7]. Results for the proportions of quinic acid relative to the other organic acids in citrus fruits will be published in due course.

This work was carried out in co-operation with the Florida Citrus Commission, Lakeland, Florida.

BIOLOGY

Old and New Solutions to the Eel Problem

THE ingenious hypothesis proposed by Dr. D. W. Tucker[1] to explain the complex problems of the biology of the European eel presents in my opinion some heavy difficulties. I believe it therefore necessary to offer some observations with the intention of clarifying the question.

(1) When the European eel descends to the sea as a silver eel it does not show "a profound degeneration of the gut". The occlusion of the vent observed by Schnakenbeck[2] is, according to my experience, an entirely exceptional occurrence. All the silver eels I have examined had a gut of normal structure, although small in volume[3]. Silver eels kept in aquaria are indeed able to take up food again, although they are not so voracious as the yellow eels.

Survival and re-feeding of silver eels is not followed by regression of the gonads. Regressive pictures are frequently observed in the eels' gonads, even in the yellow eels ; but this is a cytological phenomenon that does not affect the whole gonad as an organ[4].

The whole organization of the descending eel does not present any indication of nearing death. Changes in colour and structure of the teguments, eye enlargement, transformation of retinal pigments[5], functional activation of the endocrine system are all conditions suggesting that when silver eels are going to live in deep marine waters they are still endowed with an intense vitality.

(2) On the basis of Schmidt's[6] results, it seems that European and American eels spawn in two slightly displaced areas ; but we cannot exclude the possibility that these areas are coincident. In any event there is no evidence sufficient to support the idea that a temperature difference of a few degrees would be enough to induce two sets of genetically homogeneous larvæ to acquire such different numbers of myomeres as 103–111 (average 107·2) for *Anguilla rostrata* and 110–119 (average 114·7) for *A. anguilla*. Even in the youngest larvæ or prelarvæ, there are clearly discrete myomere numbers[7], and to admit such a strong environmental influence would require the assumption that the eggs, from the beginning of their development, are separated into two completely isolated groups, one of which is carried in warmer, the other in cooler waters, without intermediate conditions. Hydrographic hypotheses do not seem to be sufficiently well founded to explain such a clear-cut separation of two variability curves of the myomere numbers as observed by Schmidt[7] between the larvæ of the American and the European eel.

The differentiation in the myomere numbers occurs in any event too early to be related to the influence of the Atlantic currents with their different temperatures. In the spawning area there are no sharp limits between cold and warm superficial waters, but a gradual variation from south to north of only 4 deg. C.

It is true that there are still a number of difficulties in explaining the life-history of the eel. It is particularly difficult to prove that all the Mediterranean eels are compelled to go out to the Atlantic. However, the fact that we are not able to capture them in the Strait of Gibraltar is not decisive evidence against such a migration.

The biology of the eel is certainly one of the most puzzling problems in marine biology, but the interpretation proposed by Dr. Tucker requires so many new hypotheses that it is too difficult to accept it on the basis of present knowledge.

UMBERTO D'ANCONA

Zoological Department,
University, Padua.

[6] Schmidt, J., "Danish Eel Investigations" (Copenhagen, 1932).

[7] Schmidt, J., *Phil. Trans. Roy. Soc.*, B, **211**, 179 (1922).

Prof. D'Ancona's objections are mainly due to misunderstanding and are met by my original paper[1], where not directly by a necessarily condensed text, implicitly through the literature cited.

(1) His divergent assessment of the silver eel depends upon his experience being confined to eels in the early stages of transformation. Schnakenbeck[2] and Berndt[3] have described autolysis and phagocytosis of the gut tissue by tissue, while Bertin[4] concludes his readily available (and illustrated) summary of their work by remarking: "Such, broadly, is the state of dilapidation to which the digestive tubes of the silver eel are reduced".

The occlusion of the vent reported by Schnakenbeck[2] in a North Sea specimen was not represented as other than a unique observation. But the condition of this eel, with its normal genital papilla, has been accepted as a typical and non-pathological continuation of a process the later stages of which are generally concealed from our study and is to be taken as representing the state attained in European continental waters by eels which survive thus far.

My remarks concerning regression of the gonad were intended to refer to cytological, physiological and metabolic phenomena rather than to gross morphology.

The whole point of my comparative discussion of the American and European migratory eels was that the advanced modifications of the European eel appear to be ill-adapted to the time-table of a presumed return journey. We may indeed know that a motorist is in the best of health but, as we watch him driving down a mountain road, intoxicated and without brakes, we can still legitimately say that his celebration was premature and that he is unlikely to reach his destination.

(2) Here I must ask Prof. D'Ancona to re-read my original paper. I did, in fact, suggest that the temperature conditions over the spawning-area of the eels admitted of the possibility of environmental determination of the somite-numbers; the suggestion stands as a hypothesis, not as an alleged fact or dogma, and its further treatment appears to be a matter for observation and experiment rather than for mere expressions of opinion. Prof. D'Ancona's remark about the "gradual variation . . . of only 4 deg. C." confirms my belief that he has not appreciated the four-dimensional nature of my argument.

I cannot agree that my interpretation requires the admission of many new hypotheses. It requires, admittedly, that a great deal of evidence which we have been accustomed to viewing in one familiar pattern must now be re-arranged into a drastically new one. But, as I showed in a comparison of Schmidt's ideas and my own, I make only one unfounded assumption: that the eel somite-numbers may be affected by temperature in the same way as those of numerous other fishes. The basic idea, once grasped, is so simple that anticipation was a constant fear while the paper was in preparation. Whether it is ingenious, or merely ingenuous, must, in the absence of any more convincing citation of available evidence, be a matter now for research rather than for philosophical speculation.

Two further points may be mentioned which have recently come to hand. First, Carlisle and Denton[5] have shown that in the metamorphosis of the visual pigments, as in several other characters already discussed[1], the European silver eel is more advanced than the American eel. Secondly, Dr. Winifred E. Frost has kindly brought to my attention a paper[6] on the age and length of the American eel.

Number of Fibres in the Optic Nerve and the Number of Ganglion Cells in the Retina of Anurans

Using a light microscope, Bruesh and Arey[1] found that there were about 15,300 myelinated and 13,700 unmyelinated fibres in the optic nerve of the frog (*Rana pipiens*), and about 10,200 myelinated and 5,500 unmyelinated fibres in the optic nerve of the toad (*Bufo americanus*). However, in my electron microscope study of the optic nerve of these and other Anurans (*Rana catesbeiana*, *Bufo terrestris* and *Hyla cinerea*) I have found[2] that the unmedullated axons are in a considerably larger number, having been underestimated by a factor of 30 or more, and that most of them could not have been resolved with the light microscope. My observations, though, do not greatly contradict the earlier numbers of myelinated fibres, for these can be counted with reasonable accuracy after myelin stain. In the present communication I only wish to report about the general arrangement of the unmyelinated axons and their number. The full description of the fine anatomy of the optic nerve is deferred to an extensive article now in preparation.

Optic nerves were fixed in buffered (*p*H 7·4) osmium tetroxide and embedded in methacrylate. In all species studied, the unmyelinated axons are 0·15–0·6μ in diameter, and under the electron microscope appear in bundles of many closely packed axons, surrounded by glial cell expansions and myelinated fibres (Fig. 1). No glial cell intrudes between the unmyelinated axons of a bundle, and they remain separated from each other only by a gap of extracellular space 100–200 A. wide; a similar gap separates the unmyelinated axons from the surrounding glia or adjacent myelinated fibres. This space is continuous with that between the glial membranes which form mesaxons. Due to such close packing, the unmyelinated fibres cannot be adequately resolved with the light microscope, for while most of the unmedullated axons are within the limits of resolution of this instrument, the distances which separate them are very much less.

Both under light and electron microscopy, myelinated and unmyelinated fibres appear (in the gross) uniformly distributed across the nerve, with no sign of regional differences in density of one or the other. In these circumstances the number of unmyelinated axons can be calculated by multiplying the ratio of unmyelinated to myelinated fibres by the number of medullated axons counted in myelin-stained material. Random sampling in a cross-section of a nerve gave a ratio of 31/1 (*S.E.* = 3) unmyelinated to myelinated axons in the frog (*Rana pipiens*). The different field samples varied between ratios of 21/1 and 57/1; a total of about 4,000 fibres were thus counted in fifteen fields. A similar procedure gave a ratio of

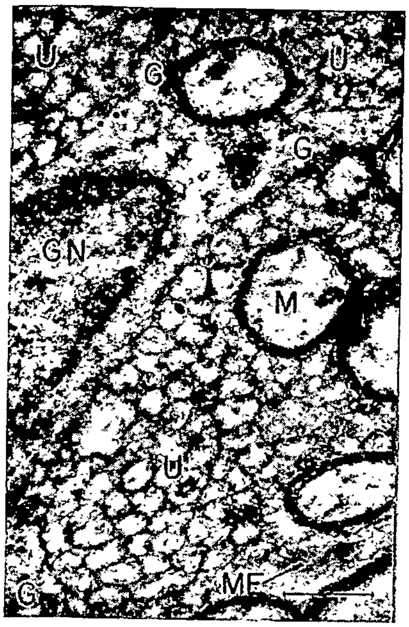

Fig. 1. Electron micrograph of a transverse section of the optic nerve (*Rana catesbeiana*). Fixation with buffered (*p*H 7·4) osmium tetroxide and methacrylate embedding. Notice the closed circular profiles which correspond to transverse sections of unmyelinated axons (*U*). Notice their relations with neighbouring glial cells (*G*) and myelinated fibres (*M*). *GN*, glial nucleus; *ME*, mesaxon. Scale 1μ

about 30/1 (*S.E.* = 3) unmyelinated to myelinated fibres in the toad (*Bufo americanus*), with ratios which varied from 15/1 to 53/1 in the different fields. About three thousand axons were counted in twelve fields. Using Bruesh and Arey's counts of medullated fibres, there would appear to be about 470,000 unmyelinated axons in the frog, and about 320,000 in the toad.

By means of degeneration experiments it can be shown that most of, if not all, the non-medullated axons are of retinal origin. Simply on the basis of numbers they must arise for the most part from ganglion cells 7–10μ in diameter present in the retina. Due to their small size, cells like these have been usually considered as glia[3]; but that they really are ganglion cells can be shown in retinas stained with methylene blue. There the axons and dendrites are revealed. Counts in three eyes of *Rana pipiens* show about 440,000 of these small ganglion cells in each retina. Larger ganglion cells, mostly 14–20μ in body diameter, number about 12,000; they most probably give rise to the larger myelinated axons. In any event, the partition of small and large ganglion cells in the retina follows that of myelinated and unmyelinated axons in the nerve. In these counts I used the Abercrombie[4] method for counting nuclei in microtome sections; 10 per cent of the total population of ganglion cells was actually counted. The discrepancy in the number of axons in the nerve and ganglion cells in the retina is at least partly due to the presence of myelinated efferent fibres[5], and may also be due partly to the existence of unmyelinated efferent axons.

The results presented here show that nerve fibres in the optic nerve of Anurans cannot be accurately counted under the light microscope, and that electron microscopy is required to reveal fully the unmyelinated axons. A similar revision may be needed in the estimates of fibres and retinal ganglion cells in the visual system of other vertebrates.

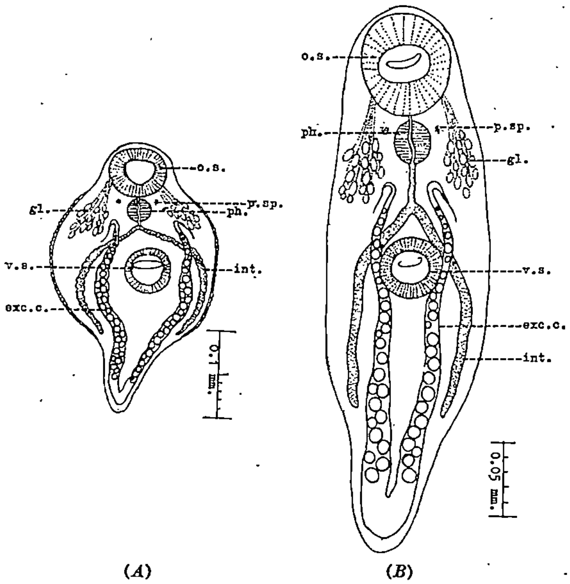
Metacercaria (Allocreadioidea) in the Planktonic Ctenophore, *Pleurobrachia globosa* Moser 1903, from the Madras Coast

Various marine invertebrates have been known to harbour cercariæ or metacercariæ of trematodes of fishes. Late cercariæ of *Opechona* (=*Pharyngora*) *bacillaris* were found in medusæ of *Obelia* sp., *Cosmetira pilosella*, *Turris pileata* and *Phialidium hemisphericum*, as well as in the ctenophore *Pleurobrachia pileus*, by Lebour[1] at Plymouth, and by Stunkard[2] (from the ctenophore only) at Roscoff, Finisterre. After a long interval, Franc[3] described the same metacercaria from *Phialidium hemisphericum* and *Pleurobrachia pileus* in France. There appears to be no other report of larval trematodes from ctenophores, although many other marine invertebrates, such as medusæ, siphonophores, copepods and chætognaths, have been described as their natural hosts by Poche[4], Martin[5], Dollfus, Anantaraman and Nair[6], and Dawes[7].

In the present communication, metacercariæ are reported from *Pleurobrachia globosa* collected from Madras inshore plankton. The rate of infection was 1–3 parasites in each of 8 of the 14 ctenophores examined. They were in an un-encysted condition and moved actively with the aid of the suckers when liberated from the gastric cavity of the hosts. Camera lucida drawings of a specimen in a contracted and an extended state were made (Fig. 1*A* and *B*).



(*A*) (*B*)

Fig. 1. Metacercaria from *Pleurobrachia globosa*: *A*, contracted; *B*, extended. Key: *exc.c.*, excretory canal; *gl.*, glands; *int.*, intestine; *o.s.*, oral sucker; *ph.*, pharynx; *p.sp.*, pigment spot; *v.s.*, ventral sucker

The larva is identified as a metacercaria, as it has no caudal appendage and reflects the adult condition except for the genitalia. The body is elongate, 0·390 mm. × 0·111 mm., broader in the anterior region, and covered with a thick non-spinous cuticle. The oral sucker is conspicuous and large, 0·058 mm. in diameter. The mouth leads to a muscular pharynx, 0·039 mm. × 0·020 mm., situated immediately behind the oral sucker, a pre-pharynx being practically absent. The short œsophagus bifurcates into the intestinal crura, which are broader than the œsophagus itself, and extend posteriorwards up to three-quarters of the length of the body. The ventral sucker is also circular, 0·039 mm. in diameter, and therefore smaller than the oral sucker. It is situated about the middle of the body behind the region where the œsophagus forks. Bundles of gland cells are present on the sides in the anterior region. There is a pair of faintly staining pigment spots, one on each side of the pharynx. The lateral excretory canals are very prominent, only slightly wavy, and are filled with large globules. They are continuous at the posterior end and open out through a short median stem. They become gradually narrower as they go forward and turn back in the œsophageal region. There is no distinct structure as an excretory bladder, and the excretory system therefore appears as an extended V with an insignificant median duct.

This metacercaria needs to be compared with the only one known from a ctenophore, namely, that of the Allocreadiid *Opechona bacillaris* described by Lebour[1], Stunkard[2] and Franc[3]. It differs from it in having wide lateral excretory canals forming a V-shaped pattern, glandular structures associated with the oral sucker and no pre-pharynx. Assuming that this metacercaria is also derived from a trichocercous cercaria, it should be considered as belonging to the ocellate group of marine trichocercous cercariæ, classified by Dollfus[8] together with that of *Opechona bacillaris* and others enumerated by Dawes[9]. Its adult may therefore be a trematode similar to the genus *Opechona* and parasitic in fish hosts which ingest ctenophores.

La Rue[10] has formulated a new system of classification of the Digenea on the basis of life-cycle patterns and larval morphology, providing a key to all the families. This approach will be of immense value in identifying larval trematodes the adults of which have not been related to them, and in solving the life-cycles of many of them. The present metacercaria falls under the super-family Allocreadioidea Nicoll 1934, as an ophthalmotrichocercous kind, and may belong to one of the seven families listed under it, namely, Acanthocolpidae Luhe 1909, Allocreadiidae Stossich 1903, Lepocreadiidae Nicoll 1934, Megaperidae Manter 1934, Monorchidae Odhner 1911, Opecoelidae Ozaki 1925 and Opistholebitidae Fukui 1929—most probably Allocreadiidae. Three hosts are usually involved in the life-cycle of the representatives of these families, and in the present case they could be the gastropod (or lamellibranch), the ctenophore (or medusa, copepod, or *Sagitta*), and the fish.

Pelagic organisms serve as food for marine vertebrates and should accordingly be expected to carry the larval stages of helminths developing to maturity in the latter. The examination of other representatives of the planktonic biota in the coast of Madras is being continued in the hope of discovering more of these larval helminths.

I gratefully acknowledge the guidance of Prof. C. P. Gnanamuthu in this investigation, which was begun during the tenure of a Government of India senior scholarship.

An Albino Specimen of the Common Frog

ON February 22, Mr. L. Gentry, of Blacksmith Hill, Sanderstead, Surrey, found an albino specimen of the common frog (*Rana temporaria*) in his garden. He presented the frog to this Museum, and it is now living in the Aquarium.

The frog is a male with the back and legs an evenly coloured yellow and the ventral surface a whiter tone. The thumb pads are a dark brown and the eyes a bright red.

It is hoped that this frog will breed with normal females, and various workers have agreed to hatch the spawn and rear the frogs with the view of trying to establish an albino strain.

Influence of Temperature on the Number of Vertebræ in Fish

THE number of vertebræ in fish is considered to vary with temperature during early development. From field observations, it is generally considered that fish subjected to low temperature tend to have more vertebræ than those in warmer waters. This was supported by the experiments of Gabriel[1] on *Fundulus heteroclitus*, of Dannevig[2] on *Pleuronectes platessa*, and of Kubo and Kobayashi[3] on *Oncorhynchus keta*. On the other hand, Tåning[4] showed that the lowest average number of vertebræ was obtained at an intermediate temperature, while both higher and lower temperatures produced a higher average in his experiment on *Salmo trutta trutta*. A similar result was obtained by Lindsey's[5] experiments on *Macropodus opercularis*. Thus the results of experimental studies are not consistent.

I reared eggs at different constant temperatures throughout the sensitive period from one pair of snake-head fish *Channa argus* (Cantor), and examined the vertebral number of the young fish of each group. The experiment was repeated three times using three different pairs. The results are given in Table 1.

From the results, it may be concluded that: an intermediate temperature produces a lower average number of vertebræ than either high or low temperature in *Channa argus*; genetic factors seem to have more effect on the number of vertebræ than environmental ones. The first conclusion does not coincide with the generally accepted view mentioned above, but coincides with the results of Tåning's and Lindsey's experiments.

Table 1. Distribution of Vertebral Numbers in *Channa argus* Raised at Different Constant Temperatures

Experiment	Raised at (° C.)	Number of vertebræ							Total number of fish examined	Average number of vertebræ	P
		56	57	58	59	60	61	62			
1	29·5	5	247	372	21				645	57·63	$P < 0·001$
	22·5	11	222	208	13				454	57·49	$P < 0·001$

Vibrio spp. in Finnock from the Aberdeenshire Dee

In August 1958 reports of dead finnock (young sea trout) were received from the fishermen operating sweep nets near the mouth of the River Dee. These fish were reported either to look quite healthy or to have some hæmorrhagic marks on the belly. A number of these fish were examined and the same organism was isolated, from all, in almost pure culture, on both nutrient agar and a sea-water agar. This organism has now been studied morphologically and biochemically and the results obtained indicate that it is a species of *Vibrio*.

Finnock from another river where there had been no noticeable mortality were inoculated with this organism. When the inoculation was intraperitoneal the fish died within six days when kept in fresh water. They showed no outward sign of disease, but yielded pure cultures of the organism from all the organs.

With subcutaneous inoculation the fish again died, within 48 hr., and the muscle around the site of the inoculation became hæmorrhagic, as in the specimens from the Dee, although this hæmorrhagic area did not show through the skin. Again pure cultures of the organism were obtained from the organs and the muscle. Although uninoculated finnock from the same source kept in fresh-water for four days and then in 50 per cent sea water for four days (to eliminate fungus) died due to a failure of the air supply, none of these yielded the *Vibrio*. The organism was found to grow more vigorously in sea-water media, so these fish can be considered as the controls.

A similar outbreak appears to have occurred in the Dee in 1957 when, unfortunately, only one fish was received for examination from a number reported dead. Similar organisms were isolated from this fish as also from an isolated finnock found dead in the Dee in 1954.

These outbreaks among finnock seem to be similar to those reported by Hoshina[1] in rainbow trout in Japan, where the infection was attributed to *V. piscium* var. *japonicus*. The latter is similar to the organism isolated from finnock. This disease may also occur in marine fish as Hotchkiss (personal communication) has found a similar organism which caused the death of many saithe near Shetland in 1949. The fact that *Vibrio* can infect both fresh-water and salt-water species is borne out by a summary of *Vibrio* species infections published recently by Rucker[2].

A fuller account of these investigations will be published elsewhere.

Marginal Growth of Leaves

Recently the marginal meristem of foliage leaves has been discussed by Pray[1] for monocotyledons and by me[2] for dicotyledons.

In dicotyledonous foliage leaves marginal and submarginal types of marginal growth can be recognized depending on the origin of the procambium[2]. The latter type may be subdivided into the adaxial (Fig. 1*D*), abaxial (Fig. 1*E*) and middle (Fig. 1*F*) types. In certain instances an intermediate condition between two types has been observed[3]. Except for some variegated leaves[4,5], *Daphne odora* is the only dicotyledon showing the marginal type of growth in its foliage leaves[2,6], development proceeding according to the pattern shown in Fig. 1*C*. Recent observations indicate that *Daphne pseudo-mezereum*

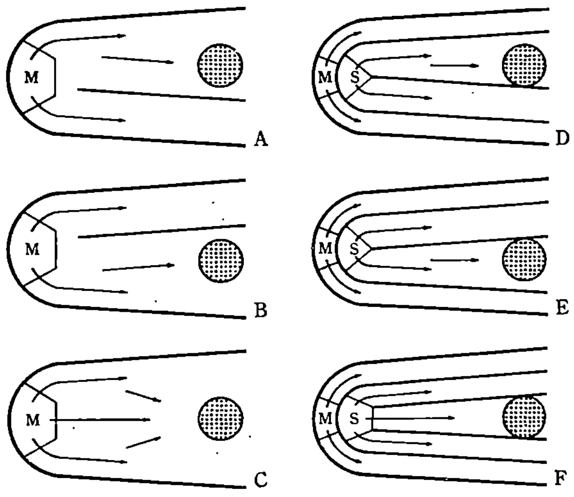

Fig. 1. Diagrams showing variations in activity of the marginal meristem of the leaf. The adaxial side is shown in the upper side of the figure. Stippled part is the procambium. *A–C*, marginal type; *D–F*, submarginal type *M*, marginal initial; *S*, submarginal initial

also shows a marginal type of development but follows the pattern shown in Fig. 1*A*.

I considered that the types of development recognized for dicotyledonous foliage leaves could also be applied to other categories such as scale leaves and monocotyledonous leaves which show marginal growth[3]. Observations of the scale leaf of *Rhododendron nipponicum* showed the marginal type of growth indicated in Fig. 1*A*. Foster[7] also reported the marginal type of development in the scale leaf of *Rhododendron*. Pray[1] did not see evidence of active periclinal divisions of marginal initials or protodermal cells in the leaf of *Philodendron*, which is classified as the type shown in Fig. 1*E*. However, Pray did find possible evidence of a periclinal division of a marginal initial, suggesting that this instance might possibly be classified as the type shown in Fig. 1*B*. Pray also described leaf development in *Hosta* where the pattern was that illustrated in Fig. 1*C*.

Thus, the subdivisions recognized in the submarginal type (Fig. 1*D–F*) may also be recognized in the marginal type (Fig. 1*A–C*). In many instances a fixed and unchangeable type of marginal growth during leaf development cannot be recognized in individual species; but it would appear that the type of marginal growth is diagnostic for each species if characteristic fluctuations in the ontogenetic process in general are considered.

I investigated phylogenetic correlations between the various types of marginal growth in one group—the Ericaceae and their allies[3]. Recently, however, variations in marginal growth have been reported for dicotyledons, monocotyledons and gymnosperms[1-3,8-10]. Interpretations of the relationships between the types in these groups will depend on more comprehensive investigations, both ontogenetically and phylogenetically, in seed plants or in vascular plants in general, including the ferns. The relationship between the marginal and submarginal types is particularly interesting. There may be direct correlations between the patterns seen in Fig. 1*A* and *D*, *B* and *E* and *C* and *F*. Possible evidence of this relationship is seen in *Rhododendron*. The scale leaf of *R. nipponicum* follows the pattern shown in Fig. 1*A* in its development; but other species of *Rhododendron* examined by me, and the Ericaceae in general, follow the pattern in Fig. 1*D*. Also the leaf of *Philodendron* suggests a pattern which is interpreted as being intermediate between that shown in Fig. 1*B* and that in Fig. 1*E*.

I wish to acknowledge my indebtedness to Dr. B. F. Palser, University of Chicago, for kindly going through this manuscript.

Regulation of Morphogenesis in an Oleaceous Tree, *Nyctanthes arbor-tristis*

The pioneers of biometry published many figures on the variation in flowers of numbers of petals, sepals, stigmatic bands, and so on. As they worked on herbs, they counted small numbers, and though they found differences in the means of different plants, were unable to compare the variances, either between plants or between the same plant at different times. *Nyctanthes arbor-tristis* Linn. (Oleaceae) sheds up to 1,492 flowers nightly, and up to 32,790 in a season, normally from September to early January in Calcutta.

Three trees of this species were observed throughout the season 1955–56 (ref. 1), and seventeen for seven weeks in 1957. Table 1 gives the grand total.

Table 1. Overall Frequency Distribution of Flowers (for Three Trees in 1955–56 and Seventeen Trees in 1957) according to Number of Petals

No. of petals	4	5	6	7	8	9	15	Total
No. of flowers	451	29,147	109,345	18,956	1,012	14	1	158,926

It will be seen that most flowers (68·8 per cent) had six petals. In 1957 the means for the seventeen trees ranged from 5·50 ± 0·0081 to 6·27 ± 0·0088. Most means differed significantly from all others. The means for three trees measured in successive years were 5·92, 5·89; 6·05, 6·09; and 5·98, 6·01. The differences were significant but small.

Fig. 1 shows the changes in the means for three trees during a season. In order to obtain a moderately smooth graph I took moving means over five consecutive days. It will be seen that for each tree the mean fell and then rose again.

The standard deviations also differed in the different trees, ranging from 0·5108 ± 0·0052 to 0·6605 ± 0·0069. Again many differences were highly significant. As, however, the usual test of significance for the difference of two variances is only valid when the distributions are normal, and the fourth moments are not very well determined, I tested the percentages of abnormality, that is to say, the percentages of flowers with a number of petals other than six. These often differed very significantly even when the means did not. The standard deviations increased systematically through a season as shown in Fig. 2, though for one of the trees they dropped on two occasions. The changes in means and standard

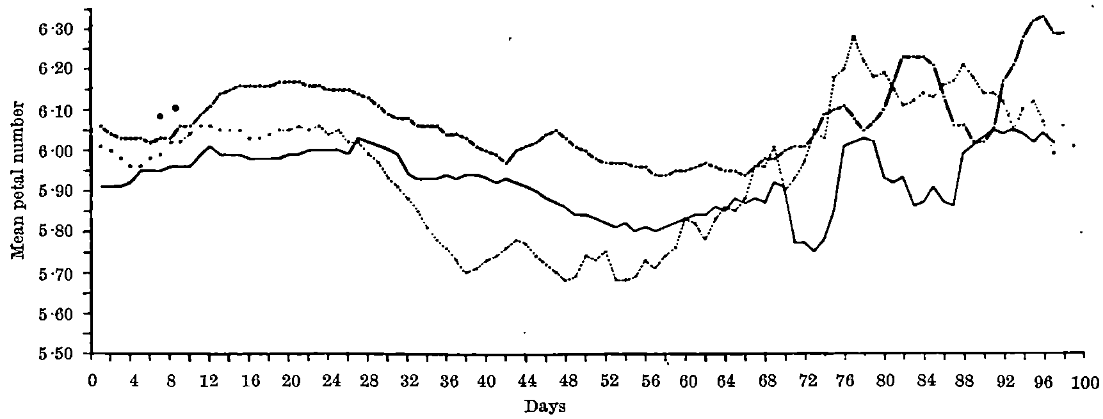

Fig. 1. Moving means of petal numbers over five consecutive days for three trees during the season 1955–56. ———, Tree No. 1; —·—·, tree No. 2; ...., tree No. 3

deviations alike are about 0·1–0·2. The point is that the means changed by about 2–4 per cent, and the standard deviations by 20–40 per cent or so.

If a craftsman produced articles with much the same mean dimensions in the course of a day's work, but their variance around this mean increased progressively, we should say that he was getting fatigued. It might be possible to trace this fatigue to a decline in the efficiency of 'negative feedback'. It is not so easy to apply this notion to a plant. The weather became progressively cooler during the flowering season, and the increased variance might be ascribed to this. However, I have observed the same increase in variance of petal number during the flowering season in two plants of each of *Jasminum pubescens* var. *alba* and *Jasminum pubescens* var. *rubescens*, although in these cases the temperature was rising. The closest analogy known to me is the case of pernicious anæmia in man. Here Price-Jones[2] showed that the mean diameters of red blood corpuscle increased moderately, but the standard deviation increased much more. Such words as regulation and homœostasis are applied to the processes by which such variables as body-temperature and blood glucose-level are kept relatively steady. Here we can measure the efficiency of regulation by the reciprocal of the variance in a set of successive values, and the regulation can be shown to depend on a negative feedback system. It may not be so easy to apply this notion to the standardization of a set of simultaneous performances.

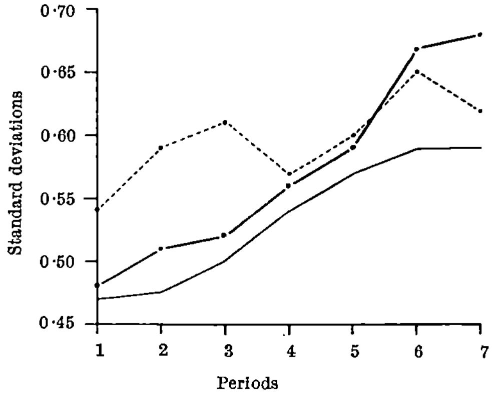

Fig. 2. Standard deviations for seven consecutive periods of sixteen days each for three trees during the season 1955–56 ———, Tree No. 1; ·—·—·, tree No. 2; ·--·--·, tree No. 3

Whatever the nature of the regulatory process, its efficiency can be measured. I suggest that the variance of a metrical character may be as important a property of an organism as its mean, and should be measured on a number of species. This is being done at this Institute, but I hope that similar work may be undertaken outside India. A detailed account of the work described here will be published elsewhere.

I wish to thank Prof. J. B. S. Haldane for help both with the practical and theoretical investigations.

BACTERIOLOGY

Reclassification of *Leuconostoc mesenteroides* P.60 as a *Pediococcus*

FOR some time it has been known that the organism widely used for the assay of amino-acids and called *Leuconostoc mesenteroides* *P*.60 is not in fact a *Leuconostoc*. McCleskey[1] examined *P*.60 and suggested that it might be *Streptococcus equinus*. However, the culture was atypical mainly because it produced ammonia and carbon dioxide from peptone. McCleskey suggested that the culture should be known as *Streptococcus* spp.

A strain of *P*.60 obtained from the National Collection of Industrial Bacteria, at Teddington, *NCIB* 8081, has been examined and found to have many features in common with *ATCC* 8081, and other strains of *Pediococcus cerevisiae*[2]. The comparison is given in Table 1.

Pediococci have only recently become recognized as a widely distributed genus, mainly because of the difficulty in separating them from other genera. However, *P*.60 possesses the essential characters of a *Pediococcus*. Morphologically it is a Gram-positive coccus occurring in pairs and tetrads, and can be separated from the morphologically similar aerobic Micrococcaceae by the type of growth produced on agar and because carbohydrate is required for growth. Unless catalase is demonstrated to be present in the *Pediococci*, the distinction between the *Streptococci*

Table 1. A COMPARISON OF *Pediococcus cerevisiae ATCC* 8081 AND *Pediococcus* (*Leuconostoc mesenteroides*) *P*.60

Similarities

Morphology	Gram + coccus in pairs and tetrads
Type of growth on yeast glucose agar	Small round unpigmented colonies similar to those produced by streptococci
Growth on nutrient agar	Very slight
Litmus milk	–
Hydrolysis of arginine	+
Growth at *p*H 9	–
Growth at *p*H 4·8	+
Acid produced from	Arabinose, fructose, glucose, galactose, mannose, cellobiose, trehalose, salicin, aesculin
No acid from	lactose, sucrose, dextrin, mannitol

Dissimilarities

		ATCC 8081	*P*.60
Catalase		+	–
Folinic acid		required	not required
Acid from :	xylose	–	+
	maltose	+	–
	glycerol	+	–

and the *Pediococci* rests on morphology. Gutekunst *et al.*[3] have shown that the production of catalase in the *Pediococci* may depend on the conditions of growth, and even when present may be difficult to demonstrate. *P*.60 has not been shown to produce catalase, and hence the confusion with the *Streptococci*. The lack of catalase does not exclude the culture from the genus *Pediococcus*.

Felton and Niven[4] examined several strains of *Pediococcus cerevisiae* and found that they all required folinic acid for growth, and they suggested that the need for folinic acid might be a "unique characteristic" required by the genus as a whole. Günther[5] has found that five out of thirteen strains belonging to *Pediococcus cerevisiae* do not require folinic acid.

It was intended to compare *P*.60 with authentic strains of *Streptococcus equinus* ; but attempts to obtain these cultures from world sources resulted in three cultures being received, each one different from the other. However, several other strains of *Pediococcus cerevisiae* have been examined, and it is now concluded that *P*.60 belongs to the same genus, and is not a *Streptococcus*. Günther[5] has confirmed the observations, and has placed *P*.60 with her group *I*, that is, *Pediococcus cerevisiae*.

Uronate Oxidation by Phytopathogenic Pseudomonads

THE pathway by which D-galacturonic and D-glucuronic acids are utilized by phytopathogenic *Pseudomonas* species is apparently quite different from the uronic isomerase–keturonic reductase system found in three genera of the Enterobacteriaceae[1–5]. In this new pathway of uronic acid catabolism, mucic acid has been isolated and identified as the initial product following the enzymatic oxidation of D-galacturonic acid; glucaric acid is presumably formed from D-glucuronic acid.

Cell-free extracts prepared from galacturonate- or glucuronate-grown *Pseudomonas syringae* and other phytopathogenic pseudomonads contain an enzyme which catalyses the rapid oxidation of either D-galacturonate or D-glucuronate with DPN+ but not TPN+. This enzyme, named uronic acid dehydrogenase, has been purified several-fold by ammonium sulphate precipitation, followed by *DEAE* cellulose column chromatography. Failure to find separate dehydrogenases, or to show differential activity upon either substrate during the several steps of purification, suggests that the same enzyme may catalyse the oxidation of both uronates. The purified enzyme does not act upon glucose, galactose, L-iduronate, or D-mannuronate, with either DPN+ or TPN+. Uronic dehydrogenase activity was found in extracts prepared from mucate- and glucarate-grown cells, but no detectable quantity of this enzyme was evident in extracts prepared from cells grown with glucose. Neither uronic isomerase nor keturonic reductase activity was detected in preparations from uronate-grown *P. syringae*.

The end-products formed upon the enzymatic oxidation of either D-galacturonate or D-glucuronate are non-reducing, lactonizing acids. Several mgm. of the oxidation product formed from D-galacturonate were prepared by coupling the *Pseudomonas* system with *Azotobacter*-reduced diphosphopyridine nucleotide-oxidase and oxygen. After deproteinizing and condensing the reaction mixture, a very insoluble white crystalline precipitate was obtained. Upon recrystallization from hot water, this substance had a melting point identical with that of authentic mucic acid ; no depression of melting point was observed when the two compounds were mixed.

The stoichiometric picture supports our belief that *P. syringae* converts galacturonate plus DPN+ to mucate plus reduced diphosphopyridine nucleotide ; 0·238 µmole of the latter appeared in a system originally containing 0·236 µmole galacturonate (Fig. 1). Furthermore, whole cells of galacturonate-grown, but not glucose-grown, *P. syringae* are sequentially induced to the oxidation of mucate.

Enzymatic attack on glucuronate similarly yields an equimolar quantity of reduced diphosphopyridine nucleotide (0·215 µmole from 0·214 µmole glucuronate ; Fig. 1). Glucuronate-grown, but not glucose-grown, whole cells are simultaneously adapted to the oxidation of glucaric acid. Unequivocal identification of the end-product, presumably glucaric acid, is at present under investigation, as are the steps beyond the sugar dicarboxylic acids in this new pathway of uronic acid metabolism.

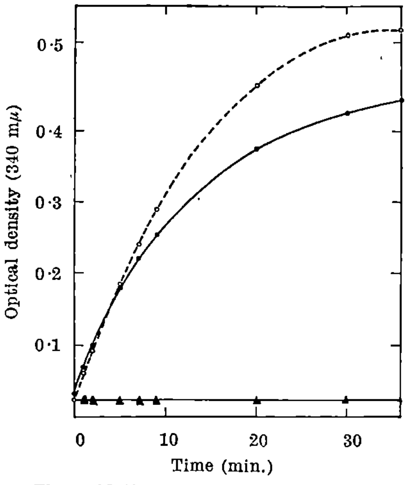

Fig. 1. The oxidation of D-galacturonate and D-glucuronate with DPN+ and purified uronic acid dehydrogenase from *Pseudomonas syringae*. Cuvette contents were : substrate (○—○, 0·236 µmole galacturonate ; ●—●, 0·214 µmole glucuronate ; ▲—▲, none) ; 100 µmoles *tris*-hydrogen chloride buffer, *p*H 7·4 ; 0·6 µmole DPN+ ; and 0·1 ml. enzyme ; final volume, 3·0 ml.

Oxidation of Thiosulphate by *Thiobacillus thioparus*

PREVIOUS investigations of the oxidation of thiosulphate by the autotrophic micro-organism *Thiobacillus thioparus* have not led to uniform results. According to Starkey[1], thiosulphate is oxidized directly to sulphur and sulphate, and Parker and Prisk[2] have also come to a similar conclusion. On the other hand, Vishniac claims that the oxidation of thiosulphate by *Th. thioparus* occurs in two stages: the first is the complete oxidation of the substrate to tetrathionate and the second the oxidation of the tetrathionate[3]. The results of Pratt's investigations[4] also suggest the possibility of the appearance of tetrathionate during the oxidation of thiosulphate by *Th. thioparus*. Pratt showed that in the medium in which *Th. thioparus* was growing there was an accumulation of some substance, presumably tetrathionate, giving a positive Folin–Ciocalteu reaction.

Our previous investigations, based on the application of thiosulphate labelled with radioactive sulphur[5], argue against the hypothesis which assumes tetrathionate to be an intermediate substance in the oxidation of thiosulphate by this micro-organism. The application of a very sensitive chromatographic method for the separation of inorganic sulphur compounds has now enabled us to collect some new facts contradicting Vishniac's hypothesis.

The strain of *Th. thioparus* which we have isolated corresponds in its biological and morphological characters to the micro-organism described by Natanson[6] and Starkey[1]. It was cultured in the medium previously described[7]. The centrifuged culture medium was subjected to chromatographic analysis, using Whatman No. 1 filter paper and solvent recommended by Stelmasźyńska[8] (acetone/*n*-butanol-I/water, 2 : 2 : 1). The chromatograms obtained were stained in darkness with 0·1 *N* silver nitrate and then washed in water, a solution of ammonia and water again.

In Fig. 1*a* is seen a chromatogram on which the distribution of thiosulphate and four polythionates is marked. Fig. 1*b* reproduces the chromatogram obtained from bacterial medium in which 50 per cent of the initial quantity of thiosulphate has been consumed. In this chromatogram only one spot corresponding to thiosulphate is visible. Similarly, the chromatograms of the medium taken after the consumption of 25 per cent of thiosulphate exhibited only a single spot corresponding to thiosulphate.

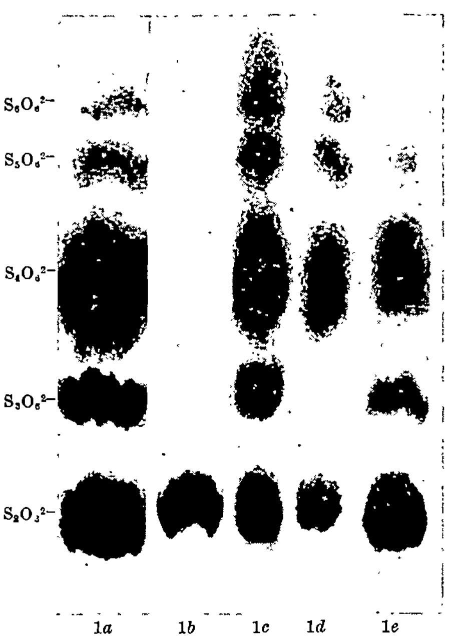

Fig. 1. Ascending chromatograms of thiosulphate and polythionate (*a*); of the reaction products between these substances (*c*, *d*, *e*); and of the medium in which *Th. thioparus* was cultured (*b*)

Our further experiments show that when tetrathionate appears in the solution besides thiosulphate, a series of spontaneous secondary reactions occur leading to the appearance of other polythionates. A mixture of equimolar (0·25 *M*) solutions of thiosulphate and tetrathionate, when subjected to chromatographic analysis, shows spots corresponding to trithionate, tetrathionate, pentathionate, hexathionate and probably heptathionate (Fig. 1*c*). If solutions of thiosulphate and tetrathionate are mixed with simultaneous addition of formaldehyde, there is an absence of trithionate in the products of the spontaneously proceeding reactions (Fig. 1*d*). We explain the appearance of polythionates under the conditions just described by the following reactions, the last of which is inhibited by formaldehyde:

$$^{-}S{-}SO_3^- + {}^{-}O_3S{-}S{-}S{-}SO_3^- \rightarrow {}^{-}O_3S{-}S{-}S{-}S{-}SO_3^- + SO_3^{=}$$

$$^{-}S{-}SO_3^- + {}^{-}O_3S{-}S{-}S{-}S{-}SO_3^- \rightarrow {}^{-}O_3S{-}S{-}S{-}S{-}S{-}SO_3^- + SO_3^{=}$$

$$SO_3^{=} + {}^{-}O_3S{-}S{-}S{-}SO_3^- \rightarrow {}^{-}O_3S{-}S{-}SO_3^- + {}^{-}S{-}SO_3^-$$

If, therefore, tetrathionate were to appear in the course of the oxidation of thiosulphate, we should expect to see, on the chromatograms of the medium, spots corresponding not only to this substrate but also to the other polythionates. As was previously stated, we have not seen this.

Of course, the objection may be raised that in the culture tetrathionate appears slowly, and that on account of this there occur conditions differing from those which arise after a rapid mixing of equimolar quantities of thiosulphate and tetrathionate. Wishing to decide this possibility, we carried out model experiments in which the tetrathionate solution was placed in a dialysing bag in a thiosulphate solution. The concentration of both solutions would finally correspond to that which would be found in the thiosulphate solution after the oxidation of 25 per cent of this substance to tetrathionate. Chromatographic analysis of the external and internal fluid taken after the experiment had lasted for 16 hr. at 32° C. showed distinct spots of thiosulphate, trithionate, tetrathionate and pentathionate (Fig. 1*e*). These results, in agreement with our former findings, lead to the conclusion that the oxidation of thiosulphate by *Th. thioparus* does not pass through the intermediate stage of tetrathionate.

SOIL SCIENCE

Release of Fixed Ammonium from Soil by Ball Milling

RECENT research has shown that some soils have the ability to fix appreciable quantities of ammonium in a form not readily exchangeable with 1 *N* potassium chloride or available to plants and micro-organisms. Fixation results from a replacement by ammonium for interlayer cations (calcium, magnesium, sodium, hydrogen) in the expanded lattice of clay minerals. Since many soils contain the types of clay minerals known to fix ammonium, it may be deduced that they will contain fixed ammonium through the reaction of minerals with ammonium produced naturally. This deduction is supported by recent reports[1-4] that some soils contain considerable amounts of naturally occurring fixed ammonium. However, these findings require confirmation, since the methods employed cannot be considered entirely satisfactory.

The difficulty involved in the determination of native fixed ammonium in soil is that of finding a method that will secure quantitative release of fixed ammonium from clay minerals without causing decomposition of nitrogenous soil organic matter to ammonium. In the work reported here, the value of a method based on ball milling was investigated, since it was considered possible that grinding of soil under certain conditions might destroy the crystal lattices of clay minerals and release fixed ammonium without causing serious decomposition of organic nitrogen compounds. Studies were conducted with a clay mineral (vermiculite) and several soils. The vermiculite, which was previously saturated with ammonium and contained 9·6 mgm. of fixed ammonium nitrogen per gram, was ball milled both wet and dry. Steel jars and balls were used, since grinding of clay minerals with other types of jars or balls led to contamination of the minerals by abraded material. For wet ball milling, a 0·2-gm. sample was ground with 150 ml. of 1 *N* potassium chloride solution and 10 gm. of boric acid. Boric acid was added because preliminary experiments showed that ball milling of vermiculite and other clay minerals was accompanied by a marked rise in *p*H, which led to the loss of ammonium by volatilization. The ammonium released by grinding was determined by steam distillation of *N* potassium chloride extracts of the ball-milled materials, using a *p*H 8·8 borate buffer. The ammonia in the distillate was determined titrametrically, or colorimetrically with Nessler's reagent.

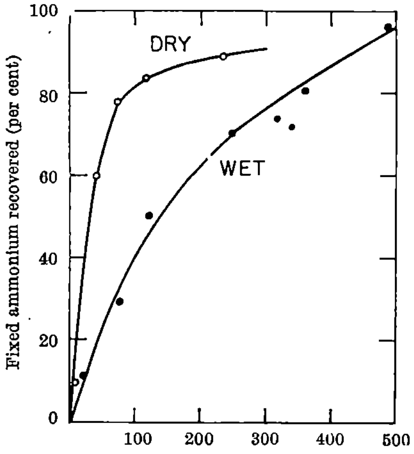

Fig. 1

The release of fixed ammonium in vermiculite to an exchangeable form as a function of time of ball milling is shown in Fig. 1. It can be seen that prolonged grinding was required to release the fixed ammonium and that quantitative recovery was not achieved. Dry ball milling was more effective than wet grinding, about 90 per cent of the fixed ammonium being released to an exchangeable form by dry ball milling for 230 hr. and by wet ball milling for 435 hr. Packing of unground material in the ends of the jar occurred in dry ball milling and this undoubtedly reduced the efficiency of grinding. Studies with a sample of vermiculite that had not been treated previously with ammonium showed that dry grinding for 290 hr. did not completely destroy its ammonium-fixing capacity, which indicates that either the crystal structure was not completely disrupted by grinding or that new types of ammonium-fixing minerals were formed.

The ball milling of several subsoils suspected of containing naturally occurring fixed ammonium led to a progressive increase in exchangeable ammonium with time of ball milling. For example, with a Cisne silt loam subsoil, 3·2 mgm. of nitrogen per 100 gm. was released by grinding for 48 hr., while 5·2 mgm. of nitrogen per 100 gm. was released by grinding for 120 hr. These results do not establish the presence of naturally occurring fixed ammonium in soil, since some of the ammonium released from the soil by ball milling could have come from the breakdown of soil organic matter. This possibility could not be tested directly, but experiments in which 1 gm. of clay-free peat soil was ball milled with 9 gm. of sand for periods up to 260 hr. showed that ammonia was produced in increasing amounts with increased periods of grinding. This finding must be interpreted with some caution, since the organic matter in peat soils may be more susceptible to decomposition by grinding than the material in mineral soils. Nevertheless, taken with the finding that quantitative release of fixed ammonium from vermiculite was not achieved even with long periods of grinding, this result indicates that methods based on ball milling are not likely to be of value for the determination of fixed ammonium in soil.

Simultaneous Decomposition Processes in Soils

It has been found[1] that following the moistening of a dry soil two independent decomposition processes occur, namely, (1) decomposition of soluble organic material without nitrification and (2) decomposition of non-soluble organic material with nitrification. Both rates of decomposition fall off rapidly, with (1) as the soluble substrate is exhausted and with (2) as physical changes, among others, occur at the surface. These changes appear to involve organic gels the surface area of which is increased by drying, possibly as a result of fragmentation or increased porosity. On first moistening, a greater surface area is exposed to solution processes (followed by (1)), and to decomposition (2) than later when, under continued moist conditions, reversible changes occur in the colloids leading to reduced surface area. Prolongation of the dry state, without the soil necessarily becoming drier, increases the magnitude of (1) and (2), which indicates that ageing, a typical colloidal phenomenon, is involved. Moreover, since the behaviour described under (1) and (2) is repetitive with successive dryings and rewettings the changes in the colloids must be reversible, indicating that elastic gels are involved.

Further evidence for this two-process decomposition has recently been obtained. When a dry soil was moistened with water, and with normal solutions of sodium, potassium, calcium and magnesium chlorides and put in the respirometer for seven days the following amounts of carbon and nitrogen were mineralized (Table 1, stage 1).

Duplicate samples which had been through the same procedure as the above were then air-dried for 9 days, remoistened with water and again put in the respirator for a week. The amounts of carbon and nitrogen mineralized during this second cycle are given in Table 1 (stage 2).

A separate experiment (unpublished) showed that the salts depressed the solubility of the organic material and this is reflected in the greater amount of carbon mineralized in the water-treated sample, particularly during stage 1, which followed a long period during which the soil was in an air-dry state. There is, however, no indication that a reduction in the amount of carbon mineralized has had a concomitant effect in reducing nitrogen mineralization. If, as mentioned earlier, the two decomposition processes are independent, there is no reason why the repression of one should affect the other. This experiment therefore confirms previous experiments[1] in which it was found that when the soluble soil-organic material was extracted and added to both sand and soil media it decomposed without nitrification. Moreover, when the solution and decomposition of this soluble material is repressed, as in the above experiment, one gets a truer idea of the carbon/nitrogen ratio of the material actually involved in nitrification processes which, as shown in Table 1, is considerably less than the generally reported value of about 10, which usually includes carbon mineralized from both nitrifying and non-nitrifying processes.

Table 1
(Mgm./100 gm. soil)

Treatment	Stage 1			Stage 2		
	Carbon	Nitrogen	C/N	Carbon	Nitrogen	C/N
Water	19·8	1·95	10·2	10·2	0·90	11·3
Sodium chloride	10·2	1·18	8·6	9·6	1·85	5·2
Potassium chloride	9·6	1·64	5·6	7·2	0·84	8·6
Calcium chloride	8·4	1·73	4·9	9·0	1·80	5·0
Magnesium chloride	12·0	1·69	7·1	7·8	1·67	4·7

Nitrification, on moistening a soil, occurs initially under favourable conditions because the surface area exposed to decomposition and nitrification processes is greater soon after moistening than later on. Further, the newly developing microbial population is more active. The decomposition of microbial remains killed by drying must also be involved. This combination of circumstances leads to the subsequent production of considerable quantities of mineral nitrogen sometimes equivalent to that in 1 ton of sulphate of ammonia for an acre-6 in. of soil. The amount produced depends on the humus content of the soil and the logarithm of the time the soil was in an air-dry state prior to moistening. The decline in the rate of nitrification after moistening has been found to conform closely to a first-order reaction. Both the effect of drying on nitrification and the course that this afterwards follows can therefore now be fairly well predicted. This is important in relation not only to soil fertility but also to the effect of nitrate on other soil constituents. It may, for example, affect the solution of bases.

In conclusion, it is interesting to speculate on the wider application of the principle involved in the drying effect (par. 1). It seems that further use can be made of a colloidal system which is reversible with successive wettings and dryings and which exposes the maximum area to solution and decomposition processes for only a short period after each wetting.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, May 19

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Prof. M. E. L. Mallowan: "Ancient Mesopotamian Concepts of the Animal World".* (Third of six lectures on "Animals in Archæology". Further lectures on May 26, June 2 and 9.)

Wednesday, May 20

University of London (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. R. S. F. Schilling: "Recent Studies of Chronic Respiratory Disease in Cotton Workers".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Discussion on "Simulation Studies of Industrial Operation". Opening Speakers: Mr. P. V. Youle, Dr. K. D. Tocher, Mr. W. N. Jessop and Mr. F. Musk.

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. Isabella Leitch and Mr. Angus Thomson: "Growth, Heredity and Nutrition".*

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "The Determination of Vitamin E; a Collaborative Study of Quantitative Paper Chromatography and the Development of a Recommended Method of Analysis".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. M. F. Perutz, F.R.S.: "The Molecular Basis of Life".

Thursday, May 21

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting. 5.15 p.m.—Dr. J. H. Watson: "Some Observations on Gold Refining and the Standard for Gold and Silver Coinage".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. G. A. Maclachlan, Prof. Helen K. Porter, F.R.S.: "Replacement of Oxidation by Light as Energy Source for Glucose Metabolism in Tobacco Leaf"; Mr. S. H. Revell: "The Accurate Estimation of Chromatid Breakage and Its Relevance to a New Interpretation of Chromatid Aberrations Induced by Ionizing Radiations".

Physical Society (at the Royal Institution, Albemarle Street, London, W.1), at 5.45 p.m.—Mr. J. A. Ratcliffe, F.R.S.: Presidential Address.

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. Ivan Polunin: "The Muruts of North Borneo and their Declining Population".

Thursday, May 21—Wednesday, May 27

International Transistor Exhibition (at Earls Court, London).*

Friday, May 22

Linnean Society of London (at East Malling Research Station, East Malling, Kent), at 11 a.m.—Meeting on "The Role of Plant Anatomy and Applied Botany".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with high academic qualifications together with research or industrial experience in some branch of physics) in Physics—The Principal, Lanchester College of Technology, Butts, Coventry (May 21).

Assistant Lecturer in Geography, and a Junior Research Fellow in Geography—The Registrar, The University, Sheffield (May 23).

Head (graduate of a British university) of the Department of Mathematics—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11 (May 29).

Lecturer or Assistant Lecturer (qualified in applied mathematics) in Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (May 29).

Dairy Officer (with a university degree in an agricultural science, preferably in dairying, or with postgraduate qualifications in dairying) in the Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (May 30).

Lecturer (Grade II), and an Assistant Lecturer (Grade III) in the Department of Zoology—The Registrar, The University, Bristol (May 30).

Research Assistant (graduate in chemistry or biochemistry), for work on urinary calculi in the Department of Veterinary Preventive Medicine at the Veterinary Field Station in Cheshire—The Registrar, The University, Liverpool (May 31).

Senior Lecturer or Lecturer in Physics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, May 31).

Assistant Editor (man or woman with a Ph.D. degree or equivalent research experience, and also some feeling for language, previous editorial experience not essential)—The General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1 (June 1).

Lecturer in Mathematics, and an Assistant Lecturer in Mathematics—The Registrar, University College of Wales, Aberystwyth (June 5).

Assistant Lecturer in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (June 12).

Lecturer on Physiological Psychology—The Secretary of Faculties, University Registry, Oxford (June 15).

Lecturer in Pure Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 20).

Senior Lecturer or Lecturer (with research or industrial experience with servo-mechanisms or in process control) in Control Engineering; a Lecturer (with a thorough knowledge of the physics of materials and preferably research or industrial experience involving solid state physics) in Materials; and a Lecturer (with good qualifications in light current electrical engineering or in physics) in Electronic Engineering—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (June 20).

Assistant Lecturer or Lecturer in Philosophy at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 25).

Chair of Geography in the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 30).

Senior Lecturer in Mathematics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 30).

Research Fellow (with M.Sc. or equivalent, with special knowledge and/or experience of agronomy of tropical crops) in Tropical Crop Production at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 1).

Senior Lecturer or Lecturer in Philosophy at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 4).

Lecturer (with an honours degree or higher degree in chemical engineering or equivalent qualifications) in Chemical Engineering at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Botanist (Plant Pathologist) (with a good honours degree in botany or agricultural botany and at least two years postgraduate experience in plant pathology) in the Department of Agriculture, Uganda, to diagnose the causes of crop diseases and recommend control measures, and to assist with the breeding of disease resistant crops—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/9/02.

Instructor or Assistant Professor in Protozoology—Dr. James R. Adams, Department of Zoology, University of British Columbia, Vancouver 8, Canada.

Lecturer and a Research Assistant (Academic) in the Physics Department, to take part in research in vacuum physics and photoelectronics applied to astronomy, nuclear physics, etc.—Prof. J. D. McGee, Physics Department, Royal College of Science, Imperial Institute Road, London, S.W.7.

Research Biologists (2) (with a science degree with honours in zoology), for research in introduced wild mammals in New Zealand, mainly species of deer—The New Zealand Forest Service, Wellington, New Zealand.

Research Engineers (2) (with at least an honours degree in mechanical engineering, or in some other specialization covering fluid mechanics, and preferably with some postgraduate experience) in the Department of Aircraft Propulsion, for theoretical and experimental work on the fluid mechanics of gas flow in solid rocket motors—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Senior Lecturer in Biology—The Registrar, College of S. Mark and S. John, Chelsea, London, S.W.10.

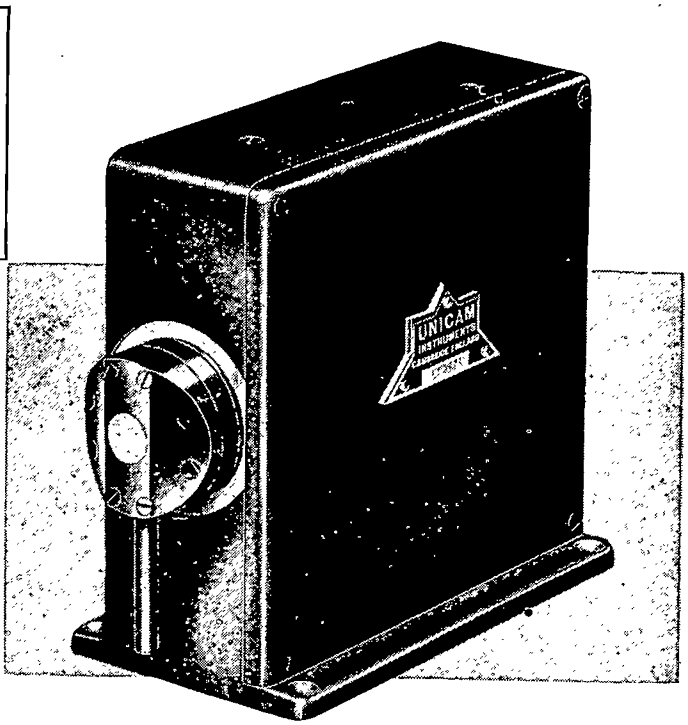
An
INFRARED DETECTOR



sensitive from Visible to Microwaves

The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows — KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ — 27 μ.
CsBr	,, ,, ,, 35 μ — 40 μ.
CsI	,, ,, ,, 45 μ — 50 μ.
Quartz (0.25 mm thick)	,, ,, ,, 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	,, ,, ,, 10 μ.
*KRS-5	,, ,, ,, 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

BRITISH BOOKS AND INFORMATION SERVICES OVERSEAS

WHEN speaking in the debate on defence in the House of Commons on February 25, Mr. A. Head, a former Minister of Defence, said that his visits to South-East Asia, the Middle East and Africa in the past two years had increasingly convinced him that Britain is losing the battle for men's minds. It is, of course, as a contribution to this ideological warfare that President Eisenhower on March 13 asked Congress for 3,930 million dollars to continue the U.S. foreign aid programme, which includes 179 million dollars for technical assistance programmes in 1960 and 30 million dollars as a contribution to the technical co-operation and special projects programmes of the United Nations. An appreciable proportion of Colonial Development and Welfare Funds may be regarded as directed to the same end, and the stress laid on education at the Commonwealth Trade and Economic Conference at Montreal, and on information services, particularly on broadcasting and television, in the last annual report on the Colonial Territories, further indicates the growing realization of the importance of seeing that an accurate and objective picture of Britain is presented to the world.

It is against this background that the proposals outlined in the White Paper on Overseas Information Services* are to be considered. The plans outlined in the earlier White Paper of July 1957 led to an increase in expenditure on overseas information services, from £13 million to £15 million a year, chiefly through an increase in the number and strength of information posts, the re-deployment of external resources of the British Broadcasting Corporation, increased resources for the Central Office of Information, more television films, and a substantial expansion of the work of the British Council. Despite this expansion, details of which are appended to the new White Paper, annual reports of the British Council continue to testify to the inadequacy of the present effort, and in the last annual report Sir Charles Snow refers in particular to the unsatisfactory position of British books and other printed matter in the world overseas, including the Colonial territories. This has been the subject of persistent Parliamentary questions, and the travels of Dr. Charles Hill, Chancellor of the Duchy of Lancaster, to whom the survey of British information services was entrusted, have apparently shown him that British books are facing heavy competition in various areas, and convinced him that action is required. Nevertheless, in reply to Lord Stonehaven's request in the House of Lords on February 18 for a statement of the Government's plans for facilitating the increased distribution and sale overseas of British books and periodicals, particularly in countries where there are sterling restrictions, the Earl of Home could only state that Dr. Hill's study of these problems is well advanced and that a statement will be made as soon as possible.

On this question of books, the White Paper admits that there are countries where import restrictions hamper the British publisher in selling books at normal prices, although in these and other countries there are large numbers of students and others who cannot afford to pay anything like the ordinary economic prices for British books which they need or wish to read, and that other countries have done more than we have to devise ways and means of overcoming such obstacles. But it merely comments that the Government is studying ways of encouraging the flow of British publications overseas. Apart from this, the supply of books in existing British Council libraries is to be increased and more resources made available for the presentation of books to universities and other libraries. In addition, financial provision is being made for a pilot scheme of lending books to university and technical students in some countries for the duration of a course or session without the requirement to return the borrowed books in a fortnight or month. At present, Sir Charles Snow puts the total cost of British expenditure on the dissemination of the printed word at less than £500,000.

In replying in an adjournment debate on March 26 on the supply of British books and films overseas, Dr. C. Hill amplified the information given in the White Paper. There are ninety-nine British Council libraries, and help is given in maintaining about forty others. In the current year, £60,000 was spent on new books for these libraries; next year this will be increased to £171,000, and expenditure on periodicals will also increase. As regards exports of books, in 1937 the total value of books sold was £10·5 million and 30 per cent were exported; for 1946 these figures were £27 million and 24 per cent; and for 1957, £60 million and 37 per cent; in terms of individual books, probably about half the production is exported. Dr. Hill pointed out that the two British book export schemes have been closed down for political reasons in the countries concerned; he gave no further indication of the Government's intentions, though he re-affirmed that the study of the problem is almost complete. He pointed out that it need not be Government money which is blocked, and that Government action is not the only way of dealing with the problem. He regards the teaching of English and the provision of books, directly or through libraries, as the most important part of our long-term information work, and hopes for a general discussion before long on British Overseas Information Services as a whole.

The Government announced in the House of Commons on November 3, 1958, that a more intensive effort is required to ensure that British ideas, policies and objectives are widely known and understood, and the proposals outlined in the white Paper will increase the expenditure on overseas information services by a further £1·5 million. The expansion is designed particularly to meet changing conditions and techniques in parts of Asia and Africa, particularly the demands arising out of the desire for education; although it should be pointed out that the White Paper gives scant attention to the possibilities of television, beyond observing that there is considerable scope for the establishment or development of television services in some Commonwealth and Colonial countries, and that much preliminary work is proceeding. Dr. Hill was questioned on this point in the House of Commons on March 16 and agreed as to the great and increasing demand which we are seeking to satisfy. The English language is in wide and growing use throughout the world as the language of education, administration, culture and technology, and it is this fact that gives such importance to the teaching of English, including the supply and placing of teachers, and the supply of the books and periodicals needed to sustain and increase its use. This is apart from the need to demonstrate continuously the merits of a free as compared with a totalitarian society, to show the British understanding of the aspirations of other nations and to counter hostile misrepresentations of our aims and achievements.

---

* Overseas Information Services. Pp. 8. (Cmnd. 685.) (London: H.M. Stationery Office, 1959.) 6*d*. net.

To do all this effectively requires, too, the maintenance of the reputation of British information services for accuracy and objectivity; but it should not be necessary to elaborate further the nature of these tasks to demonstrate how large a contribution this £16·5 million could make to the easing of the tasks of diplomacy and defence. As regards the British Council, the Government's proposals, which will increase the Council's grant to about £5 million, include the provision of more money to subsidize teaching posts, encourage exchanges of university teachers, offer more scholarships in Britain and provide special British Council officers to advise on problems in teaching English. The Council's work in Nigeria is to be strengthened, and provision made for exchange of visits and other activities in the educational and cultural fields with Czechoslovakia and Hungary.

On broadcasting, the growing listening public which local sound broadcasting stations command almost everywhere, and the increasing difficulty which short-wave transmissions from afar encounter in competing with medium-wave and very high-frequency programmes locally transmitted is emphasized, and the growing demand for recorded material on disk or tape for inclusion in local programmes is noted. To strengthen the signal of the Arabic, Somali and Swahili services, a new relay transmitter is to be completed at Berbera in the Somali Protectorate by the beginning of 1960, and the daily hours of transmission of the Arabic service of the B.B.C. are to be increased from 9·5 to 12 with increased coverage of events of local significance and greater local appeal in entertainment programmes. More help is to be offered to local broadcasting stations, particularly in eastern Africa and Aden, to which substantial grants have already been made from Colonial Development and Welfare Funds.

New posts are to be opened in the official information services and existing posts strengthened in New Zealand, South Africa and East Africa; but the main expansion of these official services will be in the production of material in the vernacular languages, as well as in English, for all Commonwealth countries, and in the improvement of communications. Special attention is being given to news items about people from overseas who are working or studying in the United Kingdom. More trade and technical periodicals will be distributed overseas, and the programme of visitors from overseas is again being expanded, especially for those from the Commonwealth.

The extent to which all this affects directly the work of the scientist and technologist is not very apparent from the White Paper itself, although it is obvious that measures to improve interchange, the flow of information—of the printed word and over the air—and to facilitate understanding and communication both within and without the Commonwealth must assist that increased scientific and technical co-operation for which the Duke of Edinburgh recently pleaded at Karachi. Moreover, the official services can never replace the work of the voluntary organizations, such as scientific societies. Some indication of the extent of present developments can, however, be gathered from the last annual report of the British Council, which during 1957–58 assisted more than 1,800 visits of scientific specialists to and from Britain—some 35 per cent of the total assisted. Indeed, of visitors to the United Kingdom in 1957–58 under the auspices of the British Council, 18·5 per cent were concerned with social studies, 42·6 per cent with science, 10·1 per cent with medicine, and 14·8 per cent with education, and the shift in subject pattern from the arts and humanities towards the pure and applied sciences is growing. British scientific books and periodicals form a considerable proportion of the Council's libraries, especially in those countries where interest in the sciences is high. While the scientist and technologist therefore will welcome the increased support to be given to overseas information services as indicated in the White Paper, the further statement of policy regarding measures to assist the flow of British books will be awaited with no less interest and even some anxiety. Until some measures have been taken to deal with the obstacles to the flow of British books abroad our economic and commercial interests, no less than those of science and technology, will continue to suffer, and British technology will not be effectively exported. Even such achievements as the nuclear reactor cannot be properly exploited if the relevant scientific and technical literature is not freely available. The full effect of at least some of the measures promised in this White Paper awaits action on the decisions to which it is to be hoped Dr. Hill's study will speedily lead him. Beyond this, however, the scientist or technologist who goes abroad should himself be among the best of Britain's interpreters, and possibly professional organizations and bodies responsible for young scientists and technologists going abroad for the first time could do more than at present to see that such recruits understand what is expected of them, the conditions they will meet and the equipment of mind and character as well as technique that they should take with them.

DEVELOPMENTS IN ADULT EDUCATION

Trends in English Adult Education

Edited by Prof. S. G. Raybould. Pp. xiii+258. (London: William Heinemann, Ltd., 1959.) 21*s.* net.

THE most remarkable feature of this book is that it should have been written at all. During the great debate of less than ten years ago some of the contributors to the book vociferously championed the pure white flag of liberal adult education and completely rejected all the mixtures which went under the false colours of extension classes, local education authority activities, informal pursuits, broadcasting and the like. Yet here is a book, more than half of which is concerned with trends quite unrelated to the traditional conception of adult education in Great Britain. It is a fine tribute both to the vigour of adult education itself and to the flexibility and resource of those who promote it.

With two exceptions, the contributors are all drawn from the department of adult education at the University of Leeds. They, and particularly the editor, deserve warm praise for setting down their recent experiences in such forthright, objective and yet provocative fashion; this applies no less to the two distinguished contributors from outside the University walls.

The great debate about the purpose and content of adult education was sparked off by Prof. S. G. Raybould himself in 1949. The issue, quite simply, was whether or not the time-hallowed name of adult education could be given to any activities unconnected with the tutorial classes which had been jointly developed by the Workers' Educational Association and university extra-mural departments. How the debate proceeded—and how other adult education activities developed apparently with the connivance of those who opposed them—is carefully set out in a well-written chapter by Roy Shaw. This, surely, should have been the starting point of the book.

The controversial place of the Workers' Educational Association in the adult education movement of to-day is carefully analysed by a great friend of the movement, J. F. C. Harrison. Regretfully he arrives at the only possible conclusion that the Association is but a shadow of its former self, has failed to adjust its aims and organization to the needs of 1959, and with bewilderment and frustration arising from lack of national leadership, stands in marked contrast to the buoyancy and optimism which marks the university adult education movement of to-day.

The latter is described by J. W. Saunders. Since 1945 the virtual monopoly of university services by the Workers' Educational Association has been challenged by education directly provided by the extra-mural departments of the universities, now recognized as 'responsible bodies' by the Ministry of Education. Besides traditional classes for the 'workers', extra-mural departments are providing an ever-increasing number of specially designed courses to appeal to specialized professional people and to students who have had the privilege of a secondary and even a university education; "new social purposes, new social fulfilments are being met". If, as Sir Charles Morris writes in the foreword to this book, "at all stages a great part of education must always be self-education", the university extension movement is surely right to give urgent attention to the quality and standard of people who emerge from schools and universities into a world of specialists.

Other chapters describe the increasing attention paid to adult education by local authorities; the direct contribution of broadcasting and, incidentally, the value of market research in giving the customer what he requires; the immeasurable value of residential adult education colleges by their most worthy exponent, Guy Hunter; the educational influences of organizations such as Women's Institutes, Townswomen's Guilds and various local societies; some experimental work in trade union education which needs to be followed up with much greater enthusiasm than appears to be the case; and finally, a review by Prof. Raybould of developments since the Ashby Report was published in 1954. Most of the recommendations set out in that Report have been implemented; their influence on adult education trends have been considerable. One recommendation made by the committee was that sooner or later adult education must fight for a due share of the finances of universities, instead of continuing to be a branch of university activity protected by ear-marked grants from the Ministry of Education. Prof. Raybould believes that the time to adopt this recommendation has arrived. His views are earnest and compelling and could well initiate another great debate.

T. H. HAWKINS

THE PSYCHOPATHOLOGY OF SCIENCE

The Sleepwalkers

A History of Man's Changing Vision of the Universe. By Arthur Koestler. Pp. 624. (London: Hutchinson and Co. (Publishers), Ltd., 1959.) 25*s.* net.

THE story of the substitution for the tight, cosy, Earth-centred world of Aristotle of the infinite, centreless, mechanistic universe of Newton is a drama which the dullest of historians could not conceal; it is told again by Mr. Koestler with all the stylistic verve of an experienced novelist and with adroit use of the materials and ideas pieced together by historians of science during the past two generations. Through detailed studies of Copernicus, Kepler and Galileo as examples of the medieval, the transitional and the 'terrifyingly modern' scientific mentality the author has succeeded brilliantly in giving the general reader a vivid account of what the change from medieval to modern cosmology involved. For this is the core of the book; nothing between Aristarchos and Copernicus holds much interest for Mr. Koestler, and his account of cosmology after Galileo is equally brief. Newton's austere mind commands his admiration, but not his imaginative sympathy.

Although he makes effective—not invariably quite accurate—use of recent work in the history of science, Mr. Koestler's opinions will not always commend themselves either to scholars or to scientists. He constantly under-rates Ptolemy's great achievement because he finds the theory of epicycles ridiculous, while recognizing that the epicycles were tools of mathematical analysis and not regarded as physical realities. Conversely, he argues that Galileo should have been satisfied with the status of the Copernican system as a "working hypothesis", since he could not prove its *de facto* truth. Yet the Church was only prepared to admit Copernicanism as a calculating device, precisely like Ptolemy's epicycles. To overlook this fact and to under-estimate Galileo's concern with physical reality rather than with mathematical hypotheses of planetary motion is to run in peril of the "double-think" that Mr. Koestler detects in others, and contributes to that lack of feeling for Galileo which is so marked and astonishing a feature of this book.

For Mr. Koestler is a violent partisan in the way he treats ideas and characters. For him Copernicus is a fumbler, a second-rate second-hand Aristarchos, cold, timid, anxious ; Galileo is arrogant, vain and deceitful, contemptuous of the achievements of others and rashly confident that he can over-reach the theologians, so precipitating a disastrous and unnecessary conflict. Kepler is the hero of the story because his scientific discoveries were the fruit of his mystical leanings ; Galileo its villain because he turned his back on Kepler and constituted himself the champion of science against religion. All this forms an interesting and provocative point of view ; but it is a highly personal one.

Not less singular is Mr. Koestler's chief term of historical appreciation : schizophrenia. The tension he finds in the history of cosmology he attributes to "split-mindedness" and its product "double-think". This journalistic distortion of a precise psychopathological concept may itself be deplorable to purists : it becomes objectionable to historians when the whole of the Middle Ages is dismissed as an age of the split mind, and to physicists when quantum mechanics enters the category of "double-think" (whatever that may mean). Perhaps one should not insist on an author's idiosyncrasy ; in this book, however, psychological theorizing is fundamental to the interpretation of history, and to the conclusions of the epilogue on the contemporary state of scientific thought. In short, the brilliance of the book lies in the literary use of recent historiography ; Mr. Koestler's allusions to the mental hospital give it an additional and perhaps more dubious colour.

A. R. HALL

THE PINNIPEDIA

Seals, Sea Lions and Walruses

A Review of the Pinnipedia. By Victor B. Scheffer. Pp. x+179+32 plates. (Stanford, Calif. : Stanford University Press ; London : Oxford University Press, 1958.) 30*s*. net.

THE Pinnipedia are a highly specialized group of about thirty species, which present unusual difficulties to the systematist. Their large, greasy skins are difficult to preserve, and are consequently scarce in museum collections ; the skeletal parts, especially skulls—on which the systematist has usually to rely for comparative material—in some cases undergo progressive change of form and proportion as the animal's age advances. Particularly in the various polygamous species the males do not stop growing at maturity, as do most warm-blooded vertebrates, but may continue to increase in size, in some species quite rapidly, throughout life. Consequently the average measurements of a sample can be materially affected by the age-composition of the group from which it was taken. In these circumstances the diagnosis of subspecies often proves almost impossible, and the boundaries between species and genera sometimes appear indefinite also. In the past, confusions of names have been common and synonyms are therefore unusually numerous.

No comprehensive synopsis of the Pinnipedia has appeared since the early years of the century, and this makes Dr. Scheffer's modern, practical and authoritative review of their taxonomy and distribution particularly welcome. I notice with interest that he feels the group ought to be regarded as an order in its own right, separate from the Carnivora. Fifteen of the twenty genera into which he divides the present-day forms are monotypic ; among these is *Phoca*, to which only the common or harbour seal (*P. vitulina*) is here assigned. Seals are characteristically distributed coastwise, often strung out in long chains rather than occupying broad regions, and this may have facilitated speciation. In none of the five polytypic genera is there any instance of two species in the same genus (as defined by Scheffer) occurring together in the same area.

Some of the more widespread species have disrupted ranges : the harbour seal, for example, has two distinct North Atlantic centres, one on each side, and two corresponding ones in the Pacific. Here the author has decided to assign separate subspecific names, notwithstanding the fact that constant physical differences between the races are not always discernible. The name *mellonae* is applied to a fifth, freshwater population in Ungava, "not because it stands for a remarkably different kind of seal but because it represents a situation . . . ". Such an unorthodox criterion is presumably justified by the convenience of having labels for populations which are geographically distinct and definable as living entities.

The systematic section is prefaced by fifty pages of highly condensed, almost laconic information, chiefly on the anatomy, physiology and evolution of seals. The introduction contains an illuminating table in which the world populations of all the numerous forms are critically estimated ; one recent race—the fur-seal of Juan Fernandez—is probably extinct, and some others are dangerously low ; but considering the ravages that seals and their allies have suffered all over the world at the hands of man they have shown surprising powers of resistance and recovery.

The book contains distribution maps, excellent photographs and figures, and a very full bibliography. Only systematic names are listed in the index ; but some indication of the numerous topics included in the book can be gleaned from the subheadings to the introductory chapters, given in the table of contents. It is a very useful work of reference.

V. C. WYNNE-EDWARDS

BRITISH WATER BEETLES OF THE FAMILY HYDROPHILIDAE

British Water Beetles

Vol. 3. By Prof. Frank Balfour-Browne. Pp. liii+210. (London : The Ray Society, 1958. Sold by Bernard Quaritch, Ltd., 11 Grafton Street, W.1.) 30*s*.

PROF. F. BALFOUR-BROWNE is much to be congratulated on having produced a third volume on British water beetles. The first two volumes, published in 1940 and in 1950, deal with the Hydradephaga, the present volume with the aquatic

Hydrophilidae. The author writes with intimate knowledge of the species dealt with, acquired during his long experience as a field naturalist. As in the previous volumes, no descriptions are given of the species, and a successful identification is dependent on the correct interpretation of the keys, aided, however, by many useful figures illustrating anatomical features. An account of the life-history of the Hydrophilidae is included in the introduction, and many interesting biological notes are scattered throughout the book. More information on the larvæ and their habitats—where these are known—would have been of much value, but it is hoped that this book will induce others to study the biology of these interesting beetles, as Prof. Balfour-Browne has done so ably in the case of *Hydrobius fuscipes*, L.

The maps showing county and vice-county boundaries are a great improvement on those given in the earlier volumes, and are most useful in showing at a glance the known distribution of a species. Few errors have been noticed in the text, but no map is given of *Ochthebius minimus* Fab. though quoted on p. 160, and many authors are mentioned without inclusion in the bibliography. An interesting account is given of the male genitalia in some species of *Ochthebius*, *Hydrœna* and *Hydrochus*. The author considers that the modifications described render the males of some species incapable of mating and he believes that in consequence parthenogenesis occurs. This is a problem requiring investigation.

Highly controversial are the author's views given under the heading "Distribution and Means of Transport", though what transport he envisages for flightless water beetles is not specified. His outlook on the problem of the present distribution of water beetles is dominated by his idea of recent "invasions" arriving not only at the coast from the Continent but accounting also for the occurrence of various local species, adapted to special habitats, in all parts of the country, such as *Helophorus tuberculatus* Gyll, in Lanark (p. 96). The occurrence of uncommon species in localities not previously or recently worked is no proof of their recent arrival, and especially is this true when the specimens collected are incapable of flight, as in the case cited (p. lii) of *Noterus crassicornis* Müll., a species which is common in a Fife loch where 90 specimens have been taken, all brachypterous. It is more likely that local aquatic species are the last remnants of a population that was formerly much more extensive, before drainage and cultivation had destroyed many habitats.

Argument is an excellent stimulus to further research, and Prof. Balfour-Browne has written a stimulating book which will arouse fresh interest in these beetles and prove of much value to the specialist.

Dorothy J. Jackson

THE ELUSIVE PARTICLE

The Neutrino

By Prof. James S. Allen. (Investigations in Physics, No. 5.) Pp. viii+168. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1958.) 36s. net.

This small book gives an excellent description of experimental work on the neutrino, which only in the past few years has been shown to have any direct physical property apart from balancing energy, momentum and spin in β-decays. It is a tribute to modern methods of experiment that neutrino-capture in hydrogen has been demonstrated by Reines and Cowan in spite of the fact that a neutrino beam could traverse a thickness of solid material measured in *light years* without appreciable loss. The timing of the book was unlucky, because it was written before or during the revolution which occurred in the last half of 1957 and in 1958, due to the discovery of the non-conservation of parity in β-decay. Dr. Allen was therefore obliged to cover the changes in "Notes added in Proof". This he has done satisfactorily, but the subject has been so much changed very recently that a much clearer picture would be possible now.

Nevertheless the book is a useful one since it is concerned mainly with descriptions of experimental methods in the very difficult field of neutrino physics, and does not go into details of theories, some of which have changed.

The subject has had a curious history. Experimentalists were misled for many years by the conservation of parity theory, which was not based on any universally valid evidence, into not looking for such an easily detectable phenomenon as the polarization of electrons in β-decay. Some wrong results in the electron-neutrino angular correlation experiments, understandable in view of their difficulty, also contributed to the confusion. However, now everything seems in order on the two-component neutrino theory of Lee and Yang, both for β-decay and for pion decay. It has not happened often that so tricky a field of physics has been cleared up so quickly, as a result of brilliant theoretical work, which suggested many key experiments.

LEGENDRE FUNCTIONS

Fonctions Sphériques de Legendre et Fonctions Sphéroidales

Tome 2. Par Dr. Louis Robin. (Collection Technique et Scientifique du C.N.E.T.) Pp. viii+384. (Paris: Gauthier-Villars, 1958.) 5,300 francs.

The second volume of Dr. Robin's comprehensive treatise deals with the associated Legendre functions $P^m{}_n(\mu)$, $Q^m{}_n(\mu)$. The problem of defining these functions for unrestricted complex values of m, n and μ was tackled by several mathematicians in the late nineteenth century, and finally solved by Hobson (1896), who used for this purpose the double-circuit contour integrals devised by Jordan and Pochhammer. An essentially complete theory was expounded in full in Hobson's classical treatise on spherical harmonics (1931), and Dr. Robin has based his book very largely on this work, with some extensions and some elaboration of detail. There are three sections. In the first, which occupies more than half the book, the formal discussion of the functions is developed in exhaustive fashion. In the second, asymptotic formulæ and the Stieltjes-Hobson inequalities are considered; in the third, convergence and summability of series of Legendre functions. The influence of Hobson and of other British mathematicians, for example, Barnes, Watson, MacRobert, is very evident, and little of importance has escaped the author's attention. The book is for reference rather than for light reading, and for British readers is scarcely likely to replace Hobson; but Dr. Robin has taken account of work done since 1931, and has also incorporated earlier work, for example, on

Cesàro summability (C, k) with $k<\frac{1}{2}$, which is only briefly referred to by Hobson.

In 1908, Barnes gave an alternative to Hobson's definition, using a contour of integration parallel to the imaginary axis and a gamma-function integrand. Dr. Robin refers to this and also to Barnes's penetrating study of asymptotic expansions. But since Barnes's work has never been published in full, and since he claimed that his methods diminish the labour to about one-third of that required on Hobson's approach, it would be interesting to see what, for example, the first section of Dr. Robin's book would look like if written out on Barnes's lines. This, however, would in no way detract from the value of the present volume as an admirable work of reference.

AVIAN FOLKLORE

The Folklore of Birds

An Enquiry into the Origin and Distribution of some Magico-Religious Traditions. By Edward A. Armstrong. (The New Naturalist: a Survey of British Natural History.) Pp. xvi+272+33 plates. (London: William Collins, Sons and Co., Ltd., 1958.) 30s. net.

Birds have always fascinated humanity. Only of recent years has proper attention been paid to the importance of folklore for the study of history and of the way people thought in the past. It is only just in time. Folktales and folklore were seldom written down but were passed from generation to generation by word of mouth. Nowadays the spread of so-called civilization has meant that, except here and there in outlying districts, everything has been forgotten. Recently there has been a move to collect what has survived and to examine at the same time the folk legends of modern primitive peoples. Fortunately, although not written down, pictures recalling the folklore have often been used as decorative motifs in peasant crafts, and a close study of these has helped to elucidate the underlying legends. Of course, not every figure of a bird either in prehistoric times or at a later period illustrates some myth or legend. Indeed, I doubt whether the bird-sign on the top of a staff which can be seen in the Under Cave at Lascaux in connexion with the happy looking rhinoceros walking away from the disembowelled bison nearby is anything but the sign manual of some hunter concerned with the painting of the scene. This may well have been made for some definite purpose, though not necessarily to illustrate what we should to-day call folklore. Whether one can talk about folklore as such in palæolithic times one may be allowed to doubt, but in the later periods there is often documentary evidence which explains some of the art.

Edward A. Armstrong is well known as a naturalist. He has written much on bird life, and his book, "The Wren", is deservedly popular. In the present volume he starts with early times and continues with chapters devoted to various species of birds which figure especially in folklore tales. Thus we find chapters on the goose, the red-throated diver, the raven, the green woodpecker, the eagle, the wren, and a number of song birds. Each chapter describes some of the legends attached to the particular bird or group of birds. There is also an account of the beliefs which have grown up in various places, that the dead return as birds; for example, the story of the fisherman seeking his dead brother who had foretold that he would return as a gannet after death and would be recognizable by his black armsleeves. The author has thrown out his net widely. In time he ranges from prehistoric to recent periods, and geographically from Hudson's Bay to Zimbabwe in Rhodesia. There are numerous and delightful illustrations, some line blocks, some in half-tone and one in colour. The book as a whole is a scholarly account of the subject and a great deal of material has been collected. It also makes good reading. Archæologically and anthropologically it is a work which the purchaser will find well worth possessing.

M. C. Burkitt

RESEARCH ON HORMONES

Recent Progress in Hormone Research, Vol. 14

Proceedings of the Laurentian Hormone Conference 1957. Edited by Gregory Pincus. Pp. vi+582. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 13.50 dollars.

The fourteen articles contained in this volume record the contributions and discussions at the 1957 meeting of the Laurentian Hormone Conference. Hormones are chemically diversified and include among their number proteins, polypeptides, steroids, and catechol amines. Their biological effects embrace practically all vital processes, while their applications to medicine include both psychiatry and general medicine. It is therefore inevitable that the good endocrinologist must keep in touch with many different sorts of research, and books like this one assist him to remain in contact with aspects of the subject which otherwise might be difficult to follow.

The first section of the book, devoted to a series of four papers on "Hormone Structure and Function," well illustrates how often small changes in chemical structure can profoundly alter biological activity. The actions considered in this section range from the inhibition or facilitation of the growth of tumours to the regulation of electrolyte metabolism. The next section, dealing with "Hormones in Growth and Development," contains three papers and is largely directed towards hormonal influences on protein and fat synthesis and catabolism. It includes a discussion of the effects of hormones in cattle production, and in mammary development and function. The third section is concerned with "Reproduction", and from this section can be seen how developmental abnormalities can profoundly influence the secretion of hormones and how in their turn the activity of hormones can play a part in sex development. The section on "Hormones and Metabolism" includes a discussion on the effect of hormones on lipoprotein and connective tissue metabolism. Finally, a section on "Neurohumors" includes a discussion of adrenaline, noradrenaline and their striking influence on many different processes.

The book includes discussions on subjects which embrace specialized organic chemistry, tumour growth, cattle raising, sex pathology, atherosclerosis, anxiety neuroses, and senescence. Hormones link the tesserae of this fascinating mosaic and it is perhaps not to be wondered at that the variety of subject and diversity of activity in the field of endocrinology continue to challenge many active minds.

F. G. Young

MICROSCOPY WITH X-RAYS*

By Dr. V. E. COSSLETT
Cavendish Laboratory, University of Cambridge

THE idea of making a microscope for X-rays goes back to the earliest days of the subject. In the original announcement of his discovery, Röntgen[1] describes an attempt to focus the new radiation and concludes from its lack of success: "das man mit Linsen die X-strahlen nicht konzentrieren kann, ist nach dem Mitgeteilten selbstverständlich". Although later experiments have shown that, in fact, a focusing effect exists, it is so small that an X-ray microscope on the lines of the usual optical microscope would be impracticably long. However, the advantages of using X-rays are so considerable that many attempts have been made to devise systems which do not include lenses. X-rays penetrate matter relatively easily, they offer the possibility of a higher definition of image than with light, and, more important, they are emitted (and absorbed) in a manner specific to the nature and amount of the elements present, so that analysis on the microscale becomes possible.

Reflexion Focusing

If X-rays are incident perpendicularly on a mirror, they pass straight into it and the amount reflected is negligible; but if the beam just grazes the surface, reflexion is almost 100 per cent efficient. Since all materials have a refractive index slightly less than unity for X-rays, total reflexion occurs for a beam passing from air into any physically denser material such as glass or metal. Hence it is possible to focus X-rays with a curved mirror, so long as they fall on it at glancing incidence. The 'critical angle' is very close to 90°, and so the glancing angle has to be less than 1°, at the wave-lengths so far employed. In consequence, scarcely any focusing takes place at right angles to the plane of incidence, so that the image formed by a concave mirror of spherical curvature is drawn out into a line: the focusing is highly astigmatic. As pointed out by Kirkpatrick and Baez[2], however, a second mirror in a plane at right angles to that of the first will produce a stigmatic image. Focusing systems of this type have been developed by Kirkpatrick and his school at Stanford University[3]. The alignment of the mirrors and the position of the object are somewhat critical at such small angles of incidence, and micrometer adjustments are required. Single-stage microscopes only have so far been built, since a compound microscope would involve undue loss of intensity in the succession of reflexions as well as great difficulty in alignment. The best results, obtained with test grids, approach the performance of a good optical microscope. McGee[4] claims a resolving power of about 0·5 micron, using mirrors of radius 8·5 metres and focal length 6·4 cm. To keep the exposure time within reasonable bounds (10–30 min.), he worked with a direct magnification of seven times only.

The obstacles to further development of the reflexion system are of two types: aberrations of the image, and practical difficulties in making the mirror surfaces. Lack of image brightness, giving long exposures, is also a limitation, since the aperture cannot exceed the grazing angle of total reflexion, that is, about 1°. The aberrations of the focusing system can in principle be overcome by using combinations of several mirrors with surfaces of special form — elliptical, paraboloidal, hyperboloidal — as shown by Wolter[5] and Pattee[6]. The correction obtainable with a pair of crossed ellipsoids followed by a pair of crossed paraboloids should give a resolving power of 500 A.—about twice as good as the ultra-violet microscope and four times better than the limit of the optical microscope.

The preparation of such corrected systems demands great skill and patience in polishing the surface to the required degree of perfection—about ten times better than that called for in the best optical practice. Not only must the surface be true to the particular aspherical form computed, it should also be smooth to almost molecular dimensions. For these reasons, it is difficult to estimate the ultimate performance to be expected from the reflexion X-ray microscope. It seems probable that the same definition as in the best optical microscope will be reached, but less likely that the limit predicted by Pattee is within practical possibility.

Contact Microradiography

The simplest way of obtaining enlarged images is by geometrical projection, dispensing with any form of focusing system, as in the usual method of medical radiography. Specimens partially transparent to the radiation, as most will be, form half-tone images rather than simple silhouettes. The limiting factor to the definition obtainable is set by the penumbra, formed at the edge of the true shadow. The definition can be increased, if microscopical detail is sought, either by reducing the size of the source or by moving the specimen close to the viewing screen (or photographic plate). The former, or projection method, allows high direct magnification, by bringing the specimen close to the source. The latter method yields no initial magnification, all the enlargement being obtained by subsequent viewing of the negative through an optical microscope; it has come to be known as 'contact microradiography'. So long as the X-ray source is far enough away for the penumbra to be of negligible width, the definition in the final image is determined by the size of grain in the developed emulsion and by the resolving power of the optical microscope used to enlarge it. With modern fine-grained emulsions, as prepared for spectrographic purposes, these two factors are of about equal order, namely, about 0·2–0·5 micron, so that the best contact microradiographs have almost as good a definition as the best optical micrographs.

The technique was developed, largely in France, between the two World Wars. Since 1946 it has been brought to a high art by Engström and his co-workers in Stockholm, especially for cytological studies. The first recorded application was to the study of the internal structure of alloys, however. Heycock and

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on February 6.

Neville[7], at the laboratory of Sidney Sussex College, Cambridge, in 1898 investigated the differences in size and shape of the precipitates formed when an aluminium–gold alloy was cooled quickly and slowly. Since that time the method has been gradually introduced into metallurgical practice, as in the work of Sharpe[8] and Andrews and Johnson[9] in Great Britain, and Trillat[10] in France. The applications in biology have been much more widespread, and have been recently reviewed by Engström[11]. By using very soft X-rays, it is possible to show clearly even cell components so small as a chromosome, without staining or otherwise interfering with them.

The great advantage of the contact method lies in its simplicity, and in the large field of view recorded. No special X-ray tube is required, though the exposure time can be cut appreciably (to 20 min. or so) by using one properly designed for the purpose[12,13]. The fine-grained emulsions demand careful handling, in dust-free conditions, on account of the high subsequent magnification that is needed. For highest definition, the specimen must be prepared as a thin section and brought into close contact with the emulsion, and Engström has developed special techniques for this purpose. In definition the ultimate limit is set by the resolving power of the optical microscope, so that a resolving power better than about 0·2 micron is not to be expected. The best contact micrographs from Engström's laboratory already approach this limit.

Projection Microradiography

In the projection method the specimen is placed close to the source, instead of close to the photographic plate, and a point source becomes the essential requirement in place of an ultra-fine grained emulsion. A point source is most simply obtained by placing a small aperture before an X-ray source of normal size, and the first 'pinhole-camera' radiographs were made in this way by Czermak in 1896[14]. The intensity of the beam through such an aperture was very small, however, and even with the improved tubes that later became available, it was impossible to combine appreciable magnification with reasonable exposure time (Sievert[15]). In 1939 it was pointed out by von Ardenne[16] that a point X-ray source of great brilliance could be formed by using magnetic lenses to focus the electron beam on to the target of an X-ray tube, the definition in the projection image being then limited primarily by the size of the source.

A point-projection system of this type was later constructed by Cosslett and Nixon[17] at the Cavendish Laboratory. To obtain a high demagnification of the electron source (a tungsten filament), two electron lenses are employed. The electron spot at the target can then be made smaller than 1 micron without difficulty, and even as small as 0·1 micron. The X-rays issue from this focal spot through the very thin target, which serves as window to the tube. An object placed close to it will form an enlarged image on a screen or plate at a distance. Since the source–object distance may be as small as 0·1 mm., a direct X-ray magnification of 100 × is obtainable in a camera-length of 1 cm., or of 1,000 × in 10 cm. The voltage on the tube has usually been in the range 5–20 kV., and the electron beam current is of the order of 1 μamp., concentrated into a focal spot of 1 micron or less. The dissipation of heat from such a small electron spot is so favourable that no water cooling of the target is needed.

The range of applications of the projection method is somewhat wider than that of the contact method, which is restricted by the need to have the specimen close to the recording emulsion. For example, it is better suited to the study of living subjects. Saunders[18] has followed up the earlier contact work of Barclay[19] and Bellman[20] in the field of microarteriography, and has studied the circulation in the ear of the rabbit under the influence of various treatments. The thickness of specimen that can be tolerated is greater than in the contact method, and may be as much as 1 mm. Smith[21], for example, has investigated the musculature of a series of beetles in the projection X-ray microscope. The whole of the internal structure is visible at once, whereas by optical techniques it would have to be worked out from a set of consecutive sections through the insect, owing to the limited depth of focus of the light microscope. A large number of other applications in mineralogy and metallurgy, in entomology and in botany, have also been explored.

In the projection system the depth of focus, in effect, extends all the way from the near side of the object to the photographic plate. It is thus possible to make stereophotographs of specimens much thicker than could be tolerated in the optical microscope; in the latter the focal depth decreases as the useful magnification increases, so that stereophotography at high power is impracticable. Excellent X-ray stereomicrographs have been obtained of alloy structures and of insects. Although it is possible to make stereophotographs by the contact method, it is more trouble both to make the initial pictures and to identify the same area in the two negatives.

The projection method is to be preferred for microradiography whenever the area of interest can be readily identified, by optical or other means, and mounted in the X-ray beam for the production of a direct image. On the other hand, the contact method provides a much larger initial field of view, from which areas can later be selected by exploration of the micronegative under the optical microscope. The exposure-time of the projection method is shorter by a large factor, being of the order of 1 min. The resolving power is limited, not by that of the optical microscope, but by the size of the electron spot on the target and the extent to which electrons are scattered in it before producing X-rays. The best results so far obtained by Nixon[22] and by Ong and Le Poole[23] are in the region of 0·1 micron, the limit of resolution of the ultra-violet microscope. The projection method thus already gives a higher resolving power than either the reflexion or contact methods. Further progress is at present hindered by lack of intensity, since the current that can be focused into the focal spot falls rapidly as its diameter is made smaller, but there is good reason for supposing that the resolving power will be improved to 0·05 micron (500 A.) and fair hope that it will reach 250 A.

Microanalysis by Differential Absorption

Both the contact and the projection methods of microradiography may be used to determine the nature and proportion of the chemical elements in a specimen, by making use of the steps which occur in the absorption spectra. The absorption coefficient of a given element changes abruptly at a well-defined wave-length, whereas that of the matrix in general increases smoothly and approximately in proportion to the cube of the wave-length. The steps are relatively infrequent, so that it is rare for the wave-lengths for two elements to be too close to be separable with an X-ray spectrometer. If measurements of X-ray transmission are made at wave-lengths just below and just above that of a step, then the difference will be due to the presence of the corresponding element, after allowing for the small change in absorption by the matrix. Knowing the height of the absorption step for the pure element, the observed height gives at once the percentage of it present in the matrix. By this means practically all elements in the Periodic Table may be determined quantitatively.

In the contact technique it is necessary to take micrographs of the specimen at two selected wave-lengths for each of the elements to be estimated. The difference in absorption in particular regions is found by measuring the relative transparency of the negative with a microphotometer. For accurate work, the photographic processing has to be carefully standardized, and it is preferable to make measurements on the original negatives rather than on enlargements. The smallest area that can be analysed is then limited to that of the smallest light spot which can be formed in the microphotometer—about 5 sq. microns. Lindström[24] has carried out micro-analyses of sulphur, phosphorus and calcium in sections of certain biological tissues, with an ultimate sensitivity of between 10^{-11} and 10^{-12} gm. and a relative accuracy of ± 3 per cent. On the other hand, if only the amount of matter present per unit area is of interest, as in many cytological investigations, an absorption measurement at a single wave-length is sufficient, provided that the composition of the absorber is known within certain limits. By this means Engström[11] has been able to make determinations of the dry weight of cell constituents with an accuracy almost as good as that achieved by the interference microscope.

Absorption microanalysis is more easily carried out by the projection method, since it is then unnecessary to make a photographic negative: the relative transmission of different points in the specimen is measured directly by placing an aperture, behind which is a spectrometer and counter, at the required points in the projected image. Röckert[25], in conjunction with Long[26], measured the micro-distribution of calcium in the cementum layer of the teeth of monkeys of different ages, and taken from different positions in the jaw. It turned out that there was no significant trend: the variation for a tooth of given type, in different individuals, was much greater than the variation in the average value with age or position. Long has used the same technique for determining calcium in a number of minerals, and Mosley and Wyckoff[27] have made qualitative surveys of other elements.

Emission Microanalysis

An alternative method of elementary analysis is by spectrometry of the characteristic emission lines excited when the specimen is made the target in an X-ray tube. From the position of the lines the elements present may be identified and intensity measurements give their relative concentration. By comparison with pure standard samples, the absolute amount of each element can be calculated.

The method has been practised on large-scale specimens for a long time, both by direct excitation on the target of a tube and by fluorescent excitation, in an intense primary X-ray beam. Its application on the micro-scale was first made by Castaing and Guinier[28]. They employed electron lenses to form a point focus of electrons on the specimen, placed inside the tube, and analysed the X-rays excited at a particular point in its surface, selected by means of an optical microscope built into the electron lens. Improvements now allow all elements in the Periodic Table, from uranium down to aluminium, to be analysed to an accuracy of 0·1 per cent in areas of diameter about 1 micron. Such a static spot X-ray microanalyser is now in production in France.

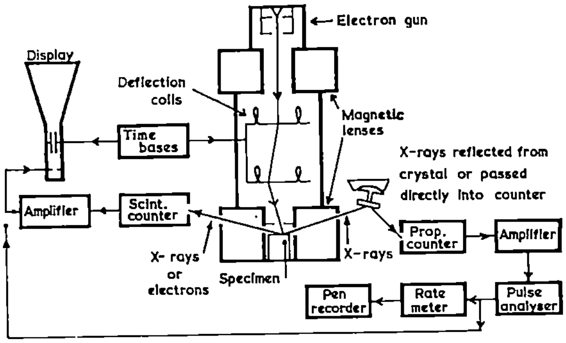

Fig. 1. Schematic diagram of X-ray scanning microanalyser

It would be helpful to be able to see exactly what point in the surface of the specimen was being struck by the electron spot. The flying-spot technique, already applied in optical and electron microscopy, was therefore combined with the microanalyser[29], as shown schematically in Fig. 1. The X-ray output is detected with a counter, amplified and used to modulate the beam of a cathode-ray tube operating in synchronism with the scan of the electron beam across the target. If the undifferentiated output is so displayed, an image is obtained of the specimen surface in terms of its total emissivity of X-rays. If a particular emission line is selected, the image shows the distribution of the corresponding element over the specimen, the local brightness depending on the amount of the element present at that particular point. By 'tuning-in' to each element present, a semi-quantitative analysis of the area scanned can be quickly carried out. When the elements are not near neighbours in the Periodic Table, the necessary selection of the emission lines can be made with a proportional counter alone, but with next neighbours it is at present essential to use a Bragg spectrometer. The collected intensity is then lower and a slow scan has to be used, the image being formed on a screen of appreciable 'memory' (long-delay tube), in order to gain a storage effect.

If a more accurate analysis is required, the electron spot can be made to scan along a given line and the output fed to a pen recorder, which traces out the variation in amount of the selected element across that part of the surface. Alternatively, the scan may be stopped and the electron spot moved by manual control to a point of special interest. The relative intensities of the X-ray lines of the various elements present are then recorded on a chart as the spectrometer selects them from the emitted spectrum (Fig. 2). After correction for differential absorption in the target and recording system, an accuracy of 0·05 per cent can be obtained in favourable cases, but the accuracy falls with the amount of element

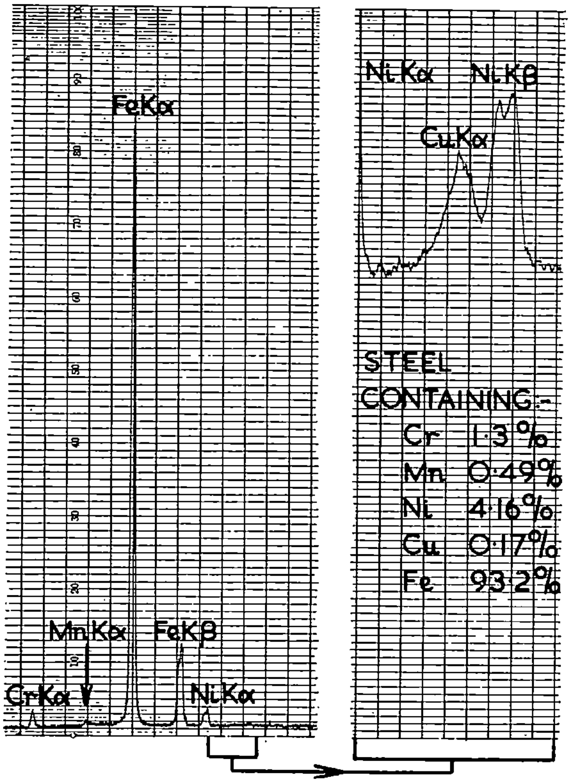

Fig. 2. Analysis of steel with the X-ray microanalyser

present. The electron spot can be made as small as 1 micron in diameter without undue loss in signal strength, so long as a high proportion of an element is present. At the voltages used on the tube (15–25 kV.), the electron beam penetrates a few microns into most metals before its energy falls too low for excitation of their characteristic X-ray lines. A volume of a cubic micron or so can thus be analysed, containing a mass of about 10^{-11} gm., and the sensitivity, the smallest amount that can be detected, is between 10^{-14} and 10^{-15} gm. Although some methods of analysis can give greater accuracy of determination, and one or two methods can equal the sensitivity, none can provide anything like the same degree of microscopic localization as in the X-ray microanalyser. For this reason it is finding increasing application in metallurgical[30], mineralogical[26,31,32] and, to a lesser extent, biological research.

The original scanning microanalyser was made by adapting an old electron microscope. An improved model has now been constructed at the Tube Investments Research Laboratories, Hinxton, which will be used for metallurgical investigations. It allows three spectrometers to be trained on the specimen, so that three elements can be analysed simultaneously. The scanning system has now also been incorporated in the Castaing-type microanalyser constructed at the A.E.I. Research Laboratory, Aldermaston, and shown at this year's Physical Society Exhibition. A simpler instrument has recently been built by Long[26], designed primarily for mineralogical work. Since most rock sections are thin enough to be optically transparent, a microscope is built into the side of the vacuum chamber, so that the section may be searched to select areas of interest for scanning; a fluorescent glow usually appears where the electron spot strikes it. As before, an image is displayed on a long-persistence cathode-ray tube screen, showing the surface distribution of a particular element in the rock, or the variation in concentration along a line may be shown. By using a double-beam display tube, the concentration can be graphed immediately above the trace of the path along which the analysis is made. For high accuracy, a pen recorder may be coupled up in place of the double-beam oscilloscope; but where an analysis to no better than 1 per cent suffices, it may be obtained directly from the photograph of the latter. A number of microanalyses of minerals and meteorites has been made[26,31,32].

The further development of the emission microanalyser faces the difficulty that the X-ray intensity decreases as the size of spot is reduced. Duncumb has analysed precipitates as small as 0·25 micron, with a spot rather larger, but the signal was very weak. Analyses of still smaller regions can certainly be made with the instrument as it is; but the time required becomes prohibitive for routine operation, and the output is insufficient for visual observation. Intensity might be increased in three ways: by improved design of the electron gun; by correction of the spherical aberration of the electron lenses; and by collecting a greater proportion of the emitted X-rays. Research on all three lines is in progress in the Cavendish Laboratory and elsewhere. There is reasonable prospect of substantial improvements, especially in the third direction, and we may expect to be able to analyse particles as small as 0·1 micron in the near future.

The other main problem is the extension of the range of elements that can be analysed, from aluminium down to nitrogen and carbon. The detection and separate estimation of these elements is of great importance for ferrous metallurgy, where carbides and nitrides abound. If this can be done—and the prospects are encouraging[33,34]—then the scope of the X-ray microanalyser will be greatly increased, and it might also become of value to the biologist. At the moment, it is possible to detect and estimate the concentration only of heavier elements that may be present in pathological conditions, such as tin or silica in the lung. Even when carbon, nitrogen and oxygen can be analysed, however, it remains doubtful if it could be done without charring the tissue or otherwise removing constituents selectively by the electron bombardment. The usefulness of emission microanalysis for the biologist must therefore remain an open question until more experience has been gained. In metallurgy and mineralogy its value is already established, and it is now a question of exploring its limits. The peculiar combination of microscopic imaging with microanalysis appears to be more powerful, within its range of resolution, than any other optical or electron optical methods yet devised, so that the new technique, whether or not one admits its classification as a microscope, is rapidly finding a place of its own among research tools.

HETEROGENEITY IN DEOXYRIBONUCLEIC ACIDS

I. Dependence on Composition of the Configurational Stability of Deoxyribonucleic Acids

By Dr. JULIUS MARMUR and Prof. PAUL DOTY

Department of Chemistry, Harvard University, Cambridge, Mass.

THE base-pair interactions that unite the two chains of deoxyribonucleic acid in its native, helical configuration are of two kinds: adenine–thymine and guanine–cytosine[1]. Because these pairs involve different numbers of hydrogen bonds[2] and are otherwise dissimilar, it is to be expected that they contribute differently to the stability of the helix. We wish to report here the magnitude of this effect (which is substantial), its use in estimating the extent of heterogeneity in composition within samples of deoxyribonucleic acid and to some degree within its molecules, and its importance in inactivation studies.

Upon heating neutral solutions of deoxyribonucleic acid, striking changes in some properties[3] (for example, viscosity, extinction coefficient, light scattering and optical rotation) are known to occur in a relatively narrow range of temperature. These changes reflect a transition from the double-stranded helical configuration to a disordered coil: the transition is essentially the melting of one-dimensional crystallites and may be characterized by the temperature at the midpoint of the transition, T_m. In earlier studies[4] on calf thymus deoxyribonucleic acid there appeared some indications that the transition consisted of a series of overlapping transitions of individual deoxyribonucleic acid molecules having different melting temperatures.

In particular, the transition was broader than expected for such very long, perfectly formed helices, and at temperatures within the transition region the viscosity would quickly reach a constant value and fall further only if the temperature was increased[5]. Furthermore, electron microscopy revealed that within the transition region only two types of deoxyribonucleic acid molecules could be discerned, namely, completely denatured or native ones[6]. The most reasonable explanation lay in assuming that the two hydrogen-

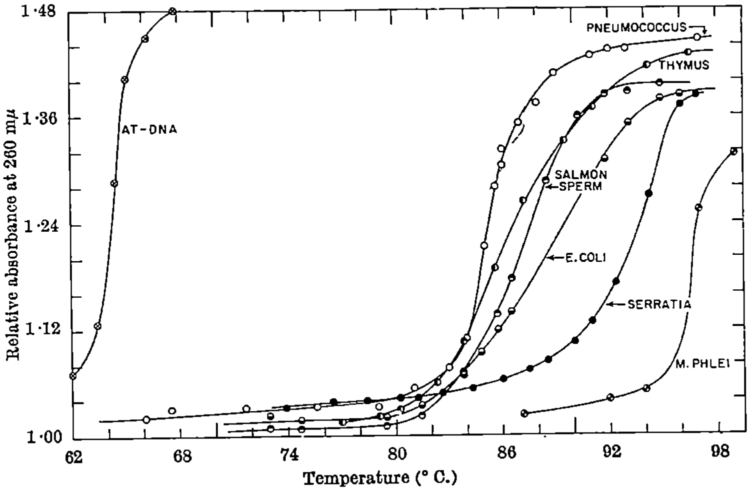

Fig. 1. Variation in absorbance (260 mμ) as a function of the temperature of the deoxyribonucleic acid solution. The result for bacteriophage T_4r deoxyribonucleic acid is not plotted because of serious overlap with *D. pneumoniae*. It was sharper and had T_m equal to 84°. In all cases the solvent was 0·15 *M* sodium chloride plus 0·015 *M* sodium citrate. The samples of bacterial deoxyribonucleic acid were deproteinized by successive mild shakings with chloroform and *iso*amyl alcohol. The samples of animal deoxyribonucleic acid were prepared by the Simmons technique using detergents (see ref. 5). The bacteriophage T_4r deoxyribonucleic acid was a gift from Mr. J. Fleichman

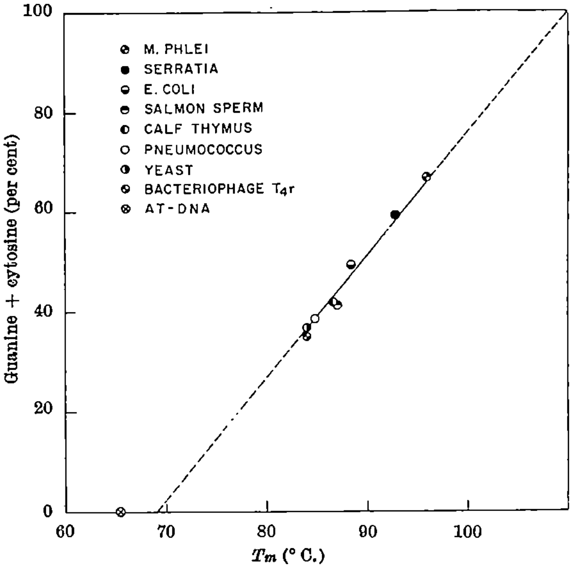

Fig. 2. Dependence of the denaturation temperature, T_m, on the guanine–cytosine content of various samples of deoxyribonucleic acid

bonded base pairs (guanine–cytosine and adenine–thymine) contributed unequally to the stability of the helix, thereby causing T_m to depend on the mean composition of either whole deoxyribonucleic acid molecules or large segments thereof.

In order to test this proposal, we have prepared a number of protein-free samples of deoxyribonucleic acid of different base composition from various sources (see Fig. 1) and determined their transition profiles by measuring the absorbance at 260 mμ as a function of the temperature of the solution. These are recorded in Fig. 1, and the melting temperatures are plotted as a function of the guanine–cytosine content[7] in Fig. 2. In the solvent used (0·15 *M* sodium chloride and 0·015 *M* sodium citrate), it is seen that T_m ranges from 85° C. for deoxyribonucleic acid from *Diplococcus pneumoniae* to 97° C. for that from *Mycobacterium phlei* in a manner directly proportional to the guanine–cytosine content. The T_m values are reproducible to within 0·5 deg. for different carefully prepared samples, and hence they may be considered as intrinsic characteristics of total deoxyribonucleic acid from a given species.

The extrapolation of the results in Fig. 2 permits an estimation of the T_m of deoxyribonucleic acid made exclusively of one base-pair or the other; for adenine–thymine this is 69° C. and for guanine–cytosine it is 110° C. The gift of a sample of adenine–thymine deoxyribonucleic acid[8] allowed us to check one of these predictions. The melting profile is shown at the extreme left of Fig. 1; its T_m value is 65° C. (In contrast to samples of naturally occurring deoxyribonucleic acid, the absorbance–temperature curves of which are far from being reversible, this adenine–thymine deoxyribonucleic acid exhibited complete reversibility. This behaviour would only be possible if the adenine–thymine sequence was strictly periodic.) In addition to verifying the dependence of T_m on composition, the magnitude of the hyperchromicity observed for this sample (52 per cent) supported the trend seen in the naturally occurring deoxyribonucleic acid samples between the hyperchromicity and the composition. In these the hyperchromicity decreased from about 44 to 34 per cent as the guanine–cytosine content increased from 38 to 67 per cent. Thus, in the limit of pure guanine–cytosine deoxyribonucleic acid, the hyperchromicity would probably be only about 25 per cent. Of course, this can only be a rough correlation, because the hyperchromicity in a given sample probably depends on sequence as well as overall composition.

An estimate of the dispersion of the guanine–cytosine content among the molecules of a given sample can be made in the following way. The melting profile of the adenine–thymine deoxyribonucleic acid, since it is of high molecular weight ($S_{20,w}$ = 12·6 *S*.) and with no heterogeneity due to composition, can be assumed to represent the natural transition width due to the intrinsic nature of this co-operative phenomenon. The displacements of this curve from its T_m can then be subtracted from the other melting profiles to give corrected profiles that should reflect only the spread due to heterogeneity of composition. This has been done for the samples studied with the following results. The transition of T_4r bacteriophage deoxyribonucleic acid had the same sharpness as the adenine–thymine deoxyribonucleic acid; hence the deoxyribonucleic acid molecules in this case appear to have essentially identical composition. The profiles for *D. pneumoniae* and *M. phlei* were only slightly broader. The remaining samples of bacterial deoxyribonucleic acid showed increased broadening of the transition, indicating significant heterogeneity in composition. The broadest profile is that from calf thymus; the central part of this transition (50 per cent of the rise in absorbance) covers about 4°. Since the slope of the line in Fig. 2 equates a change of 1 deg. in T_m to a 2·5 per cent change in composition, the half-width of the distribution of guanine–cytosine residues in calf thymus deoxyribonucleic acid can be estimated as extending ± 5 per cent about the mean of 49 per cent guanine–cytosine.

With calf thymus deoxyribonucleic acid appearing to have a relatively broad distribution of composition, an attempt was made to recover undenatured deoxyribonucleic acid from a partially denatured sample and to see if it had a higher melting profile. A sample heated to 90°, corresponding to 80 per cent of the transition, was cooled and carried through two successive precipitations with streptomycin. The resulting sample exhibited a melting curve that was displaced 1·5 deg. higher than the calf thymus curve in Fig. 1. Thus, it is seen that components of different T_m are indeed contained within calf thymus deoxyribonucleic acid.

In a further experiment, calf thymus deoxyribonucleic acid was degraded sonically to one-twelfth of its original molecular weight. Its melting profile was then only very slightly broadened. This indicated that the heterogeneity observed here exists on a scale very much smaller than that of whole molecules.

The relatively small dispersion in the distribution of guanine–cytosine among the samples of bacterial deoxyribonucleic acid, viewed in conjunction with the very broad range of mean composition, leads to the interesting conclusion that there is essentially no overlap in the composition of the deoxyribonucleic acid molecules of many bacteria. This point is confirmed and discussed in the following communication.

The relation between the transition profile and the inactivation of the transforming ability of *D. pneumoniae* deoxyribonucleic acid has been examined in two ways. When this deoxyribonucleic acid undergoes extensive inactivation by ultra-violet irradiation, no significant changes in its macromolecular properties can be detected. However, the transition profile is relatively sensitive to irradiation, being shifted to successively lower temperatures. For example, at 10 per cent remaining streptomycin transforming activity, T_m is 1·5 deg. lower. Thus, what is generally considered to be a very small amount of chemical alteration can be detected by the alteration of the absorbance–temperature profile.

When the thermal inactivation of various genetic markers is compared with the transition profile, it is found that the inactivation generally lags behind to varying degrees. This may arise either from a partial reversibility of the transition, that is, a re-healing of some molecules that are only partially melted out, or from our happening to select markers that are carried by the deoxyribonucleic acid molecules having higher T_m values.

We wish to thank Miss D. Lane, Mr. J. Kucera and Mr. L. Matthews for essential contributions to experimental work presented here. We are grateful to Drs. J. Fresco and N. Sueoka for helpful discussions. This investigation has been supported by a grant from the U.S. Public Health Service, C-2170.

II. Dependence of the Density of Deoxyribonucleic Acids on Guanine–Cytosine Content

By Dr. NOBORU SUEOKA, Dr. JULIUS MARMUR and Prof. PAUL DOTY
Departments of Biology and Chemistry, Harvard University, Cambridge, Mass.

The discovery by Meselson, Stahl and Vinograd[1] of a technique of banding deoxyribonucleic acids in the density gradient established in the cell of an analytical ultracentrifuge has made possible the precise determination of the density of samples of deoxyribonucleic acid in microgram amounts. With this sensitive method available, it was of interest to see if a variation of density with guanine–cytosine content could be detected that would parallel that found for the denaturation temperature, reported in the foregoing communication. A systematic examination of samples of deoxyribonucleic acid having different guanine–cytosine contents showed that there was indeed a significant dependence. We wish to summarize these results here and to indicate the use of this effect in estimating the heterogeneity of composition in deoxyribonucleic acid samples and in studying the denaturation of deoxyribonucleic acid. The estimates of heterogeneity of composition for samples of bacterial deoxyribonucleic acid are unexpectedly small; the implications of this are briefly discussed.

The experimental technique employed was precisely that described by Meselson *et al.*[1]. About 3 μgm. of deoxyribonucleic acid was added to a concentrated solution of cæsium chloride (about 8 *M*) adjusted to the anticipated density. This was centrifuged in the 'Spinco' Model E ultracentrifuge at 44,770 r.p.m. at 25° C. for 24 hr. By this time the deoxyribonucleic acid had banded and its distribution in the band had become essentially constant. The distribution was recorded by photographing the cell using ultra-violet light and making a microdensitometer trace. As an illustration of the effect observed, Fig. 1 shows a photograph of a solution containing nearly equal amounts of four samples of deoxyribonucleic acid and the corresponding trace. The resolution of the four bands is evident. The results of a systematic study are shown in Fig. 2, where the density is plotted against guanine–cytosine content. It is seen that a linear relation is found; it corresponds to a change of 0·00103 in density per 1·0 per cent change in guanine–cytosine content. Since the uncertainty in determining densities in this way is about 0·001, it follows that the guanine–cytosine content of a sample of deoxyribonucleic acid can be determined from its density with a precision of about 1 per cent.

The extrapolation of the results for naturally occurring deoxyribonucleic acid to the extremes of the composition axis indicates that adenine–thymine deoxyribonucleic acid should have a density of 1·662 and guanine–cytosine deoxyribonucleic acid 1·764. The measured density for the former is 1·680. The difference may be attributed to the adoption of a slightly more compact structure when guanine–cytosine pairs need not be accommodated[2].

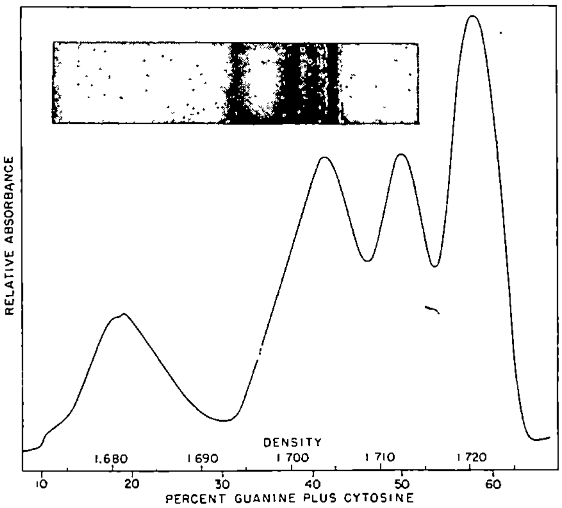

Fig. 1. Resolution of polydeoxy adenine–thymine and *Pneumococcus*, *E. coli* and *Serratia marcescens* deoxyribonucleic acids by density-gradient centrifugation. The photograph was taken after centrifugation at 44,770 r.p.m. for 24 hr. The tracing was taken with a microdensitometer in the region of the four bands. (The composition scale does not apply to the adenine–thymine deoxyribonucleic acid)

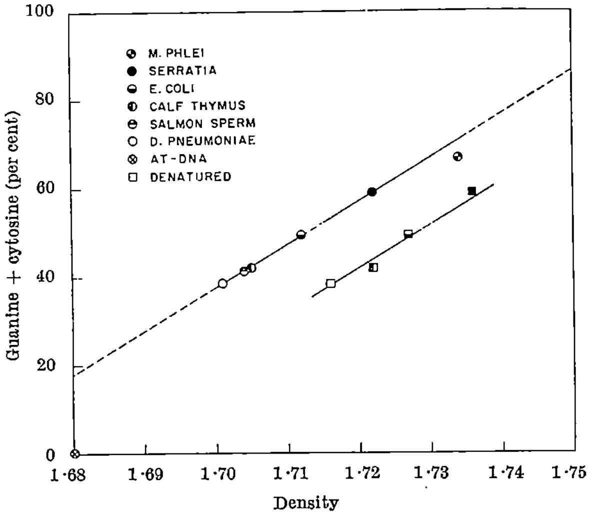

Fig. 2. Relationship of density to the guanine–cytosine content of various samples of deoxyribonucleic acid

At least half the observed dependence of density on composition can be explained by differences in the molar volumes of the two base-pairs as computed from atomic volumes. The failure to explain the entire difference in this way may lie either in errors inherent in deriving molar volumes from atomic volumes or from a small dependence of the atomic co-ordinates of the structure of the deoxyribonucleic acid on base-composition[2], or from an unequal binding of cæsium chloride ions by the two base-pairs.

Having found that the density of deoxyribonucleic acid depends on its composition, it follows that a heterogeneity of composition among the various deoxyribonucleic acid molecules of a given sample will be reflected in a broadening of the band. Molecules of uniform density are distributed in the band region as a result of thermal agitation. Meselson *et al.*[1] have shown that the square of the standard deviation, σ^2, that is, the variance, was inversely proportional to the molecular weight. However, if a distribution of density is superimposed upon the molecules, there will be a further broadening of the band. It will be useful to examine the relative importance of these two effects in a specific example.

Under the conditions employed, the relation between the molecular weight, M, and the variance is $M = 239{,}000/\sigma^2$, where σ is expressed in mm. Thus, in the absence of heterogeneity of density, deoxyribonucleic acid of molecular weight 8,000,000 would have $\sigma = 0{\cdot}172$ mm. The half-width of the band would be approximately double this distance, that is, 0·35 mm. Let us ask what heterogeneity of composition would have to be introduced to increase the band-width by $\sqrt{2}$, that is, to diminish the apparent molecular weight to 4,000,000. Since, under the conditions of these experiments, the density gradient $d\rho/dr$ was equal to 0·0122 mm.$^{-1}$, it follows that the formal dependence of composition on distance is $(d\rho/dr)/(d\rho/dX) = dX/dr = 0{\cdot}0122/0{\cdot}103 = 0{\cdot}1185$ mole fraction unit per mm. Since the σ due to heterogeneity of density must be equivalent to 0·172 mm., a standard deviation of 0·0204 mole fraction units is required in the distribution of composition to provide for an increase in the band width by $\sqrt{2}$. Thus, a distribution of guanine–cytosine such that the half-width of the distribution is 4 per cent on the guanine–cytosine scale would cause a sample of deoxyribonucleic acid having a molecular weight of 8,000,000 to appear to have a molecular weight of only 4,000,000. This degree of heterogeneity of composition lies in the range estimated from the analysis of the absorbance–temperature curves for bacterial deoxyribonucleic acid (see preceding communication). Consequently, the heterogeneity of composition encountered in samples of bacterial deoxyribonucleic acid can be large enough to affect appreciably the molecular weight calculated from band-profiles. Conversely, the band-widths observed for these samples of bacterial deoxyribonucleic acid are sufficiently small to set an upper limit to the heterogeneity in composition. Thus, even if the entire band-profile is interpreted in terms of density heterogeneity, we can conclude that this corresponds to a relatively narrow distribution of molecular composition about the mean composition. Our estimate of the heterogeneity in composition of calf thymus deoxyribonucleic acid is consistent with the fractionations that have been reported: however, only approximate comparisons can be made. The five fractions obtained by G. L. Brown and A. V. Brown[3] indicate a distribution having a little greater dispersion than that which we estimate. The three fractions obtained by Crampton, Lipshitz and Chargaff[4] as well as the selected fractions of Bendich *et al.*[5] show a somewhat smaller range (41–48 per cent guanine + cytosine). Our estimate for the heterogeneity of calf thymus deoxyribonucleic acid is that the σ-value is approximately equal to 0·06 mole fraction units; that is, the half-width of the curve of distribution against composition would extend from about 37 to 49 per cent guanine + cytosine. It is to this point that we shall return at the end.

In the absence of heterogeneity of density, the band-profile should be symmetrical. In samples of two mammalian deoxyribonucleic acids, calf thymus and mouse, pronounced skewness has been found. These are on opposite sides in the two cases. An unsymmetrical heterogeneity of density provides an obvious explanation for this effect.

With the means at hand for estimating the distribution of guanine–cytosine content among the molecules of a sample of deoxyribonucleic acid, it is of interest to see to what extent this heterogeneity is maintained within the deoxyribonucleic acid molecules. Since the distribution of composition is found to be relatively narrow, it would be expected that it would broaden as the molecules were degraded. Since sonic waves can be used to degrade deoxyribonucleic acid without denaturation[6], this problem may be approached as follows. We assume that the total variance of a band is equal to the sum of the variance due to thermal agitation and to the variance due to the distribution of density. If the molecular weight can be obtained for the original deoxyribonucleic acid and for one or more sonically degraded samples, the variance related to molecular weight can be computed. When this is subtracted from that found from the band-profile, the remainder should in each case be that due to the heterogeneity of density, and at sufficiently advanced degrees of degradation it should increase. In a preliminary experiment along these lines we degraded sonically calf thymus deoxyribonucleic acid from its original value of 8,000,000 to 620,000. The broadening of the band-profile was found to be actually somewhat less than that expected from the fall in molecular weight alone and, incidentally, the skewness remained.

Consequently, in this case we conclude that the distribution of composition found for the deoxyribonucleic acid molecules is preserved down to at least a tenth the original molecule.

When deoxyribonucleic acid is thermally denatured, the density increases. The results for four samples are plotted as square symbols in Fig. 2. The average increase of 0·015 compares very well with the earlier observation of an increase of 0·014 for two samples by Meselson and Stahl[7].

In an earlier study of thermal denaturation of calf thymus deoxyribonucleic acid[8], it appeared that the sample consisted of molecules having a range of individual denaturation temperatures, and this can now be interpreted as resulting from the distribution of guanine–cytosine. When partially denatured calf thymus deoxyribonucleic acid was examined in the density gradient, it was found that the band corresponding to the original deoxyribonucleic acid had diminished principally at the expense of material of low density, and that the new band which appeared had a lower density than completely denatured deoxyribonucleic acid. This behaviour clearly indicates that those molecules of relatively low guanine–cytosine content had become preferentially denatured. It has already been mentioned that the isolation of native deoxyribonucleic acid from such a partially denatured sample had a higher melting temperature (see preceding communication). When this fraction was examined in the density gradient, it was found to have a correspondingly higher density than the original deoxyribonucleic acid from which it had been isolated. Thus, the earlier views on the denaturation of deoxyribonucleic acid are confirmed and extended by recognizing explicitly the role of the guanine–cytosine heterogeneity.

In conclusion, we return to comment on the surprising finding that samples of bacterial deoxyribonucleic acid have a relatively narrow range of base composition, while the mean compositions show a wide variation. This stands in contrast to the nearly identical base compositions of mammalian deoxyribonucleic acid. The result for bacterial deoxyribonucleic acid is surprising, because it shows that bacteria having deoxyribonucleic acid density differences of 0·02 or more have essentially no deoxyribonucleic molecules with common composition. Since the metabolism and replication of bacteria do have much in common, it is generally thought that many of their proteins should be identical, or very similar. Yet all current discussions of the way in which deoxyribonucleic acid can control the sequence of amino-acids in protein requires a direct correlation between the composition of the deoxyribonucleic acid and of the protein.

Since it is often assumed that the information in deoxyribonucleic acid passes to the protein through ribonucleic acid, it is of interest to note that Belozersky and Spirin[9] have demonstrated that the variation in composition of bacterial ribonucleic acid is relatively small, but nevertheless it does show a significant correlation with the composition of the corresponding deoxyribonucleic acid for nineteen bacterial species.

It appears that the explanation of this dilemma with regard to bacterial deoxyribonucleic acid must lie with one of three possibilities.

(1) The proteins that perform common functions in bacteria may be structurally quite different in many cases. For example, in enzymes the active sites may be similar, but the main part of the proteins different. This is the situation that might be expected if the evolutionary development of bacteria has followed a number of independent paths, each corresponding to the elaboration of a complex genome from a primary deoxyribonucleic acid of a particular composition. In general, this view suggests that the distribution in composition of deoxyribonucleic acid molecules of organisms reflects their phylogenetic relationship.

(2) The proteins that perform common functions in bacteria are very similar structurally. If all the deoxyribonucleic molecules are genetically active and yet unrelated in composition in many cases, the coding between the deoxyribonucleic acid and the protein must be very different from those that have been considered hitherto[10]; that is, it has been customary to assume that the sequence of amino-acids (20) in proteins is coded in the sequence of the four nucleotides in deoxyribonucleic acid. Since it has been shown that various triplets of nucleotides are sufficient to specify each amino-acid, it follows that similar proteins must be derived from deoxyribonucleic acid molecules of similar composition, unless quite artificial, *ad hoc*, restrictions are imposed. If the coding concept is to remain, a radical revision is necessary in order to eliminate this dependence on composition. For example, the four-letter alphabet (adenine, cytosine, guanine, and thymine) could be abandoned in favour of a two-letter alphabet in which adenine and cytosine (6-amino-bearing nucleotides) would serve as one letter and guanine and thymine (6-keto-bearing nucleotides) would serve as the other. In this case no relation to composition would be expected. Of course, it would be possible to retain the four-letter alphabet if it were assumed that different codes applied to different bacteria, but this alternative is unattractive because it is most unlikely that different codes would yield the same number of amino-acids (20).

(3) The proteins that perform common functions in bacteria are very similar structurally, and the current ideas concerning the coding problem remain acceptable. This could only be true if the major part of the deoxyribonucleic acid was genetically inactive. The minor part of the deoxyribonucleic acid could then have a composition in common with the corresponding part of other bacterial deoxyribonucleic acid. It appears that this minor part would have to be less than 10 per cent of the whole to have escaped detection.

The proof, or even the disproof, of any one of these possibilities would be very enlightening.

We wish to thank Prof. M. Meselson and Mr. J. Kucera for help in the initial stages of this investigation. This work has been supported by grants from the U.S. Public Health Service, C-2170, and from the National Science Foundation.

NEWS and VIEWS

Geology at Exeter: Dr. Scott Simpson

Dr. Scott Simpson, at present lecturer in the University of Bristol, has been appointed professor of geology in the University of Exeter in succession to Prof. A. Stuart, who has retired (see *Nature*, 181, 87 ; 1958). After receiving his early education at Highgate School, Scott Simpson proceeded to Clare College, Cambridge, and in 1937 took the second part of the Tripos in geology, selecting the alternative papers in palæontology. His postgraduate training was at Frankfurt-am-Main, where the late Prof. Rudolf Richter set him the task of unravelling the structurally complex area of Devonian rocks between Mayen and Daun in the east Eifel. That success attended his efforts is clearly shown by the fact that Richter, rather characteristically, arranged for Scott Simpson to be formally awarded his doctorate by the University of Frankfurt-am-Main two years after the start of hostilities between Britain and Germany.

Scott Simpson was assistant lecturer in the Department of geology and mineralogy at the University of Aberdeen for the first two years of the Second World War before he was seconded for the next four years to the Department of Natural Philosophy, where he instructed Royal Artillery and R.A.F. cadets in elementary physics and also worked at the Radon Centre. He transferred in 1949 from a lectureship in geology at the University of Aberdeen to a corresponding academic post at the University of Bristol. Here during the past decade he has acquired a reputation as a recognized authority in Britain on the stratigraphy and palæontology of the Devonian rocks. His own researches in Devon, and those of his students, have already resulted in important correlations being made with Devonian rocks of parts of Germany, and the methods he has applied have resolved the complicated geology of large areas of Devon and Cornwall. Of recent years he has carried out pioneer work in the study of structures in sedimentary rocks due to burrowing organisms, and their interpretation in terms of the interplay of organic and sedimentary processes. His reputation extends beyond the British Isles and his researches are recognized in Germany, Holland and France.

The Editors regret that, due to difficulties in the printing industry, some sections of this issue of "Nature" have had to be curtailed

Development and Research Appointments at the Mond Nickel Co., Ltd. : Dr. W. Steven

Dr. W. Steven, superintendent of the Development and Research Department Laboratory of the Mond Nickel Co., Ltd., in Birmingham, is to be transferred on June 1 to the Development and Research Division of the International Nickel Co., Inc., New York, as director of research. He has also been elected an assistant vice-president of that company. Dr. Steven graduated in the University of Glasgow in 1939 and obtained his Ph.D. degree in 1942. After five years with William Jessop and Sons, Ltd., Sheffield, he joined the Mond Nickel Co. in 1947 as a research metallurgist. In 1955 he was appointed superintendent of the laboratory.

Dr. G. L. J. Bailey

Dr. G. L. J. Bailey has been appointed superintendent of the Mond Nickel Development and Research Department Laboratory in Birmingham in succession to Dr. Steven. He took a B.Sc. (Hons.) degree at the Imperial College of Science and Technology, London, in 1937 and obtained his Ph.D. in 1939. After working at the Admiralty Engineering Laboratory, West Drayton, he joined the British Non-Ferrous Metals Research Association, where he became deputy research manager. Since 1955 he has been superintendent of the Platinum Metals Research Laboratory of the Mond Nickel Development and Research Department at Acton.

Dr. W. Betteridge

Dr. W. Betteridge has been appointed superintendent of the Platinum Metals Research Laboratory of the Mond Nickel Development and Research Department at Acton in succession to Dr. Bailey. Dr. Betteridge graduated in physics at the University of Birmingham in 1931, obtained his Ph.D. in 1933 and his D.Sc. in 1958. After serving with Joseph Lucas, Ltd., and the Bristol Aeroplane Company, he joined the Mond Nickel Co. in 1947, where he has been concerned primarily with the development of high-temperature materials, at first in the Birmingham Research Laboratory and more recently as development officer in London.

Submarine Defence Research

In reply to a question in the House of Commons on April 29, the Parliamentary and Financial Secretary to the Admiralty, Mr. C. Ian Orr-Ewing, said that the North Atlantic Treaty Organization research centre on defence against submarines, which was being set up by SACLANT at La Spezia, would be financed, at least for the initial period, entirely by the United States, and was intended to augment the scientific effort devoted by the several Nato countries to anti-submarine warfare research. The centre would be concerned primarily with basic problems, but would also undertake some operational research. The number of British scientists and Royal Naval officers to be employed there was not yet settled, but the naval adviser on the Scientific Advisory Council which would direct the work of this unit would be the Chief of the Royal Naval Scientific Service.

Department of Scientific and Industrial Research : Lending Library

A list showing holdings of the Lending Library Unit of the Department of Scientific and Industrial Research of irregular serials being received from the U.S.S.R. and Bulgaria has been issued (pp. ii+90.

London : D.S.I.R., Lending Library Unit, 1959), the titles being arranged mainly in alphabetical order, using the Cyrillic alphabet. There is also a short list of serials received from Latvia, Lithuania and Estonia, published in the Roman alphabet. Besides an index of transliterated abbreviations of titles, arranged alphabetically, there is an alphabetical subject-list based on a broad framework of the Universal Decimal Classification. The items listed can be obtained by approved borrowers from the Science Museum Library, using loan requisition forms issued by that Library, but these should be sent direct to the Unit at 20 Chester Terrace, London, N.W.1.

The Royal Institution Library

THE Library of the Royal Institution, which contains about 65,000 volumes, is divided into five sections, comprising the old library—started in 1799 and including many of the early works of the great philosophers as well as books published up to 1857 and the notebooks, letters and papers of Count Rumford, Humphry Davy, Michael Faraday, John Tyndall and others ; the modern library—containing books published after 1857, arranged by the Gliss classification ; the lending library, devoted mainly to general and popular science ; the periodicals, of which 400 are currently received ; and the storerooms. Notes on the library and its catalogues, with a list showing the holdings of periodicals and serial publications currently received, are given in a pamphlet recently issued (pp. 28. London : Royal Institution, 1958).

Florida State Museum

THE Florida State Museum serves as a joint University–State Museum and its major functions are to assemble and maintain collections of cultural and natural objects ; to encourage research on this material ; and to disseminate knowledge by publications and display. The annual report for 1957–58 (pp. 20. Gainesville, Fla. : Florida State Museum, The University, 1959) indicates that these functions have been fully maintained. During the period under review the staff has concentrated on the improvement of display, and many new ideas and techniques, especially those including the effect of artistry in presentation, have been incorporated. The investigation of archæological sites that might have been damaged by road construction has continued.

Tetrahedron Letters

As a supplement to the journal of organic chemistry, *Tetrahedron*, the Pergamon Press (London and New York) has begun to issue fortnightly or monthly *Tetrahedron Letters*, in which short communications of interest to organic chemists will be published within a week or month of acceptance (subscription, post paid (air mail charges extra) : £7 or 20 dollars per annum for libraries, government departments and industrial establishments ; no extra charge for private subscribers to *Tetrahedron* who write direct to the publisher certifying that the subscription is for their personal use). The first number (pp. 35) was published in March and contains six short communications of an international character. This publication should relieve some of the pressure on other scientific journals and its high standard seems likely to ensure it the success it deserves.

Education of Instrument Technologists and Control Engineers

THE subject of Mr. J. F. Coales's presidential address on May 6 to the Society of Instrument Technology was well chosen. Having shown the growing need for larger numbers of control engineers and instrument technologists and having proved that in most industries to-day there is some form of automatic control, he proceeded to outline the types of courses suitable for the men in charge. His views on the education of control engineers coincide with those expressed by several speakers at the conference on Degree and Diploma Courses in Applied Physics, arranged by the Society of Instrument Technology in November 1956, particularly in his insistence upon a broad-based fundamental approach for the graduate. Appendixes to his address contained valuable information which could not be easily assimilated into the body of the address, and many will be particularly interested in Appendix 2, concerned with detecting elements, and Appendix 3, outlining syllabuses for the ordinary National Certificate in Instrument Technology. Appendix 2 contains some twenty-one examples out of more than two hundred listed in a recent report on "Detecting Elements" published by the British Scientific Instrument Research Association.

Cyanamid International : Technical Papers

CERTAIN technical papers prepared by the research workers of Cyanamid for presentation before various learned societies in the United States or for publication in the proceedings of technical institutions in that country are to be made available in Britain. These papers cover a wide range of subjects but fall roughly into three classifications : pharmaceutical, agricultural and industrial, these being the main spheres of activity in which the Cyanamid group of companies is engaged. From time to time lists are prepared showing details of the technical papers available for distribution. Readers who would like to receive these lists as and when they are issued should write to : Cyanamid International Information Service, 16 Bolton Street, London, W.1.

The Age of the Earliest Remains of Man

CERTAIN skeletal finds from caves in the dolomite formation of the Transvaal not far from Pretoria have been known for some time. Whether these are indeed the earliest known remains of true man or whether they must be considered as still prehuman remains a matter of controversy. The late Dr. van Riet Lowe described in *Nature* (175, 16 ; 1955) a series of chipped stones which he considered to be artefacts, so that the beings in question were tool-using creatures. But grave doubts have been cast on Lowe's opinion and the objects in question may be natural products. Their association with the skeletal remains is more than uncertain, and they are probably later in age. Nevertheless, these skeletal finds are of capital importance, particularly to the physical anthropologist, and it is especially important that the cave deposits containing the remains of the Australopithecinæ should be accurately dated. A detailed investigation by C. K. Brain has recently been published (The Transvaal Ape-Man - bearing Cave Deposits. By C. K. Brain, with an appendix by R. F. Ewer. Transvaal Museum Memoir No. 11. Pp. viii+131. Pretoria : Transvaal Museum, 1958). The book can be recommended as a clear, succinct and factual account of the problems involved. The first part comprises an account of dolomite caves in general and of their infilling. This part will perhaps be of greater interest to the geologist, but the prehistorian is unwise if he puts these matters completely on one side. Part 2 gives a detailed account of most of the known sites—Sterkfontein, Swartkraus, Kromdraai, Coopers *B*, and the Makapan limeworks. In a final chapter a correlation of the deposits in the various sites is given and their ages suggested. Using the Leakey fourfold system of pluviations, it would seem that these early beings must be assigned to a period between the Kageran and the Kamasian pluvials, that is to say, to the first inter-pluvial, except for Kromdraai, which is slightly younger and dates to the second pluvial period. If they are certainly human and an association with true artefacts can be proved, they are indeed the earliest remains of our species so far discovered. The appendix by R. F. Ewer lists the faunal remains found.

Bibliography on the Chemistry of Tobacco Smoke

"The Constituents of Tobacco Smoke: an Annotated Bibliography", edited by H. R. Bentley and E. G. N. Berry, is the third in a series of research papers published by the Tobacco Manufacturers' Standing Committee (pp. ii+49. London, 1959). This publication, with its attractive format, contains more than 600 references on tobacco smoke, drawn from the technical literature of the world on that subject. The earliest reference quoted is to a German work of the year 1826. There are eight sections, dealing with nicotine, bases, acids, phenols, hydrocarbons, neutral fraction, arsenic, and a miscellaneous section which includes such diverse components as trace minerals, carbon monoxide and free radicals. Each section is preceded by a short introductory comment. While nearly 200 substances are quoted as occurring in tobacco smoke, the editors wisely point out that the degree of precision with which identifications have been made is by no means uniform, so that some of the work reported is of questionable reliability. This publication should prove very valuable to workers in the field of tobacco carcinogenesis, where an active search for carcinogenic factors of human significance is under way, proceeding from the proposed causal hypothesis relating tobacco usage and human cancer. The minute quantities of traditional carcinogens of the aromatic hydrocarbon class found in cigarette smoke are unlikely to explain the proposed special carcinogenic environment of the cigarette smoker.

Books required for the "Oxford English Dictionary"

The Editor of the Supplement to the "Oxford English Dictionary" writes: "It has proved impossible to obtain copies of some works, now out of print, which would help in the preparation of the forthcoming Supplement to the 'Oxford English Dictionary'. Any readers who would be willing to give, sell or lend copies of any of the following are requested to get in touch with the Editor at: 40 Walton Crescent, Oxford.

"J. R. Carpenter, 'Ecological Glossary', 1938.
R. T. Glazebrook, 'Dictionary of Applied Physics', 1922–23.
Oliver Heaviside, 'Electrical Papers', 1892.
Henderson and Henderson, 'Dictionary of Scientific Terms' (we have edit. 6, 1957; earlier editions required).
B. D. Jackson, 'Glossary of Botanic Terms' (any edition).
'Radio Engineering Handbook' (edits. 1 and 2), 1933–35.
A. L. M. Sowerby, 'Dictionary of Photography' (we have the 18th edit., 1957 impression; earlier editions needed)."

Announcements

The Wenner-Gren Foundation for Anthropological Research has awarded Viking Fund Medals and Awards of 1,000 dollars to Prof. Raymond W. Firth (University of London); Prof. Henri V. Vallois (director of the Musée de l'Homme, Paris); and Dr. Jesse D. Jennings (University of Utah).

It was announced at a recent meeting of the British Section of the Louis Rapkine Association that the Cross of Chevalier de la Légion d'Honneur has been awarded by the French Government to Dr. G. E. W. Wolstenholme, director of the Ciba Foundation, in recognition of the work he is doing for international co-operation in medicine and science and more particularly for Anglo-French collaboration.

The Geological Society of London has awarded the Daniel Pidgeon Fund for 1959 in moieties to Dr. M. K. Howarth, who proposes to study the Alum Shales (Upper Lias) at Whitby with particular reference to the ammonite fauna, and to Dr. M. J. S. Rudwick, who proposes to undertake research into the functional significance of the morphology of fossil brachiopods.

Two open days will be held by the British Cast Iron Research Association during May 28 and 29. A number of special exhibits and demonstrations have been arranged. The first day is set aside for representatives of member-firms and for the Press, the second for representatives of Government departments, other research organizations, educational bodies, trade unions, users of iron castings, and others. Further information can be obtained from the Intelligence Department, B.C.I.R.A., Bordesley Hall, Alvechurch, Birmingham.

The fifth International Salon de la Chimie is to be held in Paris during June 18–29 in conjunction with the fifth Rubber and Plastics Exhibition, the eleventh Exhibition of Laboratory Equipment and Instruments, the fifth Exhibition of Chemical Engineering and Protection against Corrosion, the fifth Industrial Heating Exhibition, and the first Literature and Press Exhibition. Further details can be obtained from the General Secretariat of the Fifth Salon de la Chimie, 28 rue St. Dominique, Paris 7^e^.

The twelfth annual conference on Electrical Techniques in Medicine and Biology will take place in the Sheraton Hotel, Philadelphia, Pennsylvania, during November 10–12. It is sponsored by the Joint Executive Committee in Medicine and Biology, appointed by and representing the pertinent interests of the American Institute of Electrical Engineers, the Institute of Radio Engineers for its group on Medical Electronics and the Instrument Society of America. Proposals for papers are invited and should be submitted to Dr. L. E. Flory, RCA Laboratories, Princeton, N.J., before July 1. Such proposals should be 100–200 words in length, supplemented by a short biographical note, and include affiliation and company title.

Erratum. J. R. Hensler, Bausch and Lomb Optical Co., Rochester 2, New York, writes: "In my note, 'Synthesis of Colour Centres in Silica and their Thermoluminescence', published in *Nature*, March 7, p. 673, column 1, lines 3–6 should read: 'The quenching of the luminescence in the presence of the aluminium centres is evidence for the interaction of these and the ultra-violet absorbing centres'. The phrase 'in the presence' was omitted".

JOACHIM JUNGE (1587–1657)

A FORGOTTEN GENIUS

THE name of Junge, known also as Jung or Jungius, is to be found in few biographical dictionaries, and is seldom mentioned by historians of science. Nevertheless, his contribution to scientific thought and knowledge was significant and considerable. He lived at a time when alchemy became chemistry, astrology gave way to astronomy, and other sciences assumed a new appearance as the old scholastic approach to learning was replaced by a return to the use of experimental methods. Junge published little or nothing during his life-time, and for that reason his work has been overshadowed by that of his contemporaries. To-day, after a lapse of three centuries, his achievement is beginning to receive a well-merited recognition.

The main events of his career may be summarized as follows. Born at Lübeck in 1587, the son of a schoolmaster who died while his son was still a child, he was enabled, by the sacrifice and wisdom of a far-seeing mother, to enrol as a student at Rostock in 1606, and then at Giessen, where his brilliant intellect became so obvious that he was offered, and accepted, the chair of mathematics. This academic position did not afford him the scope for wider study which he desired, and in 1614 he resigned, and went to study medicine at Padua, where he graduated M.D. in 1618. On his return to Rostock he hoped to found an academy of sciences, and although he did succeed in establishing the Societas Ereunetica in 1622, one of the earliest societies of its kind, it survived for only two years. The reason of this failure was that Junge was suspected, though quite unjustly, of being a Rosicrucian, a member of the secret society of that time devoted to astrology. It was not surprising, however, that the progressive views of Junge, which included his advocacy of teaching in the vernacular, and of a greater use of experiment, brought him into disrepute with the Church. As a result of this misfortune, and the threat of an accusation of heresy, he removed to Hamburg, where he passed the last thirty years of his life as rector of the High School, and where he died on September 23, 1657.

Junge's opinions won the approval of Leibniz, who placed him on a level with Galileo, Kepler and Descartes, while Goethe said that if the methods of Junge had been followed sooner, the advance of human knowledge might have been hastened by a century. Unappreciated in his life-time, his service to science remained obscure. Like his contemporary, William Harvey, he lost many of his manuscripts in a fire, and the suspicion with which he was surrounded prevented the publication of those that remained. Unlike Harvey, Junge did not live to see the result of his labours. His disciples and followers recognized their merit, however, and among his works, printed during the century following his death, are "De plantis Doxoscopiae physicae minores" (1662), "Isagoge phytoscopia" (1678), "Logica Hamburgensis" (1681), "Geometrica empurica" (1688), and "Opuscula physica botanica" (1747).

Most of those books have become very rare, but during the succeeding years his memory has been kept alive by his admirers, and especially by those in Hamburg. On the 300th birthday of Junge in 1887, Dr. Konrad Friedlander reported that "in terms of the will of Joachim Jungius, about 500 scholarships had been awarded, for the furtherance of scientific work, and that the list of scholars included many distinguished persons". In 1928, Prof. Meyer-Abich, of the University of Hamburg, founded the "Jungius Kommission", with the view of investigating the unpublished manuscripts, and in the following year a commemorative volume was printed, entitled "Beitrage zur Jungius-Forschung". Eventually, in 1947, a "Joachim Jungius Gesellschaft" was inaugurated in Hamburg, with the wider object of "promoting research in all branches of science, and extending the scope of scientific work".

The year 1957, the tercentenary of his death, marked a further revival of interest. Dr. J. H. S. Green paid a graceful tribute to the memory of Junge in an article in *Nature* (180, 570; 1957), and when the Joachim Jungius Gesellschaft met at Hamburg on October 31, 1957, under the presidency of Prof. Kurt Heyns, his first duty was to award a Joachim Jungius Prize and Medal to its first recipient, Prof. Rudolf Meyer, of Zurich, who has long been an ardent student of the works of Junge, and had recently edited a new edition of "Logica Hamburgensis". Prof. Meyer than delivered an address on "Joachim Jungius and the Philosophy of his Time", which, following the introductory remarks of the president, is printed, with other noteworthy papers by various authorities, in the little volume commemorating the occasion, which bears the title "Die Entfaltung der Wissenschaft" (The Development of Science)*, and which may be read with pleasure and profit by every scientist, whatever be his special branch.

Prof. Kurt Vogel deals with "Mathematics in the Early Years of the Seventeenth Century". Prof. R. Hooykaas, of Amsterdam, in a paper on the knowledge of elements and atoms at that time, shows how Junge championed the atomic theory, and opposed the older philosophy, alleging that in spite of chemical changes, atoms retained their individuality. This paper concludes with the significant remark that "one free man can do more for science than a whole crowd of *Konformisten*". The important place of Junge in the history of botany is clearly revealed by Prof. Walther Mevius, who tells us that Junge's contribution to that science was probably his greatest achievement. He was indeed one of the founders of scientific botany, and to him we owe the terminology which was perfected later by Ray and Linnæus. Junge was the first to classify plants according to the varieties of their component parts. Many modern terms are of his coinage, and, as Charles Singer stated in his "Short

---

* Die Entfaltung der Wissenschaft: Zum Gedenken an Joachim Jungius (1587–1657). (Vorträge gehalten auf der Tagung der Joachim Jungius-Gesellschaft der Wissenschaften, Hamburg, am 31 Oktober/1 November 1957 aus Anlass der 300 Wiederkehr des Todestages von Joachim Jungius.) Pp. 160. (Glückstadt: Kommissions-Verlag J. J. Augustin, 1958.)

History of Biology", Junge "had a real insight for classification, grouping plants according to the formation of their flowers, and naming the groups Compositae, Labiatae and Leguminosae", names which still remain. The paper which follows, on "Experiment in the Medicine of the Seventeenth Century", gives an interesting account of this important epoch in medical history, and is contributed by Prof. J. Steudel, of Bonn. It is illustrated by eleven figures, showing some experiments of Harvey, de Graaf, Boyle, Mayow and others. Prof. W. Flitner, of Hamburg, describes the logic and philosophy of the period, and his colleague, Prof. D. K. Deitrich Schmidt, discusses the changing outlook of theology in the days of Junge.

The scope of this excellent collection of monographs is extended even more widely by a thoughtful and suggestive study by Prof. Karl Bauch, Freiburg, of the new approach to art, adopted by Raphael, Rubens and other artists in the opening years of the century under review. Twelve illustrations in this paper are of much interest. Finally, an appropriate background to the whole scene is provided by Prof. Otto Brunner in an essay on "Hamburg's Historical Position during the Lifetime of Joachim Jungius". This article, also appropriately illustrated, should prove valuable as a reference to the contemporary topography of the city. Too often, in writing of the history of science, this essential basis of social history is omitted. The Joachim Jungius Society is to be warmly congratulated on the publication of this timely and attractive little volume, which not only pays a fitting tribute to the work of a forgotten genius but also builds upon that work an edifice well worthy of so sound a foundation.

DOUGLAS GUTHRIE

EDUCATION IN THE AGE OF SCIENCE

IN a recent issue of *Daedalus* (88, No. 1 ; 1959), ten distinguished American correspondents examine different aspects of American education and their place in a rapidly evolving scientific and technological age. The articles are grouped in five pairs, each pair representing two different points of view regarding the same aspect of education. The problem of Prof. Sidney Hook and George N. Shuster is that of the general nature and ends of education. Prof. Hook holds that the ends are threefold : to produce skills, knowledge and loyalties. On all three aspects there is a difference of opinion. If 'skills' mean the ability to think, speak and write effectively, education must clearly aim at such skills ; but do they include skills of everyday living ? Here there are rigorists and latitudinarians. Regarding knowledge and loyalties, the differences go deeper. Prof. Hook is a secularist who believes that the only knowledge worthy of the name is that which is accredited by scientific method, and that even moral judgments are subject to empirical tests. Shuster believes that theology is the queen of the sciences, and that the most sure and important knowledge has another kind of certification altogether.

In the papers of the second group, Prof. Douglas Bush states the case for the humanities in education, and Prof. Ernest Nagel the case for the sciences. Both advocates recognize that both disciplines are essential but they differ about two points. Prof. Bush, concerned about the 'sophisticated vulgarity' of newspapers, best-sellers, radio, advertising and music, thinks that much of this is a by-product of science, partly through its technical applications, partly through the exaltation of science in the popular mind. Science has made 'mass civilization' possible, and 'the religion of commonness' that has resulted has been creeping out from news-stands and films into the schools and universities. Science provides the means by which a commercial civilization may exploit the mind more expertly, but no corresponding resistances against the shoddiness of mass values ; nor does it do anything to prevent the 'spiritual impoverishment of the expert' himself.

Prof. Nagel, admitting the part of science in helping to produce mass culture, replies that it is unjust to make science responsible for men's misuses of it, and argues that our mass culture, for all its defects, represents a high-water mark in democratic education. He then makes a claim for science that provides a second bone of contention, believing that scientific method, taken broadly as the method by which propositions are validated, is the sole and sufficient means of establishing any kind of knowledge. The judgments of value passed by a humanist upon poetry or music may be merely expressions of his feeling ; but if they say more than that, if they offer themselves as true, there is only one way of establishing them, and that is the approved way of science. Bush, Shuster and others do not agree. They hold that the poet, the religious man, and the critic have insights that such a method is inadequate to appraise. Here, as elsewhere, it becomes clear how difficult it is to talk about education without entering into philosophy.

The chief issue of the third group is raised by Prof. Arthur Bestor's contention that American schools are trying to do too much. If all three ends —skills, loyalties and intellectual discipline—are important, can a school sensibly try to achieve all of them ? Perhaps a residential school can, since it has full control of the pupil's time. A day school cannot ; if, with a few hours a day at its disposal, it tries to take over the functions once performed by home, church and work, as well as to discipline the young mind, it will do all of them badly. Prof. Bestor's proposal for American schools is clear-cut : let them realize that they are over-extending themselves and close their ranks, so that they can perform their own function well—that function being distinctively intellectual. To maintain their standards in the face of local pressures, they should set up State-wide systems of examination, which would free the able students from the educational 'lock step' and would test actual achievement rather than accumulations of credits and hours.

Prof. Bestor's views are challenged at several points by Prof. John L. Childs, who argues that the sensitivity of American schools to the social needs of their pupils is an advantage, not a weakness, and that the schools are not to be improved by a return to the narrow intellectualism of the French and other systems.

The issue raised by the two papers in the fourth group is : What can the schools do to prepare their students for the sort of citizenship demanded by the United States' new place in the world ? Dr. Reinhold Niebuhr tries to make this new place clear. It is one in which three new conditions prevail : America has become the acknowledged leader of the free world ; is faced with a powerful and resolute rival ; and must apparently live with a 'nuclear stalemate'. In this precarious position, technology is no doubt important ; but Dr. Niebuhr thinks that an understanding of Russian imperialism and the curious American 'anti-imperialist imperialism' is equally so. It is necessary to have representatives abroad who speak the languages and understand the cultures of those among whom they are living ; and though there is no study that will enable one to forecast the future, the study that does most to equip one for understanding the larger problems of the day is history.

Hans Morgenthau puts his emphasis in a different place. Agreeing that history is important, he thinks it could best be taught and understood not as a string of events but as the exemplification of principle, and above all, the principle that nations seek power. A thorough grasp of this principle, as exemplified historically, would throw more light on the present scene than any study of the events or personalities of the day.

The fifth group of articles examines the social matrix within which education in the United States operates. Prof. Margaret Mead looks into the reasons for the separation between the world of the scientist and that of his intended audience, the general population. In this way she points to the mechanism that may be responsible for the widening of the gap between the intellectual and society at large. Prof. David Riesman directs attention to the medium in which the academic himself grows and moves—lest educators seek the sources of their difficulties only outside the sphere of their own organizational setting.

Most of the papers have been edited by Prof. Brand Blanshard, who has also contributed an introduction to them. For background, this special issue of *Daedalus* also contains a reprint of A. N. Whitehead's famous essay on "The Aims of Education", which was first written some forty years ago. For those concerned with education, this essay may serve the purpose of periodic re-dedication as well as any other source.

PUBLIC LIBRARIES IN ENGLAND AND WALES

THE report of the Committee appointed by the Minister of Education in September 1957 to consider the structure of the public library service in England and Wales* reviews briefly the development of the public library service and the changing views of its functions, particularly the changes in formal structure since the Kenyon Committee reported in 1927. Turning then to the public library service to-day, it suggests that three main questions arise : how a really adequate service throughout the country can best be provided ; the standards for judging the efficiency of a library service ; and the requisite conditions which will enable a local authority to provide an efficient service. Chapters on the future structure of public library administration, library co-operation, staff and premises, the position in Wales, library charges and library legislation follow.

The principal recommendations are that the Minister of Education, assisted by two advisory bodies for England and Wales, respectively, should exercise a general responsibility for the public library service, with powers to enforce the discharge of its statutory duty by any library authority he considers to be in default. Every public library authority should have a statutory duty to provide an efficient library service, and the minimum annual expenditure on the purchase of books expected from a non-county borough or urban district council as an independent library authority should be £5,000 or 2*s*. per head of the population. All library authorities should be given powers to appoint library committees directly responsible to the councils.

The existing regional committees should be given statutory recognition and required, under schemes approved by the Minister, to provide a satisfactory system of library co-operation within their regions and to work in conjunction with the National Central Library. The local authorities should contribute substantially to the cost of the National Central Library, with greater representation on its governing body and in its administration. An adequate series of regional catalogues and the catalogue at the National Central Library should be completed as a matter of urgency and with a non-recurrent Treasury grant. Extra-district charges should be abolished for readers using libraries outside their own areas. Salary scales for the staff of public libraries should be commensurate with their qualifications and responsibilities and so applied as to make career prospects attractive. To meet the need for considerable improvement in public library premises and for many new library buildings a higher priority should be given to capital expenditure for this purpose. No charge should be made to borrowers of books or other material except for notification that the book or material is available or for retention beyond a prescribed period, and legislative provision should be made authorizing the levying of these charges by library authorities.

A new Public Libraries Act should be passed to give effect, so far as is necessary, to these recommendations and giving all library authorities specific powers to combine or co-operate with each other, and with education and other authorities, to provide lectures and cultural activities, to provide and lend such material as gramophone records and films and to acquire land compulsorily for library purposes under the Act. It is also recommended that the position of local authorities responsible for museum and art galleries should be considered, since it may be necessary to legislate separately for libraries, museums and art galleries in future. A minority report by Mr. J. Bulman and Mr. S. J. Skillen enters reservations as to the type of local authority which should become or remain library authorities and dissents from the suggestion as to a minimum expenditure on books.

THE NATURE OF COAL

A SYMPOSIUM on the nature of coal was held at the Central Fuel Research Institute, Bihar, during February 7–9. The delegates were welcomed by Dr. A. Lahiri, director of the Institute, and by Prof. M. S. Thacker, director-general of scientific and industrial research in India, who referred to the valuable work already done by the Institute and to the need for symposia to review progress and exchange ideas. Dr. B. C. Guha of University College, Calcutta, gave the inaugural address. Coal, he said, was the parent of the industrial revolution and our principal source of heat and power. With the advent of atomic energy, some people feel that the use of coal as a fuel will decrease. Even if this were true, however, coal will still remain the source of numerous organic compounds—dyes, drugs, plastics and explosives. After less than a century of research on coal there remains much to be learnt and, no doubt, many new materials and processes to be developed.

The main subjects of the symposium were the origin and formation of coal; petrographic studies; X-ray structure; the constitution of coal as revealed by physical methods or by chemical methods; and the physico-chemical properties of coal. Contributions were received from a number of foreign countries, including Great Britain, the U.S.S.R., Japan, the United States, Canada, Australia, New Zealand, Czechoslovakia, Belgium, and West Germany.

In the session dealing with the origin and systematics of coal, the opening paper, by Dr. A. Lahiri, was on the metamorphism of coal, that is to say, on the transformation of vegetable matter and peat to lignite, bituminous coal and anthracite. This is referred to again later. In addition, there were interesting contributions from certain Russian investigators, namely, W. Rakovsky on the processes of formation of fuels and ways of solving the general problem of genesis, N. M. Karavayev on the early stages of formation of fossil fuel, A. Z. Yurovsky on the theory of the origin of sulphur in coals, V. S. Veselovsky on the chemical nature of caustobioliths from the point of view of genesis, and V. I. Kassatochkin on the physico-chemical aspects of the metamorphism of coals. There was also a well-discussed paper by A. Gillet and P. Colson on petroleum and anthracite from cellulose. Prof. Gillet, in presenting this paper, first dealt with the earlier work on the subject and later expounded his theories of the development of the main liquid and solid fuels from cellulose, employing numerous diagrams for illustration.

In the following session, papers were presented on petrographic studies on Indian coals and their relation to certain chemical properties, the significance of X-ray studies in the elucidation of problems of coal formation, deductions from recent X-ray data on coals, X-ray studies on oxidized coals and humic acids. On the ultra-fine structure of coal, the contributions were made on the sorption properties and structure, on the relation between internal surface and functional group measurements, on the adsorption of krypton by coal, and on the porosity of coal and of carbonized products as revealed by densities using helium and mercury as the displaced liquid. Considerable interest was shown in 'heat of wetting' and in the significance of the results obtained by different methods of determination.

In the papers and discussions on physical methods of studying the constitution of coals, the nine steps of Seyler did not receive support from T. N. Basu and D. Bagchi in their work on reflectance. Definite changes of reflectance, however, were confirmed at 85 per cent carbon and at 90–91 per cent carbon. Indeed, the changes when the carbon of coal exceeds 85 per cent were noted by many contributors from different sources. These changes are reflected in natural moisture, density, calorific value, oxygen, and coking properties, and seem to be related broadly to the elimination of hydroxyl groups in a drastic and abrupt manner involving re-orientation of molecular structure, probably with formation of quinone linkages. In India the mine dusts from such coals (85 per cent carbon) seem particularly dangerous in respect of mine explosions.

J. D. Brooks (Australia) presented a useful review of the principal chemical methods of investigating the constitution of coals, covering the results obtained by the various methods of determining functional groups, oxidation reactions, hydrogenation, hydrogenolysis, sulphonation, hydrolysis and pyrolysis of coals. J. B. Stott (New Zealand) dealt with the effects of evaporation on the early stage of spontaneous combustion of coal. Problems of coal heating have often presented baffling inconsistencies in the past: many of these could probably be explained by the influence of evaporation of water.

L. D. Ahuja and others, in discussing the conversion of non-coking coal to coking coal by partial hydrogenation, considered that the improvement in coking property is largely bound up with the removal of the more stable oxygen linkages. Drs. P. N. Mukherjee and A. Lahiri, dealing with the constitution of humic acids, pointed out that, on the basis of X-ray and infra-red studies, there is a close similarity between the structural units of coal and humic acids. From studies of various properties, including ultimate composition, molecular weight, equivalent weight and the distribution of functional groups, a tentative structural model was suggested for humic acids.

M. S. Iyengar and others claimed that with high-sulphur coals (up to 6 per cent organic sulphur) there are three different types of sulphur, namely: (1) sulphur eliminated during the initial stages of oxidation; (2) sulphur oxidized to sulphonic acids; and (3) sulphur resistant to oxidation. The first type has not been identified, the second has been identified as thiophenol, while the third is tentatively assumed to be thiophene.

A striking paper was given by B. K. Mazumdar and his colleagues on dehydrogenation studies carried out on several coals of different rank, on vitrains, on oxidized and weathered coals, and on coal extracts and pitch. They had used Vesterberg's technique. The optimum temperature for dehydrogenation with sulphur was found to be 200°–360° C. for bituminous coals and lignites. (Anthracite reacts with sulphur only above 480° C.) The hydrogen sulphide evolved accounts for more than 92 per cent of the products of reaction, but small amounts of methane are also detected. Dehydrogenation under these conditions was ascribed primarily to the presence of alicyclic (hydro aromatic) structures, and the amount present was measured by the hydrogen sulphide formed. This was confirmed by a hydrogen balance of the coal and its dehydrogenated products. It was shown that 'alicyclicity' progressively diminished with rank, from 25 per cent in lignite to almost nil in anthracite. Similarly, alicyclicity with respect to hydrogen (Hal/H) varied from 60 per cent in lignite to nil in anthracite.

Further dehydrogenation of coal resulted in complete destruction of coking properties, inhibition of the formation of tar, and higher yields of char—apparently at the expense of the tar bodies. The yield of low-temperature tar was found to be proportional to (and also nearly equal to) the alicyclic carbon in coal.

Prior dehydrogenation led to the retention of 90 per cent of the original carbon of coal in low-temperature carbonization char, whether employing lignites or bituminous coals, whereas in normal (high-temperature) carbonization only 70–80 per cent of the carbon of the same coals was retained. The 'extra' carbon retained as a result of dehydrogenation and subsequent pyrolysis was considered to be a measure of the alicyclic carbon and hence of alicyclic hydrogen. A simple test of volatile matter in the presence of sulphur or selenium would afford a direct estimate of the alicyclic carbon retained in the char.

B. K. Mazumdar and his colleagues also explained the influence of the alicyclic component on the behaviour of coal in coking and tar formation, spontaneous combustion and weathering. Knowledge of the alicyclicity of coal enabled one to compute the aliphaticity, which was practically constant for all coals at 9–10 per cent of the carbon.

In a paper on aliphatic hydrogen in coal, J. N. Bhowmick and his collaborators described experiments employing chlorination to determine the aliphatic groups. Exhaustive chlorination of the coal at 200° C. was followed by hydrolysis in potassium hydroxide solution, and on the basis of the estimation of the functional groups formed in the hydrolysed products, as well as the loss of carbon sustained during chlorination, the distribution of aliphatic groups in coals of different ranks was worked out.

F. Kaiser, H. S. Rao and A. Lahiri, reporting on the disposition of methyl groups, described work in which they first formed an estimate of the side-chains in coal by the application of Kuhn–Roth's procedure for the determination of $C\text{–}CH_3$ groups. (The method depends on the fact that every side-chain contains one, and only one, methyl group, and that every methyl group can exist only as the terminal carbon of a side-chain.) The variation of $C\text{–}CH_3$ content with increase in rank was studied, and a free radical mechanism postulated for the coalification process. The mechanism attempts to explain two important facts associated with the metamorphism of coal, namely, the increase in aromaticity and the evolution of methane during the coalification process.

Dealing with pyrolysis and its relation to the structural parameters of coal, B. K. Mazumdar, S. K. Chakrabartty and A. Lahiri showed how, on a basis of recent knowledge obtained from X-ray and infra-red studies on carbonized coal (and in the light of oxidation and dehydrogenation studies on coal and its carbonized products), a mechanism could be worked out for the pyrolysis of coal up to 600° C. Low-temperature (600° C.) coke or char, they claimed, is entirely aromatic in character and no aromatic carbon of coal is lost by carbonization at 600° C. The primary bodies of tar come mainly from the alicyclic component, whereas the hydrocarbon gases come from the aliphatic structures. Correlation was shown to exist between the yield of gas and aliphaticity.

N. Berkowitz, in dealing with the decomposition and diffusion processes in coal pyrolysis, claimed that the classical interpretation attached to the weight-loss – temperature curve (namely, that it indicates a slow and extended chemical decomposition) is at variance with experimental facts. Such curves, if interpreted in the light of a diffusion process, offer material from which several important conclusions about the nature and kinetics of the pyrolytic processes can be drawn.

The broad picture that emerged from the papers and discussions was that coal can be regarded as essentially a binary mixture of aromatics dispersed in non-aromatics via carboxyl groups. Fusain (long attributed to forest fires) was probably one of the primary stages in coal formation.

Summarizing and following Lahiri on the metamorphism of coal, the general trend in the changes from peat to lignite, and bituminous coals, is primarily one of dehydration. At certain stages this dehydration seems to occur in discrete steps, notably at about 70, 85 and 91 per cent carbon. With increasing enrichment in carbon there is a diminution in the water-holding capacity of the material, representing a change from 'sol' to 'gel'. At the lignite stage there occurs an increase in hydroxyl groups, both alcoholic and phenolic, with some carboxyl groups, but quinone and carbonyl groups are relatively scarce. Some of the coal carbon—about 20 per cent—is present as alicyclic compounds, but about 60 per cent is in the form of aromatic compounds. This complex colloidal gel in lignite is still dispersed in water. The dispersing phase (water) is not merely absorbed physically in pores or micropores, but is largely held to the organic mass by chemisorption or hydrogen bonding and polar absorption. When the moisture falls to 15 per cent or so, the sub-bituminous or ligno-bituminous stage is reached, but the alicyclicity and aromaticity are largely unaffected. The oxygen and moisture in the dispersed phase are reduced, largely through dehydroxylation and decarboxylation, but dehydroxylation still continues up to 84–85 per cent carbon. Here, however, there is a marked change in capacity moisture and coking properties, reflected in changes of hardness, elasticity, calorific value and resistance to weathering. The reflectance and refractive index are also increased: alicyclic carbon increases, and also the yield of tar. Thus, the sol-to-gel transformation is complete and the stage of true bituminous coking coals reached. Under X-ray diffraction the structure of the coal showed an apparent emergence of order from previous disorder, but there is no definite evidence of any appreciable increase in the number of rings (averaging 4 or 5): the aromatic nucleus does not grow, although the coal becomes predominantly aromatic. Alicyclic carbon falls to 10 per cent of the coal, but is of great value in providing the 'coking constituents' of Bone and Fischer. Coking coals consist of aromatic ring structures dispersed in alicyclic carbon structures. In Nature such changes are apparently brought about by high tectonic pressures with considerable evolution of methane, especially when the carbon rises from 85 to 87 per cent.

Finally, in anthracites, the 'ordered' carbon is involved: there is an abrupt rise in reflectance and in aromaticity, with changes in general appearance including the elimination of banding and petrographic heterogeneity. Coking properties are destroyed, and there is a small but definite rise in moisture content. The hydrogen content falls by 25–50 per cent of its earlier value. Apparently the organic gel has been transformed into an organic crystalloid. The process is thus primarily dehydration followed by decarboxylation, dehydroxylation and demethylation. The original aromatic carbon groups are not much affected by geochemical and geological changes until the 91 per cent carbon rank is reached. It is the variations in the alicyclic and aliphatic bodies which are largely responsible for the different types of coal, especially of bituminous coal.

The proceedings of the symposium are to be published in book-form.

J. W. WHITAKER

ROLE OF POLY-β-HYDROXYBUTYRIC ACID IN THE ASSIMILATION OF ORGANIC CARBON BY BACTERIA

By PROF. M. DOUDOROFF and PROF. R. Y. STANIER

Department of Bacteriology and Miller Institute, University of California, Berkeley

IN 1936, Barker[1] observed that resting cells of a colourless alga, *Prototheca zopfii*, assimilate a large fraction of the carbon of the organic substrates which they oxidize. The same phenomenon was soon shown to occur in bacteria[2,3], and for some years the study of 'oxidative assimilation' had a considerable vogue among bacterial physiologists. The relevant literature has been reviewed by Clifton[4]. The discovery of the nature of bacterial photosynthesis by van Niel[5] in 1931 was followed by studies on the photosynthetic metabolism of organic substrates by the purple bacteria, which showed that under anaerobic conditions in the light these organisms can perform a very effective assimilation of organic carbon[6–8].

The work which has been done on the oxidative and photosynthetic assimilation of organic compounds by bacteria has thrown little light on the mechanism of the process. A dependence on the simultaneous formation of adenosine triphosphate is indicated by the observation that uncouplers of oxidative phosphorylation such as 2,4-dinitrophenol may prevent oxidative assimilation at levels which do not diminish the rate of respiration. From a study of the oxidative metabolism of specifically labelled radioactive substrates by *Pseudomonas saccharophila*, Wiame and Doudoroff[9] concluded that acetyl fragments are the intracellular metabolites that undergo assimilation.

It is furthermore evident that assimilation is not necessarily coupled with general cellular synthesis and growth, since bacteria can assimilate organic carbon with unimpaired efficiency in the absence of a nitrogen source. Under these conditions, the flow of carbon into the nitrogenous constituents of the cell must be negligible, and it could therefore be expected that the assimilated carbon accumulates in a limited group of cell materials. The evidence on this question is scanty and not clear. Gaffron, who first studied the photosynthetic assimilation of organic compounds by resting cells of purple bacteria[6,7], postulated the existence of a primary assimilatory product with the empirical formula $(C_4H_6O_2)_n$, and succeeded in isolating small quantities of a polymeric substance with this elementary composition from cultures grown photosynthetically on butyrate. Further pursuit of this lead seems to have been discouraged by van Niel's report[10] that the gross composition of the cells of purple bacteria corresponds closely to the composition of Gaffron's postulated assimilatory product, and the problem has remained where Gaffron left it in 1935. Inconclusive results have been obtained in the search for products of oxidative assimilation by resting bacteria. Wiame and Doudoroff[9] were unable to identify the radioactive cell-constituents formed by *Pseudomonas saccharophila* at the expense of substrates labelled with carbon-14, and suggested tentatively that the assimilated carbon flowed into many different cell materials, including proteins. Recently a similar conclusion was reached by Morita[11], who studied the dark oxidative assimilation of acetate, labelled with carbon-14, by *Rhodopseudomonas palustris*.

In 1927, Lemoigne[12] discovered that a polyester of β-hydroxybutyric acid is a major component of the cells of *Bacillus megaterium*, and the same substance was later found in other *Bacillus* species[13]. There is a considerable literature on the properties and metabolic behaviour of poly-β-hydroxybutyric acid in the genus *Bacillus*[12–20], and the accumulated evidence suggests that it functions as an intracellular reserve of carbon and energy for these bacteria. The recent observations of Macrae and Wilkinson[20] provide particularly convincing support for this hypothesis. The possible relevance of the investigations on poly-β-hydroxybutyric acid to the more general problem of bacterial oxidative and photosynthetic assimilation has been overlooked, no doubt because this polymer appeared until recently to be confined to a few species of bacteria. It was found in *Azotobacter* many years ago[21]; but its widespread occurrence in Gram-negative bacteria was first demonstrated in 1958 [22]. It has not been detected in any other group of micro-organisms, or in higher plants and animals.

The observation by our colleague Dr. Germaine Cohen-Bazire that purple bacteria accumulate massive quantities of poly-β-hydroxybutyric acid during photosynthetic growth on certain organic substrates prompted us to investigate its role in bacterial assimilation. We have examined the products of oxidative assimilation from glucose, acetate and butyrate in *Pseudomonas saccharophila*, and of photosynthetic assimilation from acetate and butyrate in *Rhodospirillum rubrum*. In all cases, a major fraction of the assimilated carbon (60–90 per cent) initially accumulates within the cell as poly-β-hydroxybutyric acid; when the external substrate is removed, there is a fairly rapid intracellular breakdown of the stored polymer. These observations suggest that poly-β-hydroxybutyric acid may have a general physiological function in bacteria as a primary product of carbon assimilation, its role in bacterial metabolism being analogous to that of

Table 1. PHOTO-ASSIMILATION OF LABELLED ACETATE AND BUTYRATE BY *Rhodospirillum rubrum*

starch and glycogen in the metabolism of other organisms. Past failures to discover the polymer in bacteria (such as *P. saccharophila*) where it is a major component of the cell are readily understandable in view of its chemical properties. It represents a type of cellular constituent which is not detectable by the standard analytical procedures used for the fractionation of cell materials. Applied to cells which contain the polymer, these standard procedures result in the inclusion of the polymer with the protein fraction.

Isolation and Estimation of Poly-β-hydroxybutyric Acid

The poly-β-hydroxybutyric acid synthesized by *P. saccharophila* and *R. rubrum* is contained in sudanophilic cytoplasmic granules, similar to those of *Bacillus megaterium*[19]. These granules were isolated by digestion of the cells with alkaline hypochlorite[19], sedimented by centrifugation and washed with water. They were then treated with acetone and ether in order to remove lipids, after which the poly-β-hydroxybutyric acid was extracted with chloroform, dried and weighed. Such material is designated as 'polymer fraction' in the experiments described below. The poly-β-hydroxybutyric acid from each species was further purified by fractional precipitation from chloroform extracts with acetone/ether (2 : 1, v/v). The solubility properties, melting point and infra-red spectrum of the polymer from *P. saccharophila* and *R. rubrum* agree with those of the polymer from *Bacillus* spp.

Metabolic Role of Poly-β-hydroxybutyric Acid in *R. rubrum*

Polymer formation by *R. rubrum* at the expense of uniformly labelled acetate and butyrate was investigated. Cultures were grown at 30° C. in the light in Hutner basal medium[33] supplemented with either 0·01 *M* acetate or 0·005 *M* butyrate, and continuously aerated with 95 per cent nitrogen–5 per cent carbon dioxide. The cells were harvested by centrifugation, resuspended in Hutner phosphate buffer[24], and maintained in the light at 30° C. in a continuous stream of 95 per cent nitrogen to 5 per cent carbon dioxide for 12–16 hr., in order to deplete the internal polymer store. An initial sample was then taken, radioactive substrate was introduced, and the aeration mixture was changed to 95 per cent helium–5 per cent carbon dioxide in order to prevent nitrogen fixation. When most of the radioactive substrate had disappeared from the suspending medium, the cells were harvested by centrifugation, washed and resuspended in a small volume of distilled water. Dry weights of cells and polymer were measured on initial and final samples, and radioactivities on the final sample. The results are shown in Table 1. For ease of comparison, the actual data have been recalculated on the basis of an initial dry weight of cells of 1,000 mgm. In the experiment on acetate assimilation, the cellular dry weight increased by 594 mgm., and the polymer fraction accounted for 329 mgm. of this increase. The quantity of polymer carbon in the cells increased by 184 mgm., and the weight of carbon-14 incorporated from acetate in the polymer fraction was 174 mgm. From this it follows that acetate carbon flows into polymer without appreciable dilution, either by pre-existing cellular carbon, or by fixation of carbon dioxide. The experiment on assimilation of butyrate gave similar results; but somewhat less of the assimilated butyrate carbon was incorporated in polymer (58 per cent of the total, in contrast to nearly 70 per cent of the total in the case of acetate), and the dilution of radioactivity was appreciably greater.

The cells which had become radioactive as a result of assimilating labelled acetate or labelled butyrate were used for experiments on the subsequent fate of the polymer. The washed cells were resuspended in Hutner phosphate buffer supplemented with 0·1 per cent ammonium chloride, and illuminated for 12 hr. without an exogenous organic carbon source in a constant stream of 95 per cent nitrogen and 5 per cent carbon dioxide. Additional aliquots of the cells labelled from butyrate-^{14}C were similarly treated, but were furnished with an exogenous organic carbon source (either butyrate or succinate). At the end of the period of illumination, the cells were harvested, and radioactivities and dry weights of the cells and the polymer fraction were again determined. The results are shown in Table 2. In the absence of an exogenous organic carbon source, more than 90 per cent of the stored polymer disappeared, but a substantial part of the carbon-14 initially present in the polymer fraction remained in the cells. This fact shows that the polymer can serve as an endogenous carbon source for the synthesis of other cell-constituents. The cells provided with an exogenous

Exp. 1 performed with cells which had assimilated labelled acetate. Exp. 2, with cells which had assimilated labelled butyrate.

supply of butyrate increased in dry weight by about 30 per cent, and in polymer content by about 10 per cent. In this case, the loss of carbon-14 from the polymer fraction was relatively small, and almost identical with the total loss of carbon-14 from the cells. It is thus evident that the continued presence of exogenous butyrate greatly reduces the internal breakdown of polymer, and impedes its transfer to other cell-constituents. The effect of an exogenous supply of succinate is strikingly different. Under anaerobic conditions in the light, succinate is not used by *R. rubrum* for polymer synthesis, although it is an excellent substrate for growth. The cells furnished with succinate increased their dry weight by almost 40 per cent; but the succinate conferred no protection on the polymer pool, which disappeared to the same extent as in cells not furnished with an exogenous organic carbon source, and with a similar amount of transfer to other cell-constituents.

Metabolic Role of Poly-β-hydroxybutyric Acid in *P. saccharophila*

Washed cells of *P. saccharophila* strain *G* grown on mineral-glucose medium[25] were resuspended in 0·03 *M* phosphate buffer (*p*H 6·8). An initial sample was taken, uniformly labelled glucose-^{14}C at a final concentration of 0·4 per cent was added, and the suspension was shaken in air at 30° C. for 100 min. During this time, almost half the glucose was metabolized, and about 21 per cent of the glucose carbon which disappeared from the medium was incorporated in the cells. The cells were harvested and analysed as already described for *R. rubrum*. The results (Table 3) show that 66 per cent of the glucose carbon assimilated was incorporated in the polymer fraction, and that glucose flowed into polymer with very little dilution of specific activity.

Table 3. Oxidative Assimilation of Labelled Glucose by *Pseudomonas saccharophila*

	Cells	Polymer fraction
Initial dry weight (mgm.)	1,000	144
Increase in dry weight (mgm.)	193	144
Increase in polymer carbon* (mgm. C)		81
^{14}C incorporated (mgm. C)	112	74

* Calculated for $(C_6H_4O_2)_n$ from the increase in dry weight.

The assimilation of glucose observed in this experiment was much less than that customarily observed in manometric experiments, conducted with starved cells which are allowed to metabolize very small quantities of substrate[26,27]. Accordingly, a series of experiments on polymer formation under conditions comparable to those employed in the earlier manometric studies on assimilation by *P. saccharophila* were undertaken. Cells were grown on media with a mineral base, supplemented with the carbon source to be used in the subsequent experiment. They were harvested, resuspended in phosphate buffer, and shaken in air for 16 hr. at 30° C. in order to deplete their endogenous reserves. These starved cells were then permitted to oxidize a small quantity of substrate uniformly labelled with carbon-14, the course of the oxidation being followed manometrically. As soon as the uptake of oxygen indicated that substrate utilization was approaching completion, the cells were chilled to 0° C., centrifuged, washed in the cold, and resuspended in distilled water. An aliquot was used for the determination of the total radioactivity of the cells, and the remainder was digested with alkaline hypochlorite. The polymer was extracted from this digest by shaking twice with chloroform, and 10 mgm. of purified polymer was added to the chloroform extract to serve as carrier. The extract was then washed with water and evaporated to dryness. The residue was redissolved in hot chloroform, and the polymer was precipitated from this solution by the addition of an acetone–ether mixture. The amount of polymer synthesized was calculated from the radioactivity of the polymer so recovered. The results (Table 4) show that a large part of the carbon assimilated from glucose, acetate and butyrate under conditions where the efficiency of assimilation is very high is incorporated in the polymer fraction.

Table 4. Oxidative Assimilation of Small Quantities of Glucose, Acetate and Butyrate, Uniformly Labelled with Carbon-14, by Starved Cells of *Pseudomonas saccharophila*

	Substrate furnished		
	Glucose-^{14}C 5 μmoles	Acetate-^{14}C 20 μmoles	Butyrate-^{14}C 10 μmoles
Substrate metabolized, μatoms of C	24·2	38·4	33·4
Substrate assimilated by cells, μatoms of C	14·4	17·5	20·8
Substrate incorporated in polymer fraction, μatoms of C	9·2	14·4	16·7

Other tracer experiments have shown that the polymer can serve as a substrate for endogenous metabolism in *Pseudomonas saccharophila* in the absence of an exogenous carbon source. It is, however, much more slowly metabolized than in *R. rubrum* and a net transfer of polymer carbon to other cell constituents has not yet been demonstrated.

We wish to acknowledge the valuable assistance of Miss Riyo Kunisawa and Mrs. Rebecca Contopoulou in the performance of the experiments. Radioactive substrates were kindly furnished by Prof. H. A. Barker. The work forms part of a programme supported by a grant from the National Institutes of Health.

A NEW SHORT-ACTING THIOBARBITURATE

By Dr. M. E. PEEL, BARBARA MACAULEY*, Dr. H. O. J. COLLIER†, Dr. J. H. HUNT, Dr. F. A. ROBINSON and Dr. E. P. TAYLOR

Research Division, Allen and Hanburys, Limited, Ware, Herts

OF the thiobarbiturates used as intravenous anæsthetics, thiopentone, introduced in 1934, has been in recent years the most widely used. Figures for 1955 show that it was employed "in over 80 per cent of all anæsthetics in Great Britain"[1].

Unfortunately, while thiopentone produces anæsthesia of brief duration, considerable time may elapse following recovery of consciousness before the mental faculties of the patient return completely to normal, which is a disadvantage in some circumstances. Indeed, Dundee[2] states that "All out-patients who are to receive thiopentone must have the hazards explained to them beforehand and an escort for the journey home must be insisted upon. Unless arrangements are made for this escort or the patient is willing to spend the night in hospital, thiopentone should not be given".

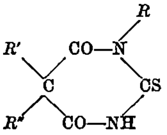
Following a suggestion made by Dr. J. G. Bourne, a search was initiated for an intravenous anæsthetic from which recovery would be more rapid than from thiopentone.

It is known[3,4] that N-alkylation of 5 : 5-disubstituted thiobarbituric acids tends to shorten the duration of action, and accordingly some 150 new N-alkyl thiobarbituric acids were synthesized.

The alkylation of 1 : 5-dialkyl thiobarbituric acids was first investigated, but this resulted in S-alkylation with the formation of the apparently unrecorded 2-alkylmercapto-1 : 5-dialkyltetrahydropyrimidine-4 : 6-diones. The required 1 : 5 : 5-trialkyl thiobarbituric acids were therefore prepared by conventional methods, for example, by the condensation of N-alkyl thioureas with either (*a*) the appropriate cyanoacetic ester (with subsequent hydrolysis) or (*b*) the appropriate malonic ester.

These compounds were examined pharmacologically by a step-wise procedure designed to screen for potency, safety and brevity. Each compound was administered intravenously to mice, and their responses were determined on the rotating drum[5]. The median effective dose (*ED*50) so found was then compared with the median lethal dose (*LD*50) to give an approximate therapeutic index. When this index permitted, the duration of action was measured at doses effective in all animals but lethal to few or none. Results of such experiments with some of these compounds are summarized in Table 1.

Table 1. POTENCY, TOXICITY AND DURATION OF SOME THIOBARBITURIC ACIDS IN MICE
Values are expressed in mgm./kgm. acid with 0·95 fiducial limits



Compound	*R'*	*R''*	*R*	*ED*50 (fiducial limits)	*LD*50 (fiducial limits)	*LD*50/*ED*50	Approximate duration at 7 × *ED*50 (sec.)
Thiopentone	1. Me–Bu^n	Et	H	5·98 (4·44–6·95)	70·25 (61·76–87·10)	12·08	3,500
Buthalitone	Bu^i	Allyl	H	17·25 (15·30–18·80)	149·9 (106·9–158·2)	8·69	20,000
B.82	Bu^i	Allyl	Me	9·57 (9·05–10·12)	81·96 (76·54–87·76)	8·56	550
B.116	Bu^i	Allyl	Pr^n	24·11 (20·09–28·92)	103·50 (96·36–111·10)	4·29	—
B.117	1. Me–Bu^n	Allyl	Bu^n	20·40 (15·42–26·99)	76·43 (61·60–94·84)	3·75$^-$	—
B.133	Bu^i	Et	Me	7·33 (6·57–7·95)	76·17 (69·76–80·98)	10·39	600
B.86	Bu^i	Et	Et	13·21 (11·59–15·07)	93·17 (86·94–99·86)	7·05$^+$	—
B.137*	Bu^i	Et	Me	7·38 (6·31–8·22)	83·60 (80·65–87·06)	11·33	550
B.135	Bu^s	Allyl	Me	6·05 (5·25–6·72)	73·38 (70·55–76·17)	12·13	450

B.139	Bu^i	Pr^n	Me	11·68 (10·22–13·32)	71·06 (64·34–78·50)	6·08	—
B.158*	Bu^s	Et	Me	6·79 (5·97–7·72)	73·86 (70·30–77·82)	10·88	1,000

* Racemic stereoisomers.

From Table 1 it will be seen that the ratio *LD*50/*ED*50 falls as the size of the alkyl group on the nitrogen atom increases (for example, buthalitone, B.82, B.116; B.133, B.86; B.135, B.80). The greater brevity of B.82 compared with buthalitone illustrates the rule that methylation of the nitrogen atom tends to shorten the duration of action.

Fig. 1 illustrates the relation of dose to duration of narcosis with those compounds in Table 1 in which the index *LD*50/*ED*50 is high. With B.82 the line relating duration of action to dose remained straight even when carried into the range where some doses were lethal. With buthalitone this line turned sharply upwards long before lethal doses were reached, and higher doses gave narcosis too prolonged to be accommodated on the scale of the graph (see Table 1). The

---

† Present address: Department of Pharmacological Research, Parke, Davis and Co., Ltd., Hounslow, Middlesex.

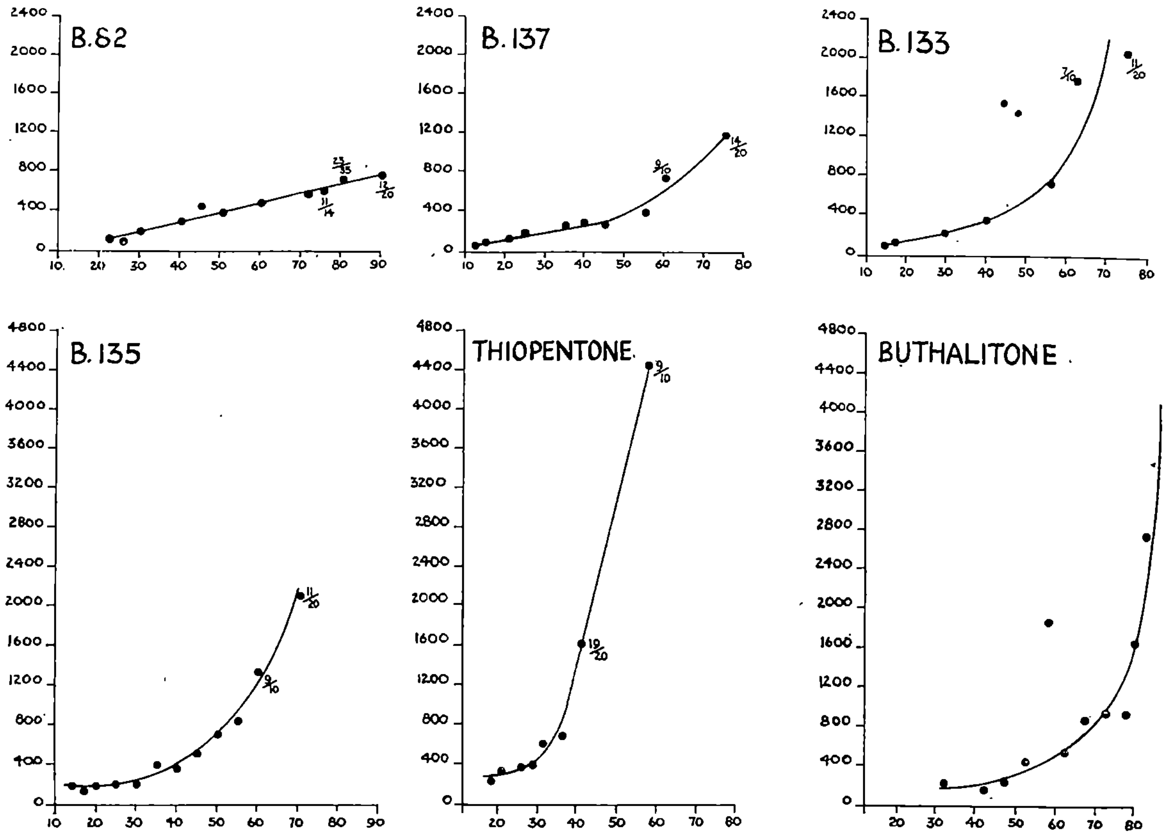

Fig. 1. Relation of dose to duration of thiobarbiturates administered intravenously to mice. All doses were effective in all mice. Where some mice died, the proportion of survivors is indicated. Ordinates, mean duration in sec.; abscissæ, intravenous dose in mgm./kgm.

curves for other compounds were intermediate in slope between those of B.82 and of buthalitone. B.158 is not included in Fig. 1, but it had a curve comparable to that of thiopentone. The flatness of the curve at high doses was taken as a favourable feature in selecting compounds for further study.

A similar procedure was adopted for selected compounds in rabbits except that loss of righting response was used instead of the rotating drum as a test of effectiveness. Some compounds were also administered intravenously to cats in order to observe the effect on blood pressure and cardiac rhythm. Compounds which possessed potency and safety comparable to thiopentone and which were considerably briefer in duration were examined by further tests, which included cumulative action and depression of respiration in rabbits, depression of ganglionic transmission in cats, local and sub-acute toxicities and duration of action after experimental liver or kidney damage in mice.

Members of the S-alkyl group had low therapeutic indices in mice and caused cardiac arrhythmias in cats. These compounds were therefore not pursued further.

The properties of three of the compounds in Table 1 (B.82, B.133 and B.137) appeared sufficiently promising in animals to warrant their preliminary investigation in man. B.82 and B.133 were soon discarded owing to the incidence of muscular tremor, sneezing or hiccough (Bourne, J. G., private communication). B.137, however, did not show these undesirable side-effects, and in a series of 71 cases receiving identical doses of either B.137 or thiopentone, no variation was observed in reactions or the time of the induction period; surgical anæsthesia was equally satisfactorily produced by either drug. Moreover, the time of recovery following administration of B.137 was approximately half that required for recovery from thiopentone (Day, D., private communication). Similar results were obtained in a smaller trial of 12 cases (Rees, L. T., private communication). Wider clinical investigations are now in progress.

The potency, toxicity and duration of B.137 in rabbits are compared with those of thiopentone in Table 2.

Table 2. Potency, Toxicity and Duration of B.137 and Thiopentone in Rabbits
Values are expressed in mgm./kgm. ± standard error

Compound	*ED*50	*LD*50	*LD*50 / *ED*50	Approximate duration at 7 × *ED*50 (sec.)
Thiopentone	2·03 ± 0·26	26·51 ± 0·42	13·06	1,200
B.137	2·12 ± 0·24	29·73 ± 0·83	14·02	700

B.137, a white crystalline solid (m.p. 96–97° C.), is the higher melting of the two possible racemic forms of 1-methyl-5-*sec*butyl-5-ethyl-thiobarbituric acid: B.158 (m.p. 56–57° C.), the other form, has been separated and also independently synthesized.

Like thiopentone, B.137 is best administered as its sodium salt, and is presented as a sterile mixture of this salt with a suitable buffer. The chemistry and pharmacology will be described in further detail elsewhere.

We thank Dr. J. G. Bourne for his valuable advice, Mr. R. T. Brittain for some experimental contributions, Miss J. Heathcote for assistance in the pharmaceutical presentation, Mr. J. J. Grimshaw for statistical analysis, Mrs. E. Nield, Miss A. Stripling and Mr. S. Ward for technical assistance, and the Directors of Allen and Hanburys, Limited, for permission to publish this work.

AMINO-ACID COMPOSITION OF THE PROTEINS OF BARLEY LEAVES IN RELATION TO THE MINERAL NUTRITION AND AGE OF PLANTS

By DR. B. P. PLESHKOV* and DR. L. FOWDEN†

It is well known that the total nitrogen content and the relative amounts of different nitrogenous fractions of plants vary with their age and conditions of mineral nutrition. Particular attention has been paid to the free amino-acid fraction; in general the content of free amino-acids in plants increased under conditions of potassium[1–3], sulphur[4,5], calcium, magnesium and boron[6], and zinc, copper, manganese and iron[7–9] deficiencies. A similar increase results when plants are supplied with abundant nitrogen[2,10] or chlorine[11]. Nitrogen and molybdenum deficiencies caused a decrease in the free amino-acid content[2,3,8,10]. The free amino-acid content of the vegetative organs generally decreases with increasing age of the plant[5,10].

The amino-acid composition of the proteins of the vegetative organs and the changes of composition caused by different environmental factors have been studied to a lesser extent. Recent results suggest that the amino-acid composition of the proteins of the active vegetative organs is approximately constant. The investigations of Fowden showed that a close similarity exists between the composition of proteins isolated from different algae[12] and that the composition of *Chlorella* proteins does not change significantly with age[13]. Yemm and Folkes[14] did not find any significant differences between the amino-acid composition of the cytoplasmic and chloroplastic proteins of barley leaves, while Bryant and Fowden[15] detected only small differences in the amino-acid composition of the proteins extracted from daffodil leaves of different ages. This constancy of composition is not absolute, and results have been obtained indicating that the contents of individual amino-acids in the proteins isolated from sugar beet of different ages vary considerably[16]. No observations appear to exist relating plant protein composition with the conditions of mineral nutrition under which the plant developed.

The aim of the present work was to study the content of the free amino-acids and the amino-acid composition of the proteins of barley leaves of different ages grown under different nutrient conditions in respect to nitrogen, phosphorus and potassium. The barley (variety *B*-2118) was grown in sand culture in Richards's nutrient solution[17] either complete or at one-tenth dilutions in respect of nitrogen, phosphorus and potassium separately. Samples were collected 24 and 48 days after germination of the plants; the whole of the aerial portion of the plants was taken for analysis. Leaf proteins were extracted and hydrolysed by the method described earlier[15]. Free amino-acids were extracted with 80 per cent ethanol from individual plant samples, and each acid was determined quantitatively by paper chromatography[15]. Tryptophan was determined by the method of Spies and Chambers[18] (procedure K) and proline by Chinard's method[19].

The total nitrogen, protein nitrogen and amino-acid concentrations of the plants are given in Table 1. Total and protein nitrogen decreased with increasing age of plant. Considerable differences were also detected between plants receiving different treatments. Nitrogen deficiency caused a striking decrease in total and protein nitrogen; in potassium-deficient plants the total nitrogen concentration was practically unchanged, but protein nitrogen decreased markedly, especially in plants 48 days old; phosphorus deficiency also reduced the total and protein nitrogen of the plants.

In plants grown under normal nutrient conditions the total free amino-acid concentration decreased noticeably with age. All amino-acid concentrations were reduced in approximately equal proportions except those of aspartic acid and alanine, which were decreased more markedly than the rest. A slight increase in the concentration of γ-amino-butyric acid was observed. After only 24 days, nitrogen deficiency had caused a large decrease, relative to the control plants, in the concentrations of all amino-acids except tyrosine and proline. The tyrosine-level remained approximately unchanged while proline was increased three-fold. In 48-day-old nitrogen-deficient plants, total free amino-acids decreased to a still lower level. The further reduction affected mainly aspartic and glutamic acids, serine, glutamine, asparagine and proline. Only the pipecolic acid concentration

remained unchanged when compared with control plants. Phosphorus- and potassium-deficient plants contained approximately the same total amounts of free amino-acids as control plants at the 24-day stage; at 48 days these totals remained unaltered for the deficient plants, although the level of free amino-acids in control plants had decreased. Variations in the amounts of certain individual amino-acids relative to the controls served to characterize the deficient plants. Phosphorus deficiency was associated with a decrease in the concentration of glutamic acid and a corresponding increase in glutamine, the concentration of which was five times that of normal plants at the 48-day stage. Unusually high pipecolic acid concentrations were also associated with phosphorus deficiency. Potassium deficiency was characterized mainly by a slight decrease of the concentrations of glutamic and aspartic acids relative to control plants and a marked increase in asparagine concentrations. At 48 days, one-third of the total nitrogen of the free amino-acids was in the form of this amide.

The amino-acid compositions of the protein preparations from the corresponding plants are given in Table 2. Although marked differences occurred in the total and protein nitrogen-levels of the plant tissues of different age and nutritional status, the amino-acid composition of their proteins showed distinct similarity; the values obtained for many amino-acids do not differ significantly for the various treatments if allowance is made for an experimental error of ± 5–7 per cent of the reported values. There is a trend in the proteins of older plants towards decreasing amide- and arginine-levels and slightly increased lysine contents. Nitrogen deficiency produced a definite decrease in the amide content at 24 days, and in histidine at 48 days. Smaller changes in the contents of threonine, alanine, methionine, arginine, proline and tryptophan also occurred as the nutrient conditions were varied.

Actively growing vegetative plant organs contain a large number of different enzymic proteins having different amino-acid compositions; at various stages of plant development, and under various environmental and nutritional conditions, the relative amounts of these proteins may vary widely. However, analyses of 'bulk' proteins show only their mean amino-acid composition, and real differences in concentrations of individual proteins can become masked when analyses are portrayed in terms of 'bulk' protein composition. The similarity of the amino-acid compositions determined for the proteins of plants grown under different nutrient regimes can then be still compatible with an altered balance in the complement of individual proteins.

Analysis of the barley proteins consistently revealed a new unknown amino-acid in addition to the amino-acids characteristic of proteins. The R_F of this amino-acid in butanol/acetic acid/water solvent[20] was approximately half that of cysteic acid, and so it was the slowest-moving component of the protein hydrolysate. It was only possible to detect this substance after chromatograms had been developed for at least 6 days. A few milligrams of partially purified material has been isolated, and by means of electrophoresis it has been shown to have a slightly acidic character. The values given in Table 2 for the content of this amino-acid in the protein preparations are calculated assuming a molecular weight of 75; that is, the same as glycine. The amounts of the amino-acid contained in the proteins definitely increased with the age of the plant. Isolation and identification of this amino-acid will be a problem for future investigation.

One of us (B. P.) wishes to thank Dr. G. W. Cooke for his advice and help during these investigations.

RADIOBIOLOGY

Uptake of Strontium by Pasture Plants and its Possible Significance in Relation to the Fall-out of Strontium-90

The recognition of the importance of the chain, plant–animal–man[1], in the uptake of strontium-90 by humans as a result of the fall-out of fission products made it desirable to see if species differences existed in forage plants, such that some might take up less strontium from the soil than others. This knowledge might then be used to reduce the radiostrontium content of milk, or to choose species for the reclaiming of contaminated land.

Sixteen species and strains of forage plants were grown in 1-gallon stone crocks on three different soils, similar in texture and *p*H but varying in strontium and calcium content (Table 1). Neither radioactive nor stable strontium was added to the soil, because of the difficulties of mixing and because the very small amounts of native strontium should give a better picture of the uptake of minute amounts of strontium by plants. Harvesting was carried out at eight weeks, when the plants reached the stage of incipient flowering or had reached maximum vegetative growth.

Table 1. Strontium and Calcium Content and *p*H of the Soils Used in the Experiment

Soil	Calcium (μeq./100 gm.)	Strontium (μeq./100 gm.)	Calcium/ strontium ratio	*p*H
Nord fine sandy loam	17,260	52·8	342	7·4
Yolo fine sandy loam	7,500	23·8	315	6·9
Sacramento fine sandy loam	4,460	17·6	253	7·0

Strontium was determined by a General Electric model *XRD-5* X-ray spectrograph, and we are greatly indebted to Dr. L. D. Whittig for instructing us in the use of this instrument. The general procedure of Brandt and Lazar[2] was modified[3] to enable a working curve to be prepared without the use of chemically analysed samples. The soils were extracted[4] with ammonium acetate–ammonia at *p*H 9·0.

The results (Table 2) indicate five significant features. (1) Every legume species takes up more strontium than any grass—three to six times as much in many cases. (2) Within either the grasses or the legumes the variation in strontium content is not marked. (3) The amount of strontium taken up is directly related to the amount of calcium taken up. (4) There is no major discrimination between strontium and calcium by either grasses or legumes. (5) Neither the grasses nor the legumes can be ranked in the same order of strontium content for every soil, but *Bromus inermis* and *Trifolium subterraneum* are consistently highest in their respective classes. Of the legumes, *Lotus corniculatus* has the least strontium, while *Phleum pratense*, *Dactylis glomerata* and *Phalaris tuberosa* are the lowest-ranking grasses.

The results indicate that animals grazing mixed legume-grass herbage, where the legume amounts to a significant proportion of the forage, will ingest much more strontium-90 than animals grazing all-grass pastures on equally contaminated soils. It is apparent that if the strontium-90 level in milk should ever

rise to a level which, maintained over a period of time, might give cause for concern, it would be desirable to restrict dairy cows to an all-grass diet. On current evidence this situation is unlikely to occur if the present level of atomic weapon testing is maintained, but in the future it might prove desirable to take this measure to reduce the strontium-90 level in milk, particularly that consumed by children. Such measures might first become necessary in regions of high rainfall, or where other local factors predispose a higher than average radiostrontium content of milk. Milk radiostrontium contents as high as 32 s.u. have been reported[5].

Where land that is relatively heavily contaminated with strontium-90 must be actively farmed, then bare fallow should be sown with an appropriate grass, no clover being included in the mixture. Established pastures should be heavily fertilized with nitrogen to encourage the growth of grass at the expense of clover.

Plants and Fall-out

It has been suggested that the gist of certain unpublished observations on the condition of certain plants in the area of the Marshall Islands affected by fall-out from the 1954 Bikini hydrogen bomb test should be made public in order to stimulate further investigation on the subject of cumulative effects of low-level radioactivity in plants. These observations have hitherto remained unpublished because of their preliminary and inconclusive nature.

In earlier fall-out surveys of 1954 and 1955, made by non-botanical observers, in the atolls of Rongelap, Ailinginae, Rongerik and Utirik no visible effects on plants were observed, although accumulation of radioactive materials in plant tissues was demonstrated. In the 1956 re-survey, under the auspices of the U.S. Naval Radiological Defense Laboratory, only casual observations were made on the condition of the plants, attention being concentrated on collection of material for analysis. Eight coral islet stations were examined which had been affected by different intensities of fall-out.

Later study of notes made on the vegetation on these islets showed abnormal or pathological conditions in certain plant species, increasing from islet to islet in the same order as the increase in fall-out intensity. Since the observations were not made systematically, nor with the possibility of visible pathological effects in mind, only the roughest of correlations is possible. Even so, the differences were striking enough to merit further attention.

On Gegen Islet, Rongelap Atoll, the station with the greatest fall-out exposure, of a total flora of 15 species, 13 showed conspicuous pathological or abnormal symptoms, ranging from plants dead or almost so to chlorosis, dead terminal twigs and mistletoe-like abnormal growths.

On Kabelle Islet, Rongelap Atoll, next most heavily exposed, 3 species showed some damage.

On all other stations at most one or two species showed effects, but on Eniwetak Islet, Rongerik Atoll, though only two species were involved, the symptoms, defoliation and die-back of twigs, were so conspicuous as to alter the appearance of the vegetation, causing a general grey colour in place of the normal green.

On Likiep Islet, Likiep Atoll, which had scarcely any measurable fall-out, no abnormal appearances of any sort were noticed.

The plants most widely affected were: *Suriana maritima* L., which was completely dead on Kabelle Islet and partially dead on other islets where it was observed; *Cordia subcordata* Lam., which on Gegen Islet was dead or almost so, and on Eniwetak Islet, where it is the most important tree in the vegetation, had the tips of almost all its twigs dead for 10–15 cm.; and *Pisonia grandis* R. Br., which was more or less leafless on the more affected islets and bore, on Gegen Islet, curious mistletoe- or witches-broom-like leafy branches of a dark green colour which have not been noted elsewhere on this species. The defoliation of the last species is not necessarily abnormal, as it happens during severe drought periods. Its association with the stations where fall-out was relatively heavy and without other evidence of drought makes it of interest.

In all, 43 species are known from Rongelap, Rongerik and Ailinginae, the three atolls heavily affected by fall-out. Only about half these plants grow on the four islets where the heaviest fall-out was recorded. Of these, 16 species were noted to show some abnormality. Two species of universal occurrence and great abundance, *Scaevola sericea* Vahl and *Tournefortia argentea* L. f., showed no abnormal appearance whatever.

It will be noted that the total flora of these islands is very small and made up of strand species, tolerant of high salt concentration and exposure to drying winds.

I am very familiar with the flora and vegetation of coral atolls, generally, and with the Marshall Islands, especially, so that the observations are of more significance than if I had less background.

It is not suggested that these observations are positive indication of cumulative effect of fall-out. There may be other unsuspected causes. However, the correlation between intensity of observed symptoms and intensity of recorded fall-out is at least suggestive, and would seem to justify further investigation. The extreme diversity in the reactions of different species growing under the same conditions to whatever caused these effects is of great interest. It suggests the advisability of using a wide variety of plants in any set of experiments designed to investigate the effects of radioactivity, as well as those of other environmental factors. It becomes harder and harder to generalize on the influence of any factor on plants.

Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils

THE long-term effects of low-level chronic irradiation on living organisms have attracted increasing interest in connexion with the observed contamination from man-made radioactive sources over large areas of the Earth's surface. No experimental evidence exists that definite biological changes are induced in a large population under very low continuous exposure.

The assessment of sensitivity during the process of germination may provide a satisfactory approach, as seeds are available from plants of the same species that have—or have not—grown for ages in a radioactive environment, thus being continuously irradiated. We used seeds of *Andropogon filifolius* (Nees) Steud, a perennial grass[1], collected by one of us on neighbouring uraniferous (Kasompi) and non-uraniferous, but otherwise similarly mineralized, soils (Dikuluwe) in Katanga (Belgian Congo). The dose received by the sexual or somatic cells of these plants is impossible to calculate, mainly because the radioactivity of the superficial layers of the soil is extremely variable—from 10 to 50 times background.

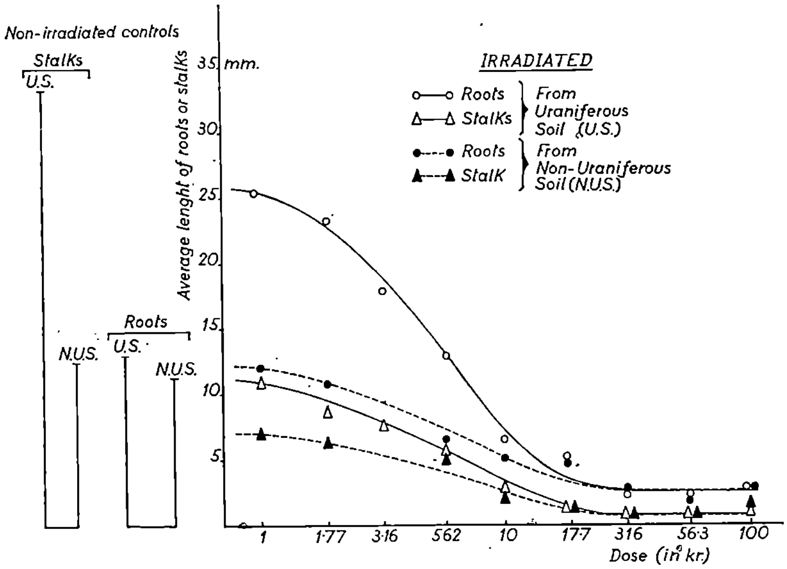

Fig. 1

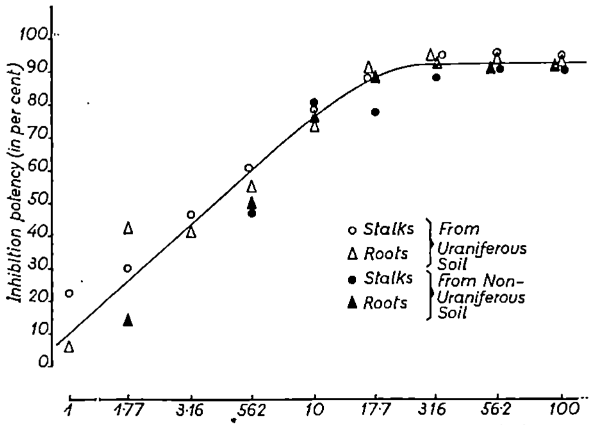

Fig. 2

Table 1

Dose (r)	Germination (per cent)	
	Uraniferous soil	Non-uraniferous soil
0	30·0	18·0
1,000	26·7	18·0
1,770	24·0	22·0
3,160	30·7	22·0
5,620	28·0	24·0
10,000	24·6	11·5
17,700	24·7	14·0
81,600	21·9	13·3
56,200	19·3	11·1
100,000	19·9	17·3

Groups of seeds (150) soaked for 12 hr. from both soils were irradiated simultaneously on moist filter paper at different doses with a Siemens 'Stabilivolt' (200 kV.; 20 m.amp.; no filter; source-target distance: 30 cm.; rate, 700 r./min.). All seeds were grown in a greenhouse on moist filter paper. Three criteria were investigated: germination, and maximal lengths of stalks and roots[2] at the time of death of the plantlets. The percentage of 'normal' germination and length of stalk and roots were estimated from un-irradiated control groups (± 1·800 seeds). The results are shown in Table 1 and Fig. 1.

Seeds originating from uraniferous soil exhibit a higher percentage of germination, and plantlets develop stalks and roots of greater average length. Germination is not significantly inhibited by radiation in the range used. At any dose-level, the average length of roots and stalk is greater in plants from uraniferous soil. The potency of radiation in inhibiting growth of roots and stalks may be expressed as the percentage of shortening of initial length per roentgen. It decreased exponentially with dose and reached a plateau at the 20,000 *r.* dose-level; no significant difference was evident between either series (Fig. 2). However, the observed differences between percentages of germination and lengths of organs of plants from uraniferous soils and those from non-uraniferous soils lead to the conclusion that the two populations are different. The chronically irradiated population possesses higher vitality. Whether selection or adaptation or both are responsible is an open matter. In any event, enhancement of biological potentialities rather than degeneration has apparently resulted from long-continued low-level irradiation of *Andropogon filifolius.* This experiment is now being repeated with another species of *Andropogon.*

We thank the officers of the Union Minière du Haut Katanga and especially the geologists for their kind collaboration in collecting specimens.

Modification of the Oxygen Effect when Bacteria are given Large Pulses of Radiation

Many biological materials, including bacteria, have been shown to be more readily damaged when oxygen is available to the cell at the time of irradiation than when it is absent[1,2]. *Serratia marcescens* shows this enhanced sensitivity to radiation—the so-called 'oxygen effect'—almost to the full extent when a suspension of them is saturated with a gas mixture containing only 1 per cent oxygen and 99 per cent nitrogen, provided the radiation is given at normal dose-rates of about 1,000 rads/min. Typical inactivation curves for this organism using 1·5 MV. X-radiation from a pulsed linear accelerator are given in Fig. 1. Using the intense electron beam from the same linear accelerator, however, a dose of some 10–20 kilorads can be delivered in 2 microsec. The results quoted below indicate that when such large single pulses are used, the same bacteria saturated with the same oxygen–nitrogen mixture show the lower sensitivity corresponding to anaerobic irradiation. This is thought to be due to the fact that the first few kilorads of the electron pulse remove dissolved oxygen from the interior of the bacterium by radiation-induced reactions. During the remainder of the pulse the bacterium will thus be receiving radiation under essentially anaerobic conditions. Even though dissolved molecular oxygen may not be entirely removed by the radiation from the extracellular liquid, this cannot penetrate the cell by diffusion in the 2 microsec. that the pulse lasts.

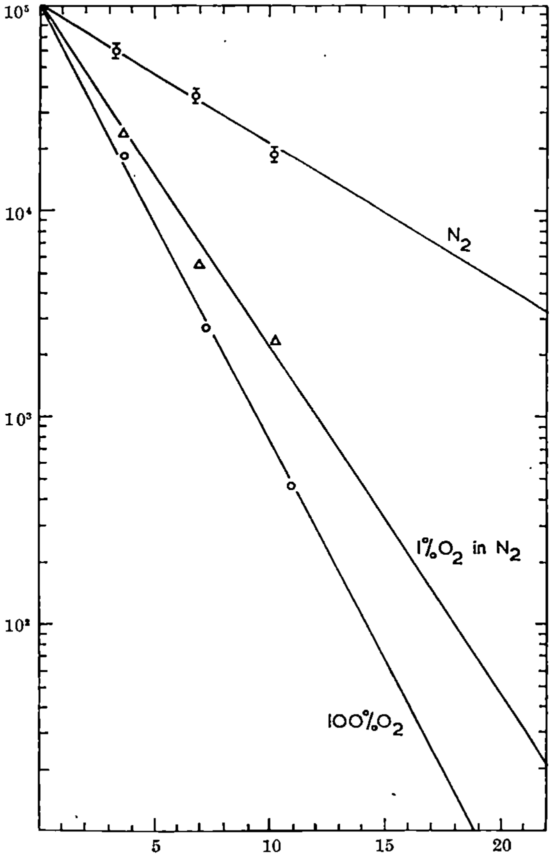

Fig. 1. Number of *Serratia marcescens* surviving from 10^5 bacteria after 1·5 MV. X-radiation while equilibrated with nitrogen, oxygen and a mixture of 1 per cent in nitrogen. Dose-rate = 600 rads/min.

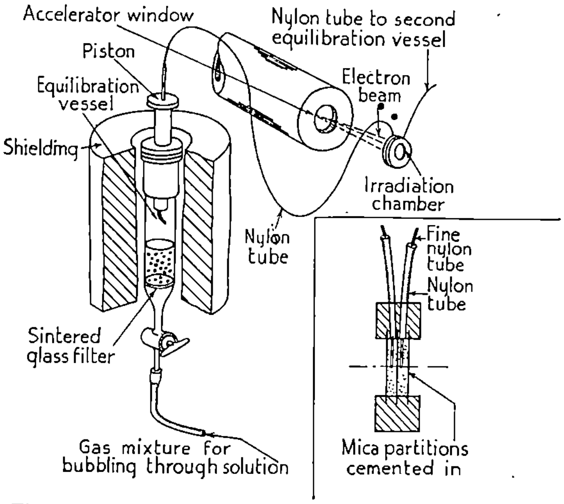

Fig. 2. Apparatus for equilibrating the bacterial suspensions and filling the irradiation chamber. Inset, an enlarged view of the irradiation chamber showing the two compartments

The experimental apparatus is shown in Fig. 2. In order to obtain an adequate dose, the irradiation chamber had to be placed about 10 cm. from the exit window of the accelerator, and to obtain a tolerably uniform dose distribution its size had to be restricted to 0·2 ml. The irradiation chamber had two compartments, one behind the other, separated only by a thin mica foil so that every electron pulse passed through both. One was generally filled with a suspension of bacteria saturated with nitrogen and the other with a suspension of bacteria saturated with the gas mixture under test.

The chambers were too small to permit internal gas bubbling, and each bacterial suspension was therefore equilibrated with the gas under test in a separate glass funnel closed by an air-tight plunger. Gas escaped from this through a fine nylon tube which terminated inside the irradiation chamber. After an adequate period of equilibration, the bacterial suspension was transferred to the irradiation chamber by depressing the plunger until the nylon tube dipped below the surface of the liquid, and the suspension was forced along into the cell. Irradiation was completed within a minute of transferring the bacteria, and during this time the removal of oxygen by respiration was found to be negligible at the bacterial titre used. Control samples were taken from both equilibration vessels immediately after each pulse of electrons. The equilibration vessels were heavily shielded during irradiation.

In a preliminary control experiment, when both compartments were filled with bacteria saturated with oxygen-free nitrogen, the ratio of the doses received in the separate compartments could be measured biologically by the survival of the bacteria, as indicated by visible colony counts on nutrient agar plates. The same ratio could be measured physically by the ultra-violet absorption induced in small 'Perspex' monitors[3] placed in the position of the cell compartments. The two estimates of the dose ratio were:

$$\frac{\text{Dose in back compartment}}{\text{Dose in front compartment}} = 1{\cdot}36 \text{ by bacterial survival}$$

$$= 1{\cdot}22 \text{ by ultra-violet absorption in 'Perspex'}$$

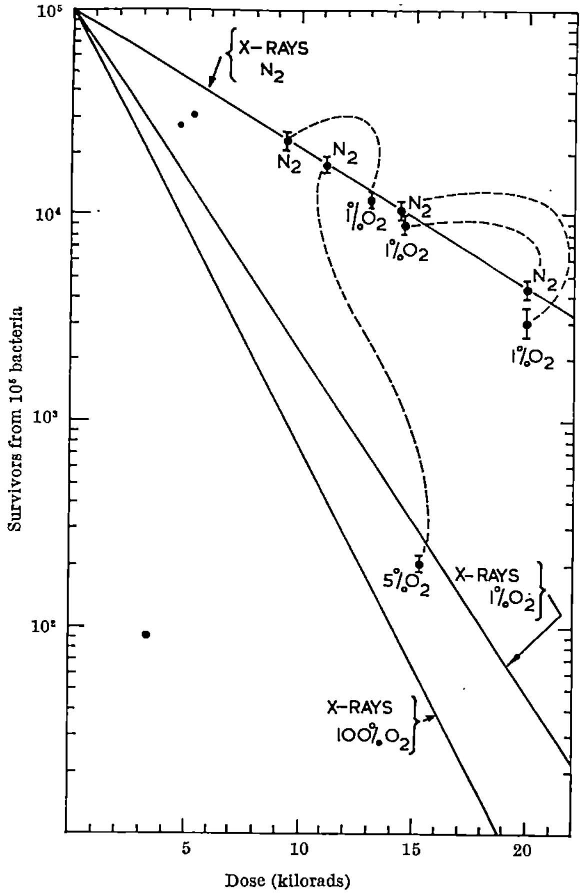

Fig. 3. The effect of single electron pulses on *Serratia marcescens*. The straight lines are X-ray survival curves taken from Fig. 1. The pairs of points joined by dotted lines are the survivors from the two compartments of the double cell, after a single pulse of electrons

The final conclusions were made largely independent of any differences in dose delivered to the two cells by doing each experiment twice—once with the reference suspension of nitrogenated bacteria in the front compartment and once with it in the back compartment. In plotting the results the biological estimate of the ratio, that is, 1·36, has been used as this was considered the more direct measurement; but the conclusions would be quite unaffected if the other value 1·22 had been used.

Fig. 3 is a plot of the observations made with pulsed doses in relation to the straight lines for lower dose-rates taken from Fig. 1. For each radiation the survival in the anaerobic compartment has been taken as a measure of the dose and is therefore plotted on the nitrogen line. The point derived from the other compartment is linked with the corresponding nitrogen point by a dotted line. Bacteria which had been equilibrated with 1 per cent oxygen in nitrogen showed approximately the anaerobic sensitivity, whereas bacteria equilibrated with 5 per cent oxygen in nitrogen showed nearly the full oxygen effect. In the latter case, there was evidently too much dissolved oxygen within the bacillus for it to be removed by the early part of the electron pulse and so most, or perhaps all, of the dose was delivered in the presence of sufficient dissolved oxygen.

An alternative explanation of the effects described above, based on radiation-chemical interaction between clusters of ions formed in adjacent electron-tracks in the single pulse, is unlikely to be correct. In order to approach the concentration of ions found in the core of an α-particle track an instantaneous dose of some 10^9 rads would be required.

Experiments with the pulsed irradiation are continuing to determine more exactly the shape of the survival curves for different initial concentrations of dissolved oxygen.

We are greatly indebted to Dr. L. H. Gray, who suggested this experiment, and has throughout given his advice and encouragement.

Action of Ultra-violet Light on Skin: Effect of the Histamine Liberator 48/80 and Methotrimeprazine

Rottier and Mullink[1] irradiated human skin with ultra-violet light at a place where the horny layer had been removed by repeatedly applying adhesive tape. The erythemal reaction practically disappeared at wave-lengths 250–260 mμ, but increased at 300 mμ. They therefore suggested that photolysable substances from the stratum corneum were responsible for the erythemal reaction caused by ultra-violet light of wave-length 250–260 mμ. The problem concerning the mediator substance in ultra-violet erythema still seems to be unsolved. Lewis and Zotterman's[2] suggestion that it should be histamine has not been confirmed[3]. Recently, much interest has been focused on 5-hydroxytryptamine as a possible mediator in the production of œdema.

It is therefore of interest to obtain information about the role taken by histamine and 5-hydroxytryptamine in the production of ultra-violet light erythema at the two wave-lengths mentioned above, both in intact skin and in skin where the superficial layer has been removed by tape. This has been done by treating the animals subjected to irradiation with 48/80, which liberates both histamine and 5-hydroxytryptamine, and with methotrimeprazine (7044 *RP*), an inhibitor of 5-hydroxytryptamine[4].

Experiments were performed on albino male rats (100–120 gm.) where the stratum corneum had been removed from one side of the shaved back by applying adhesive tape. For irradiation, the rats were fastened to boards and covered with black rubber sheets with three 16-mm. holes on each side of the spine. Radiation of wave-length 280–330 mμ was obtained from a water-cooled, high-pressure mercury arc (Philips *SP* 500 W.) provided with filter (2 mm. Jena *WG* 7 + 10 mm. $NiSO_4.6H_2O$, 600 gm./l.). For the wave-length 253·7 mμ, a low-pressure mercury arc was used. The doses, measured by chemical actinometry[5], varied from about 2×10^{16} to 5×10^{18} $h\nu$/cm.². The degree of tissue damage was estimated from the leakage of intravenously injected Evans blue into the irradiated areas[5,6].

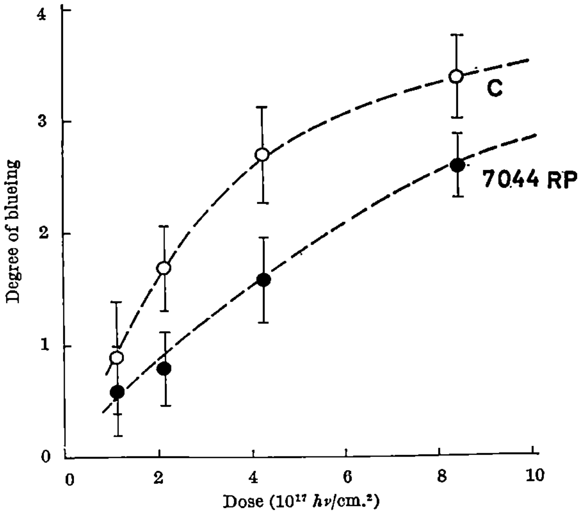

Fig. 1. Degree of blueing (tissue injury) versus dose for rats treated with 7044 *RP* after irradiation (●) and for control animals (○). The vertical lines indicate the standard deviation from the mean

Of the 60 animals used, one third were pretreated intraperitoneally with compound 48/80 in increasing doses from 100 to 700γ for 7 days previous to irradiation. Another third were injected intravenously immediately after irradiation with 0·5 mgm. 7044 *RP*. The remainder were used as controls, and irradiated simultaneously with the other animals.

In all cases, and for both wave-lengths, removal of the corneum caused increased erythemal reactions at both 253·7 and 280–330 mμ. Thus for rats, the results at the wave-length 253·7 mμ are not in accordance with those found by Rottier and Mullink[1] for humans. To exclude the possibility that the difference is due to the different species used, experiments were also performed on rabbits and humans; in both cases removal of the corneum caused an increased reaction at the wave-length 253·7 mμ.

No observable change in the degree of blueing could be observed by depleting the rat-skin of its content of histamine and 5-hydroxytryptamine by use of compound 48/80.

On the other hand, the interesting observation was made that the ultra-violet light reaction in rats at 280–330 mμ could be decreased by injection of a 5-hydroxytryptamine inhibitor immediately after irradiation. This is evident from Fig. 1. These results, together with the observation[3] that a histamine inhibitor has no effect, indicate that the mediator substance in the ultra-violet reaction is not histamine, but it may be 5-hydroxytryptamine.

CYTOLOGY and GENETICS

Colour-blindness in Klinefelter's Syndrome

Males with testicular hypoplasia (Klinefelter's syndrome) are of two cytological types. A minority has sex-chromatin-negative nuclei as have normal males, whereas the majority has sex-chromatin-positive nuclei as have normal females. The demonstration of the male-determining property of the mammalian *Y*-chromosome, proved for man[1] and mouse[2], had led to a clarification of the chromosomal status of sex-chromatin-positive Klinefelter individuals. They are *XXY*[1,2].

It is well known that the frequency of females homozygous for recessive genes which are located in the *X*-chromosome is much lower than of hemizygous affected males. Thus, *X*-linked red-green colour-blindness occurs among males of European ancestry in the order of 8 per cent, whereas in females it is only about 0·5 per cent. It has been thought that a genetic correlate of the presence of two *X*-chromosomes in sex-chromatin-positive Klinefelter individuals would be a very low frequency of colour-blindness, equivalent to that in females. This expectation seemed to be borne out by studies of Polani, Bishop, Lennox, Ferguson-Smith, Stewart and Prader[3]. They tested 55 sex-chromatin-positive Klinefelter patients for their colour vision and found that none was affected. Additional tests have brought the total number to 72, all with normal colour vision (Polani, R. E., personal communication). Different results, however, were reported by Nowakowski, Lenz and Parada[4]. Among 34 sex-chromatin-positive Klinefelter individuals they detected three affected persons, two of whom were deuteranomalous and one protanopic. It will be shown that the findings of the two groups of investigators are compatible with each other and that they may provide new insight into the behaviour and constitution of human chromosomes.

One of the deuteranomalous men had a deuteranomalous mother and a father with normal colour vision. Assuming *XXY* constitution of the propositus, he would be expected to be deuteranomalous if he originated from a non-disjunctional egg carrying two maternal *X*-chromosomes fertilized by a sperm carrying a *Y*-chromosome. The other deuteranomalous and the protanopic propositus both had normal fathers, and mothers who, on independent evidence, were heterozygous for an allele for defective colour vision. How can the defective colour vision of the presumably *XXY* propositi be explained? There is a possibility, of unknown strength, that they are manifesting heterozygotes[5]. But in *Drosophila* and other organisms the phenomenon of homozygous recessive offspring from heterozygous mothers mated to hemi- or homo-zygous dominant males is well known. It occurs in consequence of crossing-over and non-disjunction. If the chromosomes of the mother carry the alleles *A* and *a*, then at meiosis four chromatids, two carrying *A* and two *a*, will be present. If no crossing-over occurs between the kinetochore and the locus of *A*, non-disjunction at the first meiotic division will produce an *Aa* egg; but if within the region designated, certain types of cross-overs occur, an 'equational' non-disjunctional egg of the type *AA* or *aa* can be formed. This apparently had occurred in the eggs which gave rise to the two presumably homozygous Klinefelter individuals with defective colour vision from heterozygous mothers.

The frequency of homozygosis due to crossing-over and non-disjunction is a function of the distance between the kinetochore and the locus concerned. With a map distance between these two so great as to result in free recombination, the maximum of 16·7 per cent of recessive homozygosis is obtained (leaving out minor complications). In other words, as the result of non-disjunction of the *X*-chromosomes in heterozygous females a maximum of about one-sixth of the *XXY* sons could be homozygous recessives. Since the frequency of women heterozygous for one or the other of the alleles for *X*-linked colour-blindness is about 15 per cent, maximally one-sixth of their Klinefelter sons from non-disjunction in the mothers, or maximally 2·5 per cent of all Klinefelters of this origin, could be colour-blind. In addition, approximately 0·5 per cent of Klinefelters would be colour-blind coming from homozygous affected mothers. A further source of colour-blind Klinefelter sons could be non-disjunction of the *X*- and *Y*-chromosomes in colour-blind men married to heterozygous or homozygous affected women. Approximately 0·5 per cent of Klinefelter individuals would be colour-blind due to this mechanism.

Depending on the relative proportion of individuals who owe their Klinefelter status to non-disjunction in the mother as compared to the father, the frequency of colour-blindness among them would vary between a maximum of 2·5 + 0·5 = 3 per cent and 0·5 per cent. The maximum expectation is statistically compatible with the observations of both groups of investigators, namely, 0 affected to 72 not affected, and 3 affected to 31 not affected. Combining the data results in 3 affected out of 106 individuals, or 2·8 per cent. The statistical uncertainty of this value is, of course, great.

An alternative hypothesis to the one proposed here would be that in man equational exceptions originate without crossing-over as the result of non-disjunction at the second meiotic division. If this were the only source of colour-blind Klinefelter males, they would constitute 7·5 per cent (from heterozygous mothers) plus 0·5 per cent (from homozygous mothers) of all propositi.

All three colour-blind individuals originated after non-disjunction in their mothers. Their frequency of 2·8 per cent suggests that most Klinefelter males with positive sex chromatin come from this source. Assuming that the first hypothesis proposed is correct, it suggests that the frequency of crossing-over among non-disjunctional eggs, leading to equational exceptions, is high. Furthermore, the high frequency of equational exceptions suggests that the locus for colour-blindness lies at a considerable distance from the kinetochore of the *X*-chromosome.

Two Types of Ribonucleoprotein in the Nucleolus of Mammalian Cells

NUCLEOLAR differentiation has been recognized since the time of Gustav Valentin. Agassiz[1] referred to a body within the nucleolus of the turtle egg as the "Valentinian vesicle". Montgomery[2] and Heidenhain[3] called this structure the nucleolinus. Recently, it has been suggested that the appearance of vesicular or solid nucleolini is due to the presence of a reticulum or thread called the nucleolonema[4]. None of the procedures that reveal nucleolonemata[4-6] has any cytochemical significance. Serra[7] suggested that the intranucleolar differentiation revealed by empirical procedures may be the result of physical rather than chemical inhomogeneity within the nucleolus. Chemical differences have, however, been found in the nucleoli of plant cells. Chayen *et al.*[8] demonstrated one or more inner zones of protein material and an outer zone that probably contained ribonucleoprotein. Further evidence of cytochemical differentiation in the nucleolus has been provided by a new stain for nucleoproteins[9].

Normal mouse and rat liver and pancreas, rat sympathetic ganglion, the Ehrlich and Krebs 2 ascites tumours, sarcoma 180 and a human epidermoid carcinoma were prepared by the toluidine blue–molybdate method to produce stage 1 of staining[9]. By this means, ribonucleoprotein of the parachromatin (nuclear sap) was coloured purple and that of the greater part of the nucleolus was stained green[9]. The nucleoli of many neurones, the parenchymal cells of liver and pancreas and neoplastic cells also contained minute unstained vacuoles and a variable amount of metachromatic ribonucleoprotein. The latter was most prominent in transplantable tumours, and especially in the Ehrlich tumour, where it was present in the nucleoli of every interphase cell in the form of minute granules, larger hollow spheres or clusters of hollow spheres (Fig. 1). Under the phase microscope numerous vacuoles were observed in the nucleoli of living cells (Fig. 2). Comparison of the nucleolus in the living cell with that in the stained preparations revealed that the metachromatic ribonucleoprotein was present in or around some, but not all, of the vacuoles (Figs. 1 and 2). This

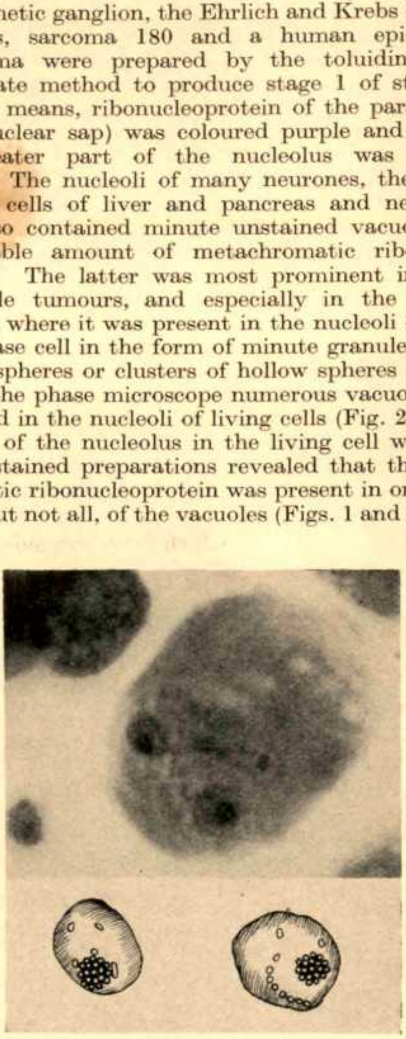

Fig. 1. Ehrlich ascites tumour cell stained by the toluidine blue–molybdate method (stage 1). Several minute vacuoles are visible in the green-staining outer zones of two prominent nucleoli. A cluster of metachromatic vesicles gives the appearance of a slightly eccentric internal body. (×1,400)

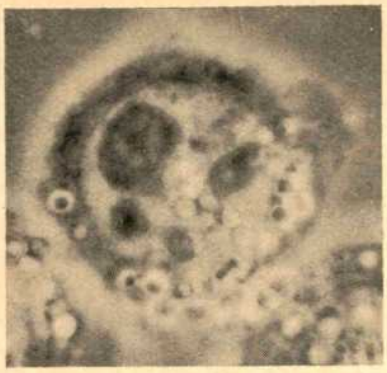

Fig. 2. Phase microscope photograph of an Ehrlich ascites tumour cell. A ring of vacuoles surrounds a dark structure in the nucleolus, in the centre of which a lighter vacuole is present. The central structure stains metachromatically by the toluidine blue–molybdate method. (× 1,400)

nucleolar ribonucleoprotein was coloured in exactly the same way as the nuclear parachromatin in all stages of staining by the toluidine blue–molybdate method and did not stain after pretreatment with ribonuclease or hot trichloracetic acid[7]; it may therefore be called the nucleolar parachromatin. In the Ehrlich ascites tumour the nucleolus often persisted throughout mitosis but was not incorporated into the daughter nucleus. In early prophase the nucleolar parachromatin was frequently at the rim of the nucleolus; during later prophase it was no longer detectable, whereas the vacuolated green-staining nucleolus was clearly visible in metaphase, anaphase and telophase. The nucleolar parachromatin was probably extruded from the nucleolus during prophase to contribute to the accumulation of granular parachromatin that took place at this time[9]. In the daughter nucleus the earliest sign of re-formation of the nucleolus was a metachromatic body which later acquired an outer coating of amorphous or vacuolated green-staining ribonucleoprotein.

The exact relationship of the two types of ribonucleoprotein in the nucleolus to the nucleolonemata and the nucleolini is not clear. In electron micrographs the nucleolonema was virtually absent in the Ehrlich tumour[6], in which the nucleolar parachromatin was most prominent. The absence of thread-like structures in the Ehrlich tumour was confirmed in electron micrographs kindly prepared by Mrs. Darlene Brindley in this laboratory. Similarly, the nucleolar parachromatin was least prominent in liver cells, where, according to Bernhard *et al.*[6], the nucleolus consists almost entirely of filaments. Although darker zones, resembling the nucleolar parachromatin, could be demonstrated around nucleolar vacuoles in rat sympathetic ganglion cells by Sotelo's method[4], the same technique did not reveal any internal structure, other than vacuoles, in the nucleoli of the Ehrlich tumour. The site and amount of nucleolar parachromatin is therefore unrelated to the ability of nucleoli to reduce iron or silver salts[4] or osmium tetroxide[5,6] to produce thread-like formations or nucleolonemata. Solid and hollow structures, resembling the nucleolini of the classical cytologists, were, however, demonstrable in Ehrlich cells stained with iron hæmatoxylin. Thus, the physico-chemical differences in ribonucleoprotein that determine differential staining by the toluidine blue–molybdate technique may also be responsible for differences in affinity for hæmatoxylin.

We wish to thank Mr. Roscoe H. Liles for valuable technical assistance and Mr. Walter C. Ashe for the drawing.

Size Relationship of Oocytes and their Nuclei in Two Species of Ascidians

NUCLEAR intervention in cytoplasmic growth and differentiation has formed the subject of many studies during recent years. One significant result from these studies is the recognition of the major part played by the nucleolus in the developing egg[1-3]. A recent review by Vincent[4] has surveyed the problem.

The determination of size of the nucleus and nucleolus in different stages of growth of the oocyte is important in such a study. Very little work on volume relationships of the different cell structures during growth has been done, and, so far as I am aware, no information is available regarding ascidian oocytes. This communication presents the size relationships of the cell nucleus and nucleolus in two species of ascidians belonging to two different families, namely, *Ecteinascidia thurstoni* Herdman (Fam. Perophoridae : Enterogonia) and *Pyura* sp. (Fam. Pyuridae : Pleurogonia). *Ecteinascidia* is a viviparous form and *Pyura* is oviparous.

Fig. 1 presents the relationships of the diameter of the nucleolus, nucleus and the oocyte. In *Pyura* the oocyte grows to 150μ, while in *Ecteinascidia* it reaches 300μ in diameter. In both species, the diameter of the nucleus increases with increase in diameter of the oocyte. However, the increase in *E. thurstoni* is more striking than that in *Pyura*. In regard to the nucleolus in both species, there is an initial increase in size, which reaches the maximum —10μ diam.—when the oocyte has attained the diameter of 60μ in *Pyura* and 70μ in *Ecteinascidia*. There is no further increase in size of nucleolus after this and the curve levels off. The size relationships shown here for ascidian oocytes resemble those described for amphibian[5] and starfish[4] oocytes.

From these observations it would appear that, so far as can be judged by size, the nucleolus appears to be active only in the early stages of growth of the oocyte and not in the later stages. If the nucleolus plays any part at all in the synthesis of cytoplasmic proteins[1,2] it is clear that this activity is restricted to the early growth of the oocyte. Later contributions must come from some other source. Berrill[6] has posed the problem of the role of the follicle and 'test'

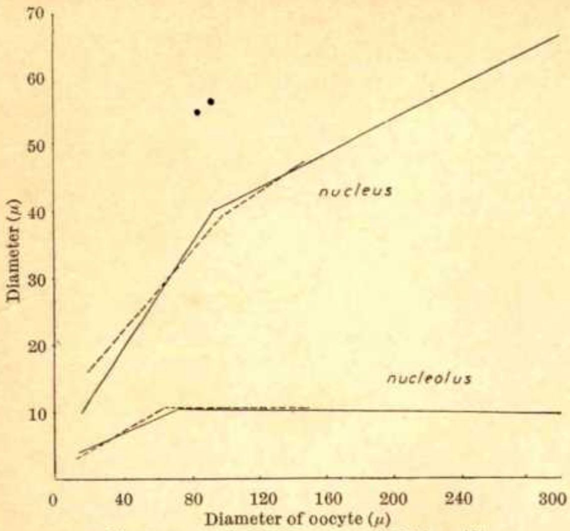

Fig. 1. ----, *Pyura*; ———, *Ecteinascidia*

cells in the growth of the ascidian oocyte. My observations on the later history of oocyte growth in both *Ecteinascidia* and *Pyura* lead me to believe that the activity of the nucleolus ceases, the follicle cells and 'test' cells take over, and, by their contributions, assist in the cytoplasmic synthesis. In these later stages, the outer half of the oocyte is filled with periodic acid–Schiff-positive substances, granules in *Ecteinascidia* and plaques in *Pyura*, and there is reason for believing that they come from the follicle and 'test' cells surrounding the oocyte. The periodic acid–Schiff reaction is indicative of the presence of protein carbohydrate complexes and it is highly probable that these are the predominant products of later synthesis.

A detailed study of the origin and nature of these substances is in progress and will be reported elsewhere.

I am indebted to Prof. B. R. Seshachar for his guidance and criticisms. Thanks are due to the National Institute of Sciences of India for awarding me a junior fellowship.

Effect of Colchicine on the Utilization of Thymidine labelled with Tritium during Chromosomal Reproduction

EXPERIMENTS[1] designed to verify the findings of Taylor, Woods and Hughes[2] on the incorporation of thymidine labelled with tritium in the deoxyribonucleic acid in chromosomes of growing root meristems of seedlings of *Vicia faba* have produced evidence that colchicine influences either the synthesis of the acid or its subsequent distribution among sister chromatids at metaphase. This evidence was derived from two types of experiment.

In the first, colchicine was not used and chromosomes with the sister chromatids both labelled were regularly found in metaphases and anaphases at 24 hr. after labelling and frequently also at 48 hr., that is, after approximately two cell cycles. Since after 48 hr. about 12 per cent of the metaphases contained some chromosomes labelled in both chromatids and others only in one, it was not of overriding importance to determine whether such nuclei were undergoing their first or second mitosis after the labelled thymidine was applied, though the indications were in favour of regarding them as second divisions.

In the second experiment, colchicine was used in the following way. Seedlings were grown in tap-water containing 0·05 per cent colchicine to which labelled thymidine was added 1 hr. later. This was replaced after 8 hr. by fresh tap-water with 0·05 per cent colchicine, and roots were fixed after 20 and 24 hr. In both samples autoradiographs showed some chromosomes labelled in only one chromatid already in the first mitosis after labelling. Closely similar results have since been obtained with concentrations of colchicine ranging from 0·025 to 0·1 per cent, treatment commencing 2 and 4 hr. before the application of labelled thymidine (Fig. 1).

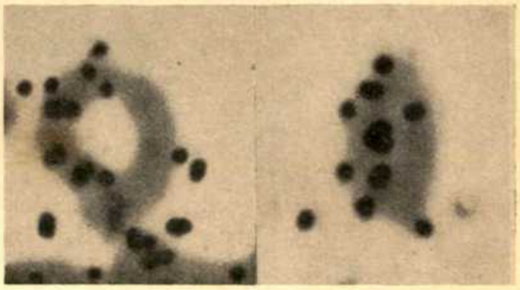

Fig. 1. Autoradiographs over *Vicia* chromosomes from *C*-metaphases at the first mitosis after labelling with ^{3}H-thymidine, showing labelling in one chromatid only. Left, from a root of a seedling grown for 2 hr. in 0·025 per cent colchicine in tap-water prior to treatment for 7 hr. with 0·025 per cent colchicine and ^{3}H-thymidine, followed by 0·025 per cent colchicine in tap-water for 13 hr. Right, after 4 hr. in 0·025 per cent colchicine; 0·025 per cent colchicine and ^{3}H-thymidine 7 hr.; 0·025 per cent colchicine 9 hr. Squash preparations stained in toluidine blue after autoradiography. (× 2,700)

These results seemed to contradict the findings of Taylor *et al.*, who reported that in their experiments all chromosomes were labelled in both chromatids at the first mitosis, while all were labelled in only one chromatid at the second mitosis. In a more recent publication, however, Taylor[3] reports two instances of chromosomes labelled in both chromatids in roots of *Bellevalia romano* in *C*-metaphases in the second division. The frequency of such chromosomes seems to be much lower than in our experiments on *V. faba* without colchicine. C. H. Ockey (personal communication), in agreement with our findings, has found chromosomes with sister chromatid labelling together with chromosomes labelled only in one chromatid in *V. faba* roots not treated with colchicine and fixed 40 hr. after labelling.

Woods and Schairer[4] grew seedlings of *V. faba* in nutrient solution containing labelled thymidine and 0·03 per cent colchicine for 12 hr. and compared them with plants grown in nutrient solution plus labelled thymidine for 8 hr. followed by nutrient solution with colchicine without labelled thymidine for 6 hr. Their experiment thus differs from our colchicine experiment in two important aspects: they omitted pretreatment for 1 hr. with colchicine

Table 1. RE-DISTRIBUTION OF NEWLY SYNTHESIZED DEOXYRIBONUCLEIC ACID
(Based on the experimental data of Woods and Schairer. 2 × 25 chromosomes each treatment)

Suggested ratio	1 : 1		1·5 : 1		1·75 : 1	
Treatment	χ^2	P	χ^2	P	χ^2	P
Control	43·61	0·72	23·44	>0·99	55·07	0·3
Colchicine	35·29	0·94	19·1	>0·99	45·91	0·5

The values for χ^2 for the ratios 1·5 : 1 and 1·75 : 1 were calculated on the assumption that the chromatid showing the higher number of grains represented the more heavily labelled one; the inverse probability of the more heavily labelled chromatid showing fewer grains was neglected. It is considered unlikely that the error thereby introduced should affect the conclusions.

to ensure that this agent was already active when labelled thymidine was added and the concentration of colchicine was lower than in our experiments. It should also be noted that the controls were kept in colchicine for 6 hr. after labelling and that the concentration of labelled thymidine was also different from ours. The extent to which these factors influence experimental results is under investigation.

Woods and Schairer counted grains in autoradiographs over 25 metaphase chromosomes in each sample and found by the chi-square test that their results were compatible with equal re-distribution of newly synthesized deoxyribonucleic acid among the sister chromatids at metaphase. We have examined the statistical significance of their results (Table 1). Since the chi-square tests obviously do not exclude the possibility of the re-distribution of newly formed deoxyribonucleic acid being in any ratio between 1 : 1 and 1·75 : 1 it has to be concluded that their results are not sufficiently accurate either to detect a change due to colchicine in this ratio within the limits stated or to contradict previous results by Plaut and Mazia[5], even if experiments on *V. faba* could be regarded as conclusive for *Crepis*. It is of interest to note that Plaut and Mazia calculated 2–3 sub-units per chromosome, which seems to agree well with the fit obtained for a factor of 1·5 : 1 in Table 1.

Woods and Schairer suggest that our observation of chromosomes with singly labelled chromatids at the first mitosis in roots of *V. faba* treated with colchicine is due to neglect of the influence on observations of absorption of β-particles in chromatids separated from the film by a layer of cytoplasm or other organic matter. The much-discussed short range of β-particles emitted by tritium was known to us when the autoradiographs were analysed and all chromosomes showing singly labelled chromatids were checked and doubtful ones rejected. Ockey (personal communication) and ourselves have found that the autoradiograph due to one labelled chromatid is still continuous where it is crossed by an overlying unlabelled chromatid. Although such differences in level can easily be seen by focusing, such chromosomes would certainly have been rejected by us. For these reasons, which inevitably introduce a certain element of subjectivity, and because of the foreseeable low accuracy, no grain counts were undertaken. It should be stressed that we never suggested that colchicine might affect the distribution of new deoxyribonucleic acid in all chromosomes; the claim was that chromosomes labelled in only one chromatid were found in significant numbers in metaphases at the first mitosis under the conditions of our experiment. In this sense the results of Woods and Schairer merely show that among the 50 chromosomes (that is, the complement of slightly more than four complete nuclei) which they accepted for grain counts no chromosome labelled in only one chromatid was found.

BIOLOGY

Observations by Electron Microscopy on the Structure of an Acephaline Gregarine (*Apolocystis elongata*, Phillips and MacKinnon)

Apolocystis elongata lies in the seminal vesicles of the worm *Eisenia foetida* (Sav.). As we have seen by light microscopy, *Apolocystis* possesses a cuticle thickly covered by a pile of short hair-like processes each about 4μ long and 0·5μ thick. The processes do not show obvious signs of movement. The animal is a passive feeder. In our investigation by electron microscopy we have been particularly interested in determining the ultra-structural organization of the body-wall and hair-like processes.

Trophozoites of *Apolocystis* were fixed in 1 per cent osmium tetroxide solution buffered to *p*H 7·3[1], and embedded in a 3 : 1 mixture of *n*-butyl and *n*-methyl methacrylate. Ultra-thin sections were cut with a glass knife, mounted on to copper grids previously covered with a carbon film and examined with a Siemen's Elmiskop 1*a*.

The surface of the gregarine is covered with a thin, highly osmiophilic layer about 100 A. thick which covers a sheet-like array of vesicles, about one vesicle in depth. Each vesicle is about 200–300 A. in diameter and its limiting membrane is about 50 A. thick. The vesicles lie close to each other, so that in cross-section the body-wall appears to be delimited by a double membrane, the outer one corresponding to the membrane first described above and the inner one to the limiting membranes of the vesicles. Tangential sections through the body-wall show that the vesicles are arranged alternately. The general impression gained from such sections is that the body-wall is honeycombed with minute pores although, at present, we have no evidence that they are true pores in the sense that they open to the exterior and place the interior of the body in direct communication with the environment.

The electron microscope has revealed that the hair-like processes seen by light microscopy are simply finger-like evaginations of the body-wall (Fig. 1). The surface of each process has the same ultra-structural organization as the body-wall. Tangential sections through the surfaces of the 'hairs' reveal the honeycomb arrangement of the vesicles described above most clearly (Fig. 2). The interstices of the vesicles are filled with a weakly osmiophilic substance. Oblique sections through the long axis of the 'hairs' show what appear to be elongate fibres with cross-banding. Careful examination at high

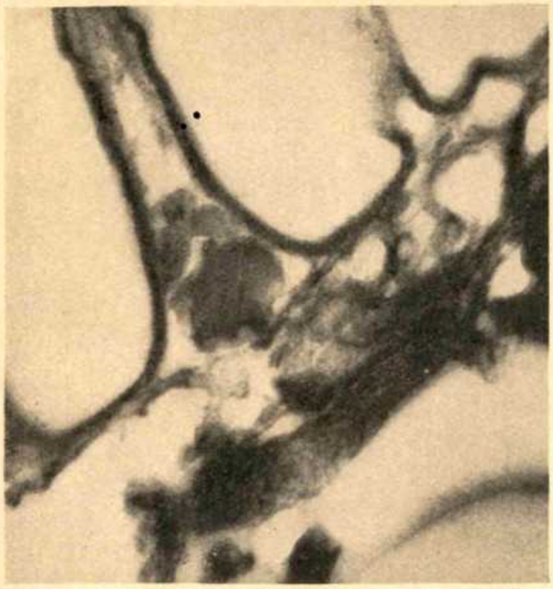

Fig. 1. Micrograph showing that the 'hairs' seen by light microscopy are finger-like evaginations of the body wall. At the base of one of the 'hairs' is a dense body of irregular outline and three smaller inclusions. Beneath the body wall is a membranous reticulum which in one region is concentrated to form an elongate body. (× 40,000)

resolution, however, shows that such 'fibres' are simply chains of vesicles, that is, the plane of section had passed through part of the wall. This interpretation is confirmed by the absence of fibres or any other osmiophilic content when the hair-like processes are seen in cross-section. In some micrographs we have observed a very dense osmiophilic granule of irregular outline and two or three smaller, and less-dense, spheroidal inclusions lying at the base of a 'hair' and projecting into it.

Functionally the hair-like processes seem to be a means of increasing the body-surface of the animal, thereby facilitating intake of nutriment and oxygen and elimination of waste products. The vesicles which lie in the body-wall probably serve essentially the same function.

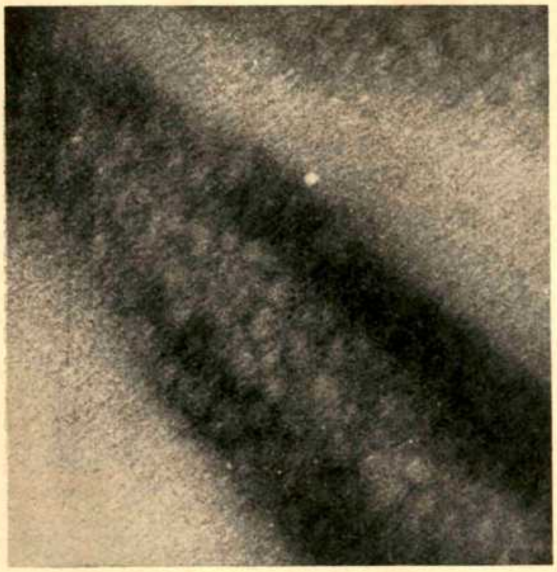

Fig. 2. Tangential section through the wall of a 'hair' to show the honeycomb arrangement of the small vesicles described in the text. (× 160,000)

Beneath the body-wall, underlying the vesicular system, is a complex network of membranes embedded in a homogeneous slightly osmiophilic substance (Fig. 1). The membranes and accompanying substance are generally separated from the vesicles by a clear (non-osmiophilic) zone of variable depth of the order of about 1μ. Each membrane is about 100 A. thick. Compared with inclusions seen in metazoan cells the network of membranes most closely resembles the endoplasmic recticulum[2]. Examination of light microscopical preparations of *Apolocystis* shows that the region occupied by the membranes and accompanying substance is strongly basophilic ; the same has frequently been reported for regions containing much endoplasmic reticulum. However, in the latter case the basophilia is generally attributed to fine particles[2,3] which occur close to, or in contact with, membranes of the endoplasmic reticulum. In *Apolocystis* the basophilia is due either to the membranes or to the accompanying homogeneous substance, or to both.

In some regions the membranes and accompanying substance are concentrated in the form of spheroidal or elongate bodies which appear to be similar to mitochondria seen in micrographs of other tissue. Occasionally, many dense granules of irregular outline, of the same type as seen in the base of the 'hairs', lie enclosed by the meshes of the membranous network. Larger inclusions, spheroidal in shape and about 1μ in diameter, also occur within the meshes of the network.

Within the remainder of the animal occur many large vacuoles, each with a smooth limiting membrane about 50 A. thick. Examination of light microscopical preparations stained by Best's carmine method shows that such 'vacuoles' correspond to inclusions containing glycogen (glycogen grains). Between the 'vacuoles' lie extensions of the membranous system and inclusions referred to above. Occasionally, we have observed groups of membranes and small vacuoles (= dilations or paired membranes) which together resemble the Golgi apparatus seen in other Protozoa and in various Metazoa[4].

The nucleus is variable in position and consists of two main components, a prominent nucleolus and a peripheral zone. The nucleolus is very dense in appearance being composed of numerous small, highly osmiophilic granules. Within the nucleolus are several large vacuoles. The peripheral zone of the nucleus consists of strings of osmiophilic material lying within a 'clear' matrix. The nuclear contents are bounded by a double membrane, a feature which appears to be a characteristic of nuclei throughout the animal kingdom.

We are grateful to the Wellcome Trust for a grant to purchase an electron microscope and to St. Bartholomew's Hospital and Medical College, and the University of Hull, for further financial help and facilities.

Pogonophora in the Hardangerfjord, Western Norway

Until recently, Pogonophora were known only from the north-western Pacific and from Indonesia. All species being found in the deep sea such a limited distribution seemed unlikely, the more so as the tubes of the animals are hair-like and easily overlooked. In fact, new investigations and revision of old collections have proved that the Pogonophora are widely distributed and also occur in relatively shallow water. Thus one species is now known from the Polar Sea, and Kirkegaard found Pogonophora in the *Galathea* collections from Indonesia[1] and from the Gulf of Panama[2]. Jägersten[3] described *Siboglinum ekmani* from old collections from about 500 m. in the Skagerrak, and he also described the larva of another species from only 180 m. depth in the same area[4]. Kirkegaard[5] re-investigated the deepest parts of the Skagerrak and found more material of *S. ekmani*, and Southward[6-8] has obtained several species from the continental slope south-west of England and west of Ireland.

As the fauna of the Norwegian Deep in the Skagerrak comprises many typical deep-sea animals which also live in the deep Norwegian fjords, Pogonophora could be suspected to occur in our rich collections from the Hardangerfjord. Several samples of undetermined narrow tubes were re-investigated. Between them were found many still more slender, red-brown tubes up to 17·5 cm. long and strongly resembling those of *Siboglinum ekmani*. New dredgings in different parts of the Hardangerfjord have proved this species to be fairly abundant in depths between 396 and 840 m.

The material has been sent to Prof. G. Jägersten, who has confirmed that part of it is very similar to *S. ekmani*, whereas one animal probably belongs to another species. Thus at least two species of Pogonophora seem to occur in the Hardangerfjord.

Utilization of Nutritive Spheres in the *Proteus* Group of *Amoebae*

In all members of the *proteus* group of *Amoebae*[1] there occur spherules of a pale blue colour to which the name 'excretion spheres' was given by early writers. This designation was changed to "nutritive spheres" by Hayes[2] in 1924. The reaction of these bodies to various reagents has been described in an appendix by Hayes to Taylor's paper entitled "*A. proteus*, some New Observations on its Nucleus Life History and Culture", and further information about them was later published by Taylor[3].

The diameter of these bodies is proportional to the age of the *Amoeba*. A quick examination of the nutritive spheres enables the observer to distinguish a newly metamorphosed *Amoeba* from an adolescent, mature or senile creature. It is necessary here to emphasize the importance to the reader of stating the age of the *Amoeba* when describing its reactions, behaviour, etc. Reaction to a certain stimulus characteristic of mature *Amoebae* may be very different from that of an adolescent. To repeat: the diameter of the nutritive spheres is a criterion of the age of the *Amoeba*, which should always be given.

In my paper[2] I used a hæmatoxylin which stained the nutritive spheres purple. In this account it was shown that during the differentiation of the spores in the adult *Amoeba* the nutritive spheres were gradually used up, so that those *Amoebae* which were full of spores could be picked out by the extreme scarcity of coloured nutritive spheres, the degree to which sporulation had proceeded being indicated by the number of nutritive spheres present.

In sections through sporulating *Amoebae*, nutritive spheres which had begun to yield up their contents looked like collapsing balls, every stage from a fully inflated to a completely collapsed sphere being found.

Recently, I have seen this phenomenon in living material. Under natural conditions the *proteus* group[1] are mature and senile in the winter months. If these mature specimens, easily identified by their large nutritive spheres (7μ), be placed in a Petri dish and kept under observation, the gradual loss of contents of the nutritive spheres, as sporulation proceeds, can be witnessed; deformed spheres of every kind, that is to say, spheres having given up varying volumes of their contents, can be picked out.

Second Flowering in *Oryza sativa* (var. *indica*)

In India rice is normally harvested when ripe by cutting off the leaves and stems near ground-level. Shortly before this operation the field is allowed to dry. There is very little regeneration, though it is well known that rice can be propagated vegetatively by 'ratooning'. In 1958 three small plots of 5·2 square metres each at Giridih in Bihar were planted with the *aus* (rapidly maturing) variety *CH*-10 in July. Owing to the late monsoon the crop was poor. Instead of drying and cutting as usual, the plots were not allowed to dry, and the ears were plucked by hand on October 10. The plots produced a second crop which was harvested on November 23 by the usual method. Table 1 shows the yield of paddy for two harvests of the three plots.

The total yield was thus increased by 117 per cent, that is to say, more than doubled. The second crop was harvested at the same time as the *aman* (slowly maturing) rice in the neighbouring plots.

Table 1. Yield of Paddy (dry weight, gm.) for Three Plots each 5·2 square metres in Area for the First and the Second Crop

Plots / Yield	1	2	3	Total
First crop	2·3	605·4	673·0	1,280·7
Second crop	660·2	650·8	187·8	1,498·8

Regeneration was found to occur in two ways—through the formation of new tillers at the base and new branches at some nodes of the stems of the harvested plants. Both the new tillers and the new branches flowered and thus produced the second crop.

Experiments are being made this year on a large scale with numerous varieties to determine the economic value of this method of harvesting.

Control of Leaf Senescence by Auxins

THE considerable knowledge which has accumulated over the past thirty years suggests that differentiation, growth and senescence of plant cells is closely linked to the auxin status of the tissue. Investigations by Shoji, Addicott and Swets[1] have shown that differentiating and enlarging tissues of the green leaves of Black Valentine bean contain a relatively high concentration of an extractable auxin. These levels decrease as the tissues mature and at senescence only small amounts of the auxin are detectable.

Although mature parenchymatous tissues can often be stimulated experimentally into renewed growth and cell division by supplying an auxin, the changes which take place in highly differentiated cells, such as the mature mesophyll of the leaf, are normally irreversible and their senescence and death are inevitable.

Recent work has now shown that the ageing processes in leaves can be arrested by treatment with certain chemicals, and in this way particular physiological states have been maintained for considerable periods of time. For example, Richmond and Lang[2] have shown that chlorophyll and protein breakdown and the associated loss of green colour in detached leaves of *Xanthium* can be retarded by treatment with kinetin, with a resulting extension of the life of the leaf. Person, Samborski and Forsyth[3] have found similar effects following the treatment of detached wheat leaves with benzimidazole. Brian, Petty and Richmond[4] have reported that both the natural autumnal yellowing and the subsequent leaf fall of a number of temperate deciduous trees have been delayed by spraying gibberellic acid on to the leafy branches.

From the work carried out in this Unit over a number of years it is clear that the ability to arrest physiological changes associated with leaf senescence is not a property only of kinetin, benzimidazole or the gibberellins. Synthetic auxins of the chlorophenoxyacetic acid group must also be considered. It has already been shown[5] that the natural and continuous fall in pectin methylesterase activity which occurs in the abscission zones of growing petioles of *Phaseolus vulgaris* can be prevented by treatment with 2,4-dichloro- or 2,4,5-trichloro-phenoxyacetic acids (2,4-D or 2,4,5-T) and that under these conditions, abscission and senescence of the petiolar tissues is prevented. The application of 2,4,5-T to the leaf blades of certain tropical trees has produced differential senescence within the treated leaves[6]; with suitable doses the areas immediately below the applied droplets remain permanently green and healthy while the surrounding areas become progressively yellow and senescent.

It has now been clearly demonstrated that the application of a suitable formulation of either 2,4-D or 2,4,5-T will prevent normal senescence in both attached and detached leaves of a number of temperate deciduous species. Most of the experiments have been done with *Prunus serrulata senriko* and the following procedure was adopted. During the months of October and November a drop of ethanol solution of the butyl ester of 2,4-D or 2,4,5-T was applied to the lamina on either side of the main vein to give a total dose per leaf ranging from 10 to 100 μgm. After this treatment an apparently normal yellowing and senescence occurs in the untreated areas, but in the cells of the tissues directly below the applied drop the plastids retain their chlorophyll so that, at the time of normal leaf-fall at the end of November, each treated area remains as an isolated green spot about 1 cm. in diameter surrounded by yellow tissue. With detached leaves similarly treated and kept in high humidity in the light, the untreated parts of the blade and the control leaves become entirely yellow within twelve days, while the islands of 2,4-D-treated tissue remain green until general autolysis starts some 10–20 days later.

If the leaves are treated with a radioactive butyl ester of 2,4-D, labelled with carbon-14 in the carboxyl group, the autoradiographs of the whole leaf made at various intervals after the application show that the majority of the radioactivity is initially concentrated immediately below the treated areas with only traces of activity over the remainder of the blade. This pattern of distribution remains unaltered in detached leaves, but a week after attached leaves have been treated no radioactivity can be detected in the untreated portions of the blade; activity is then confined to the areas below the drops and eventually corresponds to the areas of tissue which remain green.

The colour of the islands of green cells is not due to an immobilization of chlorophyll in an inactive form. When the leaves treated with 2,4-D are illuminated and supplied with carbon-14 dioxide a ready fixation of carbon-14 occurs in the green areas beneath the applied 2,4-D, while fixation in the surrounding yellowing tissue is negligible and of the same order of magnitude as that in a yellowing control leaf.

Respiratory studies on disks of leaf tissue have shown that the treated areas which remain green retain a relatively high oxygen uptake which equals that of an untreated green leaf, while oxygen uptake in the surrounding yellowing tissue falls progressively for many days after the application of 2,4-D and follows that in a yellowing control leaf.

Preliminary analyses of the nitrogen fractions in the treated leaves indicate that the level of alcohol-insoluble nitrogen remains higher in the green 2,4-D-treated areas than in the surrounding yellowing tissue, suggesting that there may be an effect on protein conservation similar to that described for kinetin and benzimidazole.

The evidence for the maintenance of chlorophyll and of photosynthetic activity in leaf tissue following the application of high doses of 2,4-D is of particular interest, since previous reports by Wedding, Erickson and Brannaman[7] and Akers and Fang[8] have described depressions in photosynthesis following treatment with synthetic growth-regulators. Maciejewska-Potapczyk[9] records an actual reduction of 25–40 per cent in the chlorophyll content of leaves four days after treatment with 2,4-D, and Moreland, Hill and Hilton[10] have recently found that certain phenoxyacetic acids, including 2,4,5-T, have an inhibitory effect on the photochemical Hill reaction in isolated chloroplasts.

The responses which occur in both plant growth and cellular metabolism following applications of auxins are usually considered as a departure from the control pattern. The results presented here show that, under certain conditions, 2,4-D and 2,4,5-T tend to maintain unchanged particular physiological states within the cells and thereby delay the normal changes which take place during senescence. These results thus provide a further example of the control of physiological ageing by auxins.

I am indebted to Prof. W. O. James, Dr. Mary Halloway, Dr. D. C. Smith, Mr. R. G. Powell and Dr. C. C. McCready for their co-operation in this work, and I wish to thank Prof. G. E. Blackman for his constant interest and encouragement. Further details will be published elsewhere.

A New Nitrogen-fixing Micro-organism producing a Red Pigment

WHILE isolating strains of *Rhizobium lupini* from the nodules of *Lupinus luteus* grown on the acid sandy soil of the Nyirség area in north-eastern Hungary, I succeeded in isolating, on a *Rhizobium* medium, two red micro-organisms. These have been labelled *Pr* and *E*.3. They came from places several miles apart. The plants from which the *Pr* and *E*.3 strains derived were in a state of fluorescence and conspicuously larger than the surrounding lupins.

The new micro-organisms are spherical or ovoid cells, 4–6μ in diameter. During their growth, 2–4 spherical, strongly refringent granules appear in the cells. A daughter cell becomes detached without a sterigma developing. In aged cultures large spherical cells with diameters between 8 and 9μ can be seen in which, besides the above-mentioned granules, 5–10 additional similarly shaped but smaller granules develop.

The new micro-organisms form a slowly migrating smooth colony on agar slants, with a strong adhesion to the nutrient medium.

The cell-wall gives a good response to most of the usual stains. Carmine acetic acid stains one point of the cell-wall.

Glucose, maltose, saccharose, lactose, mannitol and salicin are decomposed by the new strains with an intensive production of acids, but without the development of gases. They produce urease and do not liquefy gelatine. They produce no hydrogen sulphide and do not reduce nitrates to nitrites. They can utilize ethanol as their only source of carbon. Placed on a bean extract containing a 3 or 6 per cent solution of ethanol they will proliferate intensively. A temperature of 16° C. ensures vigorous growth, the optimum temperature being 25–28° C. Washed off the culture medium and exposed to ultra-violet rays they give a blue fluorescence. Diffused light promotes proliferation and pigment production. They are resistant to streptomycin, which does not impair their pigment production. Low concentrations of ammonium chloride, ammonium sulphate, potassium nitrate and peptone promote growth and the development of red pigment. The *p*H of culture media adjusted to 7 is reduced by them to 5·2–4·2 within 48 hr. They grow satisfactorily and continue to produce red pigment even in media containing 0·3 per cent citric acid, with a *p*H less than 3. Placed in stab cultures and examined otherwise they were found to be obligate aerobes.

Both strains develop satisfactorily on yeast, bouillon and bean agar, and fix atmospheric nitrogen without symbiosis while producing red pigment. To be able to do so the presence of a nitrogen-source in the nutrient medium is indispensable.

The properties described justify the claim that two varieties of a new kind of *Saccharomyces* have been discovered: the only difference between them is that the red pigment produced by strain *Pr* is brighter than that produced by *E*.3. No taxonomical allocation has yet been made.

The increase in nitrogen per unit of glucose consumed has been studied in numerous experiments on a bean-soup medium which in some cases had been aerated. Results were invariably positive. The significant experiments, which were repeated several times, showed the nitrogen increase to be 2·4–5·7 mgm. nitrogen/gm. glucose. Culture flasks through which air had been passed gave the higher value.

The results obtained from four different treatments (each repeated three times) are given in Fig. 1.

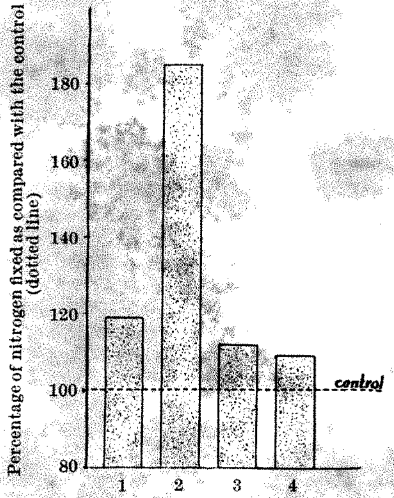

Fig. 1. (1) Bean soup (a 5 per cent decoction of white beans containing 2 per cent glucose, 0·3 per cent sodium chloride and 0·2 per cent potassium dihydrogen phosphate). Aerated during cultivation with a vacuum pump and sterile air. 40 ml. per culture flask. (2) 40 ml. of bean soup added to 80 ml. of 0·3–0·8 mm. diameter sterilized quartz sand. (3) 40 ml. of bean soup added to natural washed, finely granulated, sterilized sand. (4) As (3), but unsterilized. The bean soup was inoculated with 1 ml. of suspended *Pr*-strain. Sterilization was carried out in an autoclave for 20 min. at 2·5 atm. Nitrogen fixed was determined by Kjeldahl's method

That the value obtained in (4) is inferior to that in (3) is presumably due to the presence of antagonistic micro-organisms in the unsterilized sand as, otherwise, there was no difference between the two soils.

There was a correlation between the degree of nitrogen fixation and the red colour. This suggested that the red pigment may have a role in fixing atmospheric nitrogen similar to that of leghæmoglobin, which occurs in the nodules of leguminous plants and is known to be involved in symbiotic nitrogen fixation. The determination of a relationship between leghæmoglobin and the red pigment would be very useful in elucidating the chemical mechanism of atmospheric nitrogen-fixation.

Investigations with this end in view have been started in the Institute for Organic Chemistry at Szeged, and experiments performed under the supervision of G. Fodor by B. Matkovics produced the following results: (1) The red colour of the pigment produced by strain *Pr* is due to a hæmoprotein related to hæmoglobin as shown by the ultra-violet spectroscopic data of J. Hires; (2) a porphyrin ester from leghæmoglobin has been prepared[1].

Investigations on the exact structure of the pigment from strain *Pr* are being carried out by G. Fodor and co-workers in the Stereochemical Laboratory of the Academy, Budapest.

Preparation of Autoradiograms for Electron Microscopy

FREQUENTLY when examining autoradiograms of biological specimens there is a need for resolution such as can be obtained with the electron microscope. A technique for preparing autoradiograms for electron microscopy has been reported by Liquier-Milward[1]. The method described here has the advantage of being somewhat simpler in that nuclear emulsion is applied directly to the specimen grids, and the method is suitable for use with ultra-thin sections. Although only results obtained with yeasts and the alpha-emitter polonium-210 are described, other isotopes and biological specimens can be used.

Yeast cells, previously suspended in a polonium-210 solution, were fixed with 2 per cent osmium tetroxide containing 0·8 per cent sodium chloride[2]. The fixed cells were dehydrated in a graduated series of ethanol concentrations and embedded in methacrylate. Good results were obtained with a mixture of four parts N-butyl methacrylate and one part methyl methacrylate[3]. Ultra-thin sections were cut with a Porter–Blum microtome, transferred to carbon-coated specimen grids, and allowed to dry thoroughly. All subsequent steps were carried out under light filtered through a Wratten series *OA* filter. Alpha-sensitive Eastman Kodak *NTA* emulsion in gel form (obtained through the courtesy of the Eastman Kodak Co., Rochester, N.Y.) was heated at 45° C. until fluid. A drop of the liquid emulsion, either full strength or diluted 1 : 1 with distilled water, was transferred to a clean glass slide. Specimen grids were coated by touching them to the drop of emulsion. Occasionally the yeast sections floated off when contact was made with the emulsion. This was due to insufficient drying of the grids before emulsion was applied. After coating, the grids were placed in a light-tight box containing a small vial of anhydrous calcium sulphate and exposed for 3–4 weeks at 4° C. The autoradiograms were developed for 15 min. in Eastman Kodak *D*-19 developer, fixed in acid fixer for 5 min., washed thoroughly in running tap water, and finally rinsed in distilled water. After drying they were examined with an *RCA EMU-2C* electron microscope.

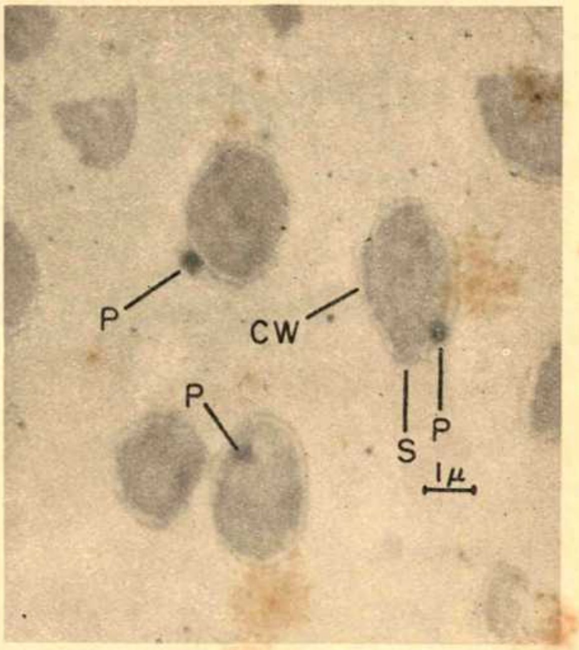

Fig. 1. Electron micrograph of autoradiogram showing distribution of polonium-210 on yeast cells. *P*, Polonium track; *CW*, cell wall; *S*, bud scar

Typical results are shown in Figs. 1 and 2. It is apparent that the emulsion obscured some cellular detail; however, in spite of this, good autoradiographic resolution of the location of polonium-210 in the cells was obtained. There was no evidence that

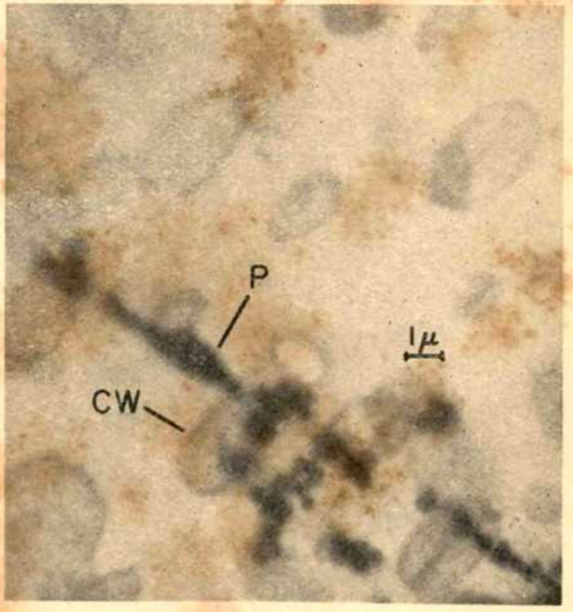

Fig. 2. Electron micrograph of an alpha track from polonium-210 on yeast cells. Key as in Fig. 1

sectioning caused displacement of the radioactivity. Due to the thinness of the film, only those particles which travelled at angles estimated to be less than 1° from horizontal were recorded as typical alpha tracks. Actually, this was an advantage since long tracks did not give the autoradiographic resolution that shorter ones did. A comparison of the figures illustrates this. In Fig. 1 the location of polonium-210 is much better defined than in Fig. 2. Radioactivity was almost entirely located on the surface of the cells, although a few were found to have polonium-210 in the cytoplasm (Fig. 1). This suggests that yeasts are nearly impermeable to this element. Further details on the distribution of polonium-210 and other heavy metals in yeast cells will be reported elsewhere.

This work was performed under Contract No. *W*-31-109-Eng-52 between the Atomic Energy Commission and the General Electric Co.

PHYSIOLOGY and BIOCHEMISTRY

Use of 'Tremorine' for screening Anti-Parkinsonian Drugs

'TREMORINE' (1 : 4-dipyrrolidine-butyne) has been proposed[1,2] as a test drug against which anti-Parkinsonian agents may be screened and evaluated by their effect on the tremor induced by 'Tremorine' in mice. We have investigated the action of the compound in toads, mice, rats and guinea pigs; trials with larger animals, dogs and cats, were restricted by the shortage of 'Tremorine'.

The incidence and intensity of the symptoms caused by an effective, non-lethal dose of 'Tremorine' (*LD*5 or lower) varied with the species. Toads survived high doses (150 mgm./kgm.) without showing any constant characteristic symptoms other than transient excitation and occasional 'yawning', possibly indicating some discomfort in the respiratory passages. The mammals tested all showed a similar pattern of response. The *LD*50 for mice was of the order of 65 mgm./kgm. subcutaneous and 3–5 mgm./kgm. intraperitoneal; for rats 75 and 15 mgm./kgm. respectively, for guinea pigs 25 and 2·5 mgm./kgm. respectively. The effective dose, causing characteristic symptoms persisting for a few hours, was about one-quarter of the *LD*50. This dose was high enough to cause an occasional death. All animals tested exhibited within 15–30 min. of 'Tremorine' injection salivation, diarrhœa, occasional or persistent fine tremors of fore-limbs and head at the rate of 7–10 per sec., occasional single jerks or even convulsions, hypothermia and some analgesia. The present investigation was mainly concerned with the Parkinsonian-like tremors, and hypothermia was prevented by keeping the animals warm. The analgesic effect in mice has been dealt with by Chen[3] and electroencephalographic studies in cats have been made by Kaelber and Correll[4].

At the height of the drug effect, the animals were visibly ill, stretched out flat and unwilling to move, though responsive to stimuli and apparently fully aware of their surroundings. When moving, their limbs were often extended and stiff. Strutting of the fore-limbs or biting on the food tins or the wires of the cage may possibly be interpreted as behaviour aimed at negating the tendency to tremors.

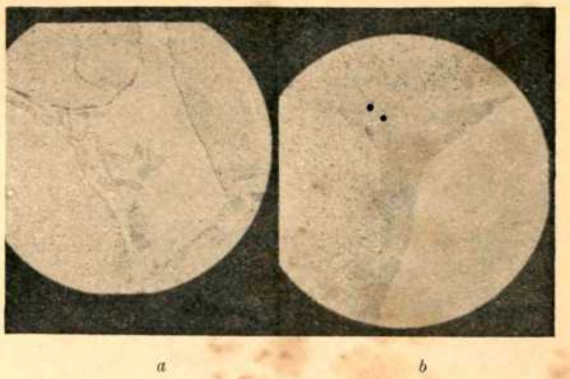

Fig. 1. From guinea pig killed 160 min. after injection of 70 mgm./kgm. 'Tremorine' subcutaneously. *a*, Intraventricular hæmorrhage; *b*, hæmorrhage on the surface of the cortex between gyri. Photomicrographs by courtesy of Dr. J. Mackiewicz

Typical persistent tremors were seen only in mice. In guinea pigs profuse salivation was most marked; in general, these animals appeared to be more prostrated than mice and tremors could often be demonstrated only when the animal was induced to move. The most impressive sign in rats was sanguineous lachrymation together with salivation and diarrhœa of the same nature as that caused by 0·5 mgm./kgm. carbamylcholine intraperitoneally.

The incidence of death at doses less than the *LD*50 was variable. Some animals died within 30 min. of injection, some died hours later after they appeared well on the way to recovery, while others died after 24–30 hr. in a prolonged coma, or in their sleep. Of those who died early, about 30 per cent had sudden, strong convulsions just before death, while the rest showed merely increasing sluggishness and weakness. Some animals recovered after they had already been recorded as dying. On post-mortem examination almost all animals, whether they died early or late, had injected brain vessels, and often visible hæmorrhages in the hemispheres or small blood clots in the ventricles (Fig. 1), 80 per cent had gross hæmorrhages as well, mainly subdural at the base of the brain or the brainstem, intrapericardial, intrapleural or intraperitoneal. A few retroperitoneal hæmorrhages were observed. It appeared that convulsions were present mainly in animals with cerebral hæmorrhages, but were absent with other internal hæmorrhages. Some intestinal hæmorrhages were also observed.

Repeated administration of sublethal doses of 'Tremorine' at intervals of 24–48 hr. did not produce convincing evidence of tolerance or cumulation, but it seemed that tremors and other motor disturbances were reduced while salivation and diarrhœa remained unaffected. (For this observation the animals were used only once, and kept at room temperatures above 16° C. throughout the experiment and the observation time.)

Atropine was found to be the most potent of all antagonists tried. In guinea pigs (*LD*50 of atropine sulphate about 400 mgm./kgm. intraperitoneally) 1–2 mgm./kgm. intraperitoneally prevented all symptoms if injected 20–30 min. before 'Tremorine', and abolished them within 10–15 min. if administered after full development of the 'Tremorine' symptoms. The corresponding dose for the amino-alkyl ester 'Parpanit' was 25 mgm./kgm., and for the amino-alcohol 'Kemadrine' 17 mgm./kgm. The same effect was observed in mice. In rats no difference in the effect of antagonists could be noted whether the salivation and lachrymation were induced by 'Tremorine' or by carbamylcholine.

Everett's observation that the quaternary amino-alkyl ester 'Methantheline' (Banthine) in mice antagonizes the secretory symptoms preferentially without noticeably affecting the tremor was confirmed. The quaternary atropine-homologue propionylatropine-methylnitrate, 2–3 mgm./kgm. intraperitoneally, showed the same preferential antagonistic effect in mice, rats and guinea pigs. It must, however, be noted that in all animals recovering from 'Tremorine' alone, the tremors and other muscular symptoms persisted after diarrhœa and salivation had ceased, and could often be demonstrated on the following day when the animal had in all other respects completely recovered.

Another atropine homologue, tiglyl-pseudotropine ('Tigloidine'), which in clinical trials[5] had proved to be effective against Parkinsonian and related extrapyramidal disorders while lacking the *p*-sympathicolytic action of atropine, showed in weak doses only doubtful antagonistic effects against 'Tremorine'. At high doses of both compounds it even appeared that their toxic effects were potentiated; in some experiments all animals, mice, rats or guinea pigs which had received the combined medication convulsed and died, while the controls survived; the 'Tigloidine' controls without any noticeable symptoms, and the 'Tremorine' controls with the usual diarrhœa, salivation and muscular disturbances.

On these observations it does not appear to be justified to separate the tremor effect induced by low doses of 'Tremorine' in mice from the diarrhœa, salivation and other effects seen in all animals tried. These latter effects are notably absent in cases of Parkinsonism and related disorders. Furthermore, in animals practically recovered from 'Tremorine', tremors can usually be elicited if the animal is disturbed, while the typical Parkinsonian tremor is a tremor at rest. It would seem that 'Tremorine' is best classed with the group of *p*-sympathicomimetic drugs which all cause to a varying degree increased glandular secretion, gastro-intestinal motility and muscular over-activity ranging from tremors to convulsions. To all of these atropine and related compounds are common and highly effective antagonists. The fact that these antagonists are beneficial in Parkinsonism and related disorders may indicate that there is some relationship between these disorders, but it does not prove or even suggest that they are identical. It is doubted whether the 'Tremorine' and related tests can justifiably be presented as tests for anti-Parkinsonian drugs.

Excessive Uric Acid Production in the Human induced by 2-Ethylamino-1,3,4-thiadiazole

An excessive endogenous synthesis of uric acid is present in a substantial portion of patients with gout[1]. The precise nature of the metabolic defect responsible for such excessive production is not known, but may be the result of a defective homœostatic mechanism for control of purine synthesis. Evidence for the existence of such a mechanism in the normal human has come from the observation[2] that the simultaneous administration of 4-amino-5-imidazolecarboxamide suppresses *de novo* purine biosynthesis from glycine-^{15}N. Factors affecting uric acid synthesis in the human are therefore of special interest in regard to the study of gout.

The administration of 2-ethylamino-1,3,4-thiadiazole to human subjects as treatment for cancer results in a several-fold increase in both the excretion of uric acid in the urine and the serum urate-levels[3]. An increased purine biosynthesis was proposed to account for this observation, but an increased urate production and an elevation of serum urate has also been observed to accompany lysis of leukæmia cells during therapy[4], and destruction of other tissues could conceivably give similar results. A definitive experiment to rule out one of these alternative explanations was needed.

We have confirmed the original observation that the administration of ethylaminothiadiazole does result in a substantial increase in serum uric acid-levels accompanied by a two- to five-fold increase in urinary uric acid excretion. By measuring the incorporation of glycine-1-^{14}C into urinary uric acid in the presence and absence of ethylaminothiadiazole, we have been able to demonstrate that this increased uric acid excretion is accompanied by an increased incorporation of carbon-14 into uric acid (Fig. 1). Since uric acid arising primarily from degradation of tissue purines would tend to dilute the isotope in newly formed purines and give rise to a lower specific activity of uric acid, the present findings indicate a marked stimulation in the *de novo* synthesis of purines as a result of ethylaminothiadiazole action. The cumulative incorporation of the isotope into uric

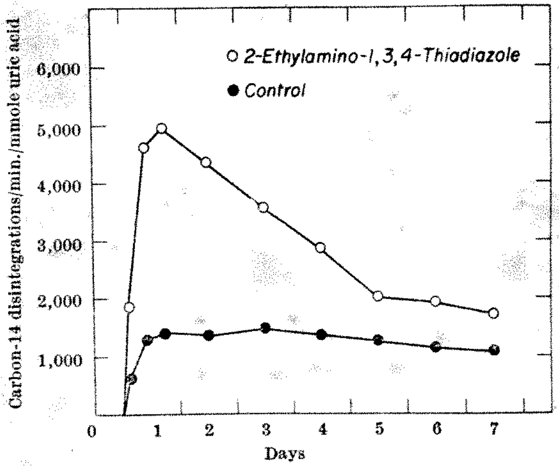

Fig. 1. Increased incorporation of glycine-1-^{14}C into urinary uric acid resulting from the administration of 2-ethylamino-1,3,4-thiadiazole to a non-gouty subject. 5 μc. of glycine-1-^{14}C was given orally at the beginning of each study and uric acid was isolated from the urine (ref. 2). A total of 350 mgm. of ethylaminothiadiazole hydrochloride was given in divided dose over a two-day period beginning one day before the second study

acid over a seven-day period was more than four times that observed in a similar period in the absence of ethylaminothiadiazole. The pattern and extent to which glycine-1-^{14}C was incorporated into uric acid in the presence of ethylaminothiadiazole with a maximum incorporation on the first day is very similar to the pattern of incorporation observed in many gouty subjects[5].

Some of the biological effects ascribed to ethylaminothiadiazole can be prevented by the simultaneous administration of nicotinamide. The carcinostatic action in experimental tumours in mice is diminished by nicotinamide[6]. We found that the increased serum urate-level and the increased uric acid excretion in the human could be completely prevented by administering a dose of nicotinamide four times the dose of ethylaminothiadiazole. This antagonism by nicotinamide was not apparent at equal doses of nicotinamide[3].

The increase in purine biosynthesis induced by ethylaminothiadiazole in the non-gouty human provides additional evidence favouring the view that purine biosynthesis is normally governed by a regulatory mechanism. A detailed explanation of the action of this drug should be of considerable value in defining the factors which normally operate to control the rate of purine biosynthesis in the human.

Enzyme Activity in the 'Isolated' Colon

DURING the course of physiological and histological studies on the intestine of the cat, an opportunity was presented for comparing the histochemical activity of the enzymes alkaline phosphatase and non-specific esterase in the colon before and after it had been isolated from the small intestine for varying periods of time following the operation of ileostomy.

In eight cats, the terminal half-inch of the ileum together with the proximal one inch of the colon were removed in one piece, and after the contents of the colon had been expressed the cut ends of the colon and ileum were closed. A special cannula was inserted into the terminal ileum through a separate incision in its wall, and drained into an external receptacle. From the portion of the proximal colon removed at operation two small pieces were excised; one was fixed in cold 80 per cent alcohol for the histochemical demonstration of alkaline phosphatase by means of Kabat and Furth's[1] modification of Gomori's[2] 'cobalt sulphide' technique, and the other was fixed in cold absolute acetone for the histochemical demonstration of non-specific esterase by means of a modification[3] of Gomori's[4] 'Tween' technique, using 'Tween 40' as the substrate.

Table 1

	Est.	(+)	(+)	

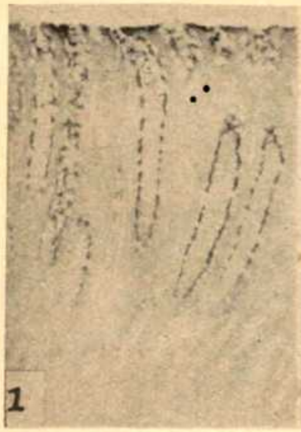
A.P., Alkaline phosphatase; *Est.*, non-specific esterase. The signs (+), +, +(+), ++ indicate the intensity of the enzyme activity.

After periods ranging from 3 to 10 days, the animals were killed, and pieces of tissue were removed from near the sutured end of the proximal colon for histochemical study of the activity of alkaline phosphatase and non-specific esterase, which was then compared with the activity shown in the biopsy specimens.

The histochemical reaction for alkaline phosphatase is particularly intense in the large intestine of the cat, and is of about equal intensity throughout its length[5]. The reaction is present in the intestinal contents, in the surface epithelium and in that of the crypts, extending into the latter for two-thirds or more of their length, then gradually fading in their deeper parts; this reaction occurs at the striated border of the cells of the surface and crypt epithelium and sometimes also in granules in the distal part of the cell cytoplasm. In addition, the reticular fibres around the crypt bases are positive. Non-specific esterase, as demonstrated by the 'Tween' technique, is localized in the cytoplasm of the epithelial cells lining the intestinal surface and approximately the upper one-third of the crypts, but the intestinal contents do not react[6].

Comparison of the enzyme activity in the specimens taken from the proximal colon before and after ileostomy was made by incubating all the sections in the same substrate bath for the same period of time. The reaction for alkaline phosphatase is so intense in the cat's colon that, to make this comparison, a very short incubation period had to be employed: after several trials, it was found that 2 min. was a suitable period to use. In the case of non-specific esterase, a long incubation period is needed with the 'Tween' technique to bring out a reaction; a period of 48 hr. was used, but, even after this time, differences in intensity of reaction were apparent.

The results of the investigation are summarized in Table 1. It is seen that, with the exception of two cases (Nos. 3 and 8), the reaction for alkaline phosphatase actually increased after ileostomy. Following the very short incubation period used, the histochemical reaction was somewhat incomplete, even in this strongly reacting tissue; it first appeared at sites of greatest activity, namely, in the middle and upper parts of many crypts, areas of the surface epithelium and sometimes in the contents within the crypts and intestinal lumen. Any increase in enzyme activity was shown by a heavier deposit of cobalt sulphide in



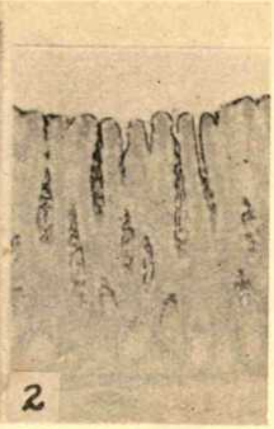


Fig. 1. Proximal colon, cat. Alkaline phosphatase reaction before ileostomy. 2 min. incubation. (× 75)

Fig. 2. Alkaline phosphatase reaction 5 days after ileostomy. The reaction has increased in extent and in intensity. Note shrinkage of the mucous membrane. 2 min. incubation. (× 75)

the reactive areas, and by an extension of the areas of reaction in the surface and crypt epithelium. An extension of the reaction into the deeper parts of the crypts, where the reaction is normally weaker than in the upper parts, was a particularly useful index of increased enzyme activity. Comparison of Fig. 1 with Fig. 2 (sections from No. 5 in Table 1) illustrates the difference in activity encountered before, and five days after, ileostomy.

Regarding non-specific esterase, it will be seen from Table 1 that in no case was there a decrease in enzyme activity after ileostomy ; in four cases there was no obvious change, but in the other four (Nos. 1, 4, 5 and 6) there was actually an increase in activity.

It is concluded that, within the colon of the cat after 'isolation' by means of the operation of ileostomy, there is no diminution in the activity of the enzymes alkaline phosphatase and non-specific esterase, even after five or more days ; on the contrary, the activity tends to increase.

It has been shown experimentally that alkaline phosphatase is secreted by the dog's colon[7]. The present histochemical results indicate that this is true for the cat, since the contents in the intestinal lumen and in the crypts are positive before and after ileostomy. However, the results show that the inflow of ileal contents is not a necessary factor either in maintaining the activity of the enzyme within the lining epithelium or in stimulating its continuous secretion. It is possible, however, that the quantity of alkaline phosphatase *secreted* is less in the 'isolated' colon, and that the increased activity in the epithelium indicates some degree of enzyme storage in the resting colon.

Distribution of Haptoglobins in Native Venezuelans

HAPTOGLOBINS are globulins present in normal human plasma which are capable of combining and carrying hæmoglobin. First detected by Polonovsky and Jayle[1] in 1938, they became the object of detailed studies, mainly by French authors[2]. Smithies[3], in 1955, studying normal human serum by zone electrophoresis in a starch gel supporting medium, showed that it was possible to differentiate three groups easily when a certain amount of hæmoglobin was added to the serum. It was later demonstrated that this polymorphism was based on electrophoretic differences in the haptoglobins[4].

In 1958, Allison, Blumberg and Rees[5] studied the distribution of haptoglobins in English subjects, Spanish Basques and Negroes from Nigeria. By comparing these results with previous studies[6,7] made on Canadian and United States subjects and negroes from Liberia and the Ivory Coast[7], they concluded that the distribution of haptoglobins might well have anthropological significance. Since the Venezuelan population is derived mainly from various Indian racial stocks, different European groups (especially Basques and other Spanish branches) and African Negroid populations, a study of such a population should help prove such an assumption. The present communication gives the first results obtained by studying the distribution of different types of haptoglobins in the native population of Venezuela.

A study was conducted on 208 adult persons, aged 18–50, apparently normal, most of whom were voluntary donors of the Hospital Universitario de Caracas Blood Bank. The majority was from Caracas and the rest came from nearby districts and such distant places as San Cristóbal (Estado Táchira), San Fernando (Estado Apure) and Güiria (Estado Sucre). Since donors are generally male, only 27 female subjects were studied.

Blood was obtained by venipuncture and left clotting for 2–3 hr. Sera not immediately used were kept frozen until the time of use, when enough hæmoglobin solution was added to saturate haptoglobins.

In order to distinguish the various groups of haptoglobins, zone electrophoresis in a starch gel was used, according to Smithies's method[6], with slight modifications which will be described separately. After electrophoretic migration the starch gel slab was divided horizontally into two halves. One of them was stained with amidoschwarz 10*B* and the other with benzidine[8]. By this method it was easy to classify the right type of haptoglobin for each sample, and in order to check this classification those pertaining to one group were again studied together. This also gave a comparative evidence of previously described minor differences in subjects having the same phenotype[6,8,9].

Both the ABO and Rh blood group systems were determined by standard techniques.

The material studied gave a frequency of 27·40 per cent for phenotype 1–1, 17·79 per cent for 2–2 and 54·81 per cent for 2–1. This corresponds to a frequency for gen Hp^1 of 0·54805 and for gen Hp^2 of 0·45195. The χ^2 test for 'goodness of fit' was 0·011. With 1 degree of freedom, P is 0·91.

No relation was found, in analysing our results (Table 1), between haptoglobins and blood groups. This agrees with other authors[10,11].

Table 2 shows the distribution of different types of haptoglobin in the populations hitherto studied, to

Table 1. Distribution of Haptoglobins according to Sex, ABO and Rh Blood Group Systems

Haptoglobin phenotypes	No.	Sex (per cent)		ABO (per cent)				Rh (per cent)	
		Male	Female	O	A	B	AB	+	−
Hp 1–1	57	87·72	12·28	42·10	38·60	12·28	7·02	96·49	3·51

Hybrid :										
Venezuelan (Caracas)	—	208	0	0	57	27·40	114	54·80	37	17·80

which our own results have been added. When an anthropological separation is made, the material investigated by us appears to be the first hybrid population studied.

It appears from this Table that our results are fundamentally different, in many respects, from those obtained by other authors. The frequency obtained for phenotype 1–1 (27·40 per cent) is much higher than that obtained for Caucasoid populations but lower than that of Negroids. This incidence might indicate in what percentage the African race enters into our native population. On the other hand, the frequency of phenotype 2–2 found in the Venezuelan population (17·79 per cent) is much higher than that found in African populations but lower than that of Caucasoids, which might indicate the participation of the European element in our hybrid population. Our results seemingly confirm the anthropological importance of haptoglobin frequency. Since the Indian population has not been studied before it has not been included. It is now being investigated and will be the subject of a further report.

It is of importance that the presence of phenotype 0–0 was not noticed in our material. This phenotype was not originally described by Smithies[6], but its existence was postulated by Allison, Blumberg and ap Rees[5] in their studies of samples from Nigeria, and also by Harris, Robson and Siniscalco[12] in their studies of 107 families. Keeping in mind the high percentage in which the African factor enters into the constitution of the present native population of Venezuela, this negative result is of primary importance since it indicates that the African populations taken to Venezuela in the days of the slave trade may have been biologically different from the present population of Nigeria. If future investigations should confirm the absence of this phenotype in the normal population of Venezuela or any other South American country, these results would confirm those of Sutton *et al.*, who apparently found no individual differences from the three phenotypes described by Smithies[3,6]. This is contrary to the idea of Allison *et al.* that the series of Sutton *et al.* possibly included subjects of group 0–0 in group 1–1. If this explanation is rejected, one would have to conclude that both the samples from Nigeria examined by Allison *et al.* and the material studied by Harris *et al.* comprised persons who for some subclinical process (hæmolytic anæmia, pernicious anæmia, hepatitis, etc.) showed a temporary absence of haptoglobins (acquired ahaptoglobinæmia) instead of a permanent absence (congenital ahaptoglobinæmia). Careful analysis of the results of Allison *et al.* (Table 2) seems to show that the great proportion of phenotype 0–0 found reduces the frequency of phenotype 2–1. This phenotype, with the most haptoglobins, is more easily made to disappear by any of the pathological processes mentioned above.

We are indebted to Mr. Alfredo Pansini for helping in the translation of the Spanish text.

Pathways and the Physiological Site of Anserine Formation

It is clear from *in vivo*[1] and *in vitro*[2] studies that vertebrate skeletal muscle contains an enzyme that can condense 1-methylhistidine and β-alanine (in the presence of magnesium and adenosine triphosphate) to yield anserine. However, two other paths of anserine biosynthesis have been suggested[1]: β-alanyl transfer from carnosine to methylhistidine, and the direct methylation of carnosine. The former possibility has not yet been investigated. The latter alternative is the subject of the present communication. While methyl-labelled methionine was shown to supply effectively the methyl group of anserine[3,4] *in vivo* it was not evident from such experiments whether N-methylation occurred at the histidine or carnosine stage, nor was the physiological site of anserine formation revealed.

The investigations of Cantoni[5] and of Stekol, Anderson and Weiss[6] have disclosed that S-adenosylmethionine is the direct methyl group donor in the synthesis of creatine (from guanidoacetic acid) and choline (from dimethylaminoethanol) in the liver. It was of interest, accordingly, to determine whether the activated methionine derivative could likewise transfer its methyl radical to histidine or carnosine in the presence of tissue preparations. For this purpose we prepared S-adenosyl-L-methionine, labelled in its methyl with carbon-14, by a biosynthetic method[6]. An extract of chick pectoral muscle[2], found to be active in the biosynthesis of carnosine and anserine, was tested under conditions similar to those employed for the synthesis of choline and creatine by liver homogenates[6], except that our substrate concentrations were somewhat higher. Following a 2-hr. incubation at 37° C. (Fig. 1), the protein was precipitated by addition of 1·5 ml. of ethanol to the reaction mixture, and heating to boiling. After centrifugation, aliquots of the supernatant solution were subjected to paper chromatographic analysis (Whatman No. 1). The solvent was *t*-butanol–formic acid–water (70 : 15 : 15). After 24 hr. the methylhistidine and anserine regions were about 3–5 cm. from the origin, while the excess isotopic methionine and its adenosyl derivative (actually decomposed, apparently to S-methyladenosine) migrated much farther along the paper. The desired radioactive areas were cut out and measured in a windowless gas-flow Geiger counter. All values were corrected for the small background radioactivities found in parallel experiments with inactivated enzyme preparations. Fig. 1 shows that even in the absence of non-labelled substrate about 1 per cent of the carbon-14 of adenosylmethionine was used for transmethylation. This result can very likely be attributed to the considerable concentration of carnosine in the muscle extract employed. With the addition of excess histidine, the utilization of adenosylmethionine reached 2 per cent; while a value of 3 per cent was attained when the concentration of added carnosine was 9 μmoles/ml. It can be seen that methionine itself was ineffective for methylation. Apparently this amino-acid was not activated under the conditions employed.

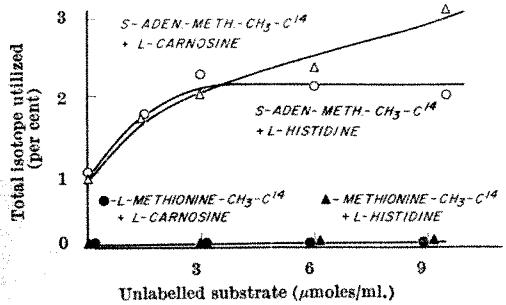

Fig. 1. Comparison of methione and its adenosyl derivative as methyl donors for histidine and carnosine. The incubation mixture (0·5 ml. final volume, *p*H 7·4) contained 0·3 ml. of centrifuged 1 : 4 muscle homogenate, histidine or carnosine in varying concentrations, and either L-methionine-CH_3-^{14}C or S-adenosyl-L-methionine-CH_3-^{14}C (each with an activity of 0·1 mc./m.mole) at a level of 3·5 μmoles/ml.

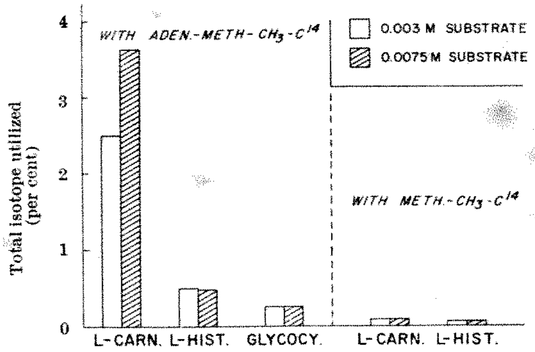

Fig. 2. Relative rates of methylation of histidine and carnosine by ethanol-precipitated protein fraction of muscle. The incubation mixture (0·5 ml.) contained 8 mgm. protein and 3·5 μmoles labelled methylating agents per ml., in addition to histidine or carnosine. The conditions of incubation and of subsequent analysis were those of Fig. 1 except that *n*-butanol–ethanol–water (4 : 1 : 1) was used for the chromatographic isolation of creatine (found 2–4 cm. from the origin after 24 hr.)

Similar results were obtained (Fig. 2) when a protein fraction of chick pectoral muscle extract, precipitated between 20–60 per cent ethanol concentration[7], was used as source of enzyme. The rate of methylation of carnosine relative to that of histidine is accentuated in Fig. 2, as compared with the corresponding ratio with the crude muscle extract. Here again, when free isotopic methionine was used, no significant radioactivity was found in the methylhistidine or anserine regions of the chromatograms. Our highest values obtained with muscle are comparable in magnitude to those for creatine and choline synthesis with liver homogenates (about 4–5 per cent utilization of adenosylmethionine in 2 hr.)[6].

The results with muscle enzyme were confirmed by the use of isotopic histidine and carnosine, together with unlabelled S-adenosylethionine. The availability of these compounds and the ease of chromatographic separation of ethylated products (as compared with methylated) from the parent histidine and carnosine suggested the experiment of Table 1. Following incubation, chromatography was performed with 2 : 1 pyridine/water for 24 hr. Histidine and carnosine migrated 19–21 cm., while ethylhistidine and ethylcarnosine were located at 24–26 and 25–27 cm., respectively, from the origin. (Synthetic 1-ethylhistidine[7] was used as a reference standard.) Because of the very soft β-rays of tritium it was necessary to elute the ethylcarnosine region from the paper, and to evaporate the eluate on a planchet, in order to measure accurately the radioactivity (in the gas-flow counter). Table 1 shows that, as in the methylation experiments, carnosine was N-alkylated more readily than histidine.

In experiments performed with chick liver homogenates we could not detect significant utilization of labelled adenosylmethionine for transmethylation of

Table 1. ADENOSYLETHIONINE AS AN ALKYLATING AGENT FOR HISTIDINE AND CARNOSINE

The conditions were those of Fig. 2, except that the incubation mixture contained 2 μmoles/ml. of non-isotopic S-adenosyl-L-ethionine and 3·5 μmoles/ml. of either DL-histidine-2-^{14}C (0·5 mc./m.mole) or L-carnosine-^{3}H (about 1 mc./m.mole). The latter compound was prepared by tritium-recoil labelling (ref. 8), and purified by paper chromatography with 2 : 1 pyridine–water

Isotopic substrate	Percentage of total radioactivity utilized for transethylation
L-Histidine-2-^{14}C	0·75
L-Carnosine-^{3}H	2·15

carnosine or histidine. It had been previously found that liver slices were incapable of synthesizing carnosine and anserine from their constituent amino-acids[9]. Hence it appears likely that skeletal muscle is the tissue concerned with both peptide bond formation and the methylation process. Although our results indicate that carnosine is methylated to a greater extent than is histidine, both *in vivo* and *in vitro* experiments show that methylhistidine condenses more readily with β-alanine than does histidine. Thus it is difficult to decide which path is the major one for anserine formation in the animal.

Liver is commonly regarded as the organ concerned with the methylation of guanidoacetic acid. However, since creatine is abundant in muscle but not in liver, it seemed of interest to determine whether muscle tissue could also form creatine from its precursor. Fig. 2 shows that this process was negligible in circumstances which promoted relatively rapid methylation of carnosine by adenosylmethionine. If it is assumed that the conditions employed for the detection of creatine synthesis were optimal, the results suggest that the transmethylating system of muscle is rather restricted in its specificity, and may function primarily in the formation of anserine.

This work was supported by a grant-in-aid of the Muscular Dystrophy Associations of America.

We wish to thank Dr. J. A. Stekol of the Institute for Cancer Research, Philadelphia, and Dr. G. L. Cantoni, National Institute of Mental Health, Bethesda, for kindly supplying samples of adenosylmethionine and -ethionine, together with helpful information.

A New Hæmagglutinating Substance in the Gm System, Anti-Gm

A SYSTEM of inherited serum groups has been described by Grubb and Laurell[1]. Sera from certain patients with rheumatoid arthritis agglutinated Rh-positive red cells which had been coated with selected incomplete anti-D. The agglutination was inhibited by sera from about 60 per cent of normal individuals, who were said to be Gm(a+) because the inhibiting substance was located in the gamma-globulin fraction of serum. This substance was inheritable, determined by the gene *Gm*^{a}, which expressed itself in single or double dose. The corresponding allele was called *Gm*.

Among 320 unrelated Norwegians, the following frequencies were found[2]:

Phenotypes	Genes
Gm(a+) 194 (60·63 per cent)	Gene *Gm*^{a} 0·3726
Gm(a−) 126 (39·37 per cent)	Gene *Gm* 0·6274

We investigated sera from 65 patients with rheumatoid arthritis presenting a positive Waaler-Rose's test, and found one serum (J.K.) which contained a substance antithetic to anti-Gm^a.

Group O red cells of genotype C+ D+ E+ c+ were coated with a selected sample of incomplete anti-D. The anti-D serum was of type Gm(a−). After washing, the cells were agglutinated by serum J.K. diluted up to 1 : 256, giving a score[3] of 29. The reactions were run on a slide as previously described[2], and the degree of agglutination was read microscopically. The agglutination was inhibited by pooled human gamma-globulin and by 97 (81·5 per cent) of 119 sera from unrelated individuals. For typing, the rheumatoid serum was set up in serial twofold dilutions. To one drop of each dilution one drop of the serum to be tested (diluted 1 : 8) and one drop of a 0·3 per cent suspension of coated red cells were added. Most of the sera (81·5 per cent) inhibited the agglutinating substance of serum J.K., as shown by reduction of agglutination scores to between 0 and 8. In contrast, normal sera giving scores of 21–29 were considered non-inhibiting. Sera obtained from venous blood samples always gave clear-cut reactions, whereas intermediate reactions (score 10–15) were met with in 4 of the samples of capillary blood from children in a family material.

The specificity of the agglutinating substance in serum J.K. was ascertained by the following observations:

1. The investigation of sera from 119 unrelated individuals (including the parents in the family material) gave the following result:

	Inhibition of agglutination	No inhibition of agglutination
Gm(a+) 73	51	22
Gm(a−) 46	46	0

The probability that the hæmagglutinating substance in serum J.K. is unrelated to the Gm system is $p < 0{\cdot}0001$ ($\chi^2 = 16{\cdot}99$ for 1 degree of freedom).

Among the 73 Gm(a+) individuals, 56 were probably heterozygous (*Gm*^{a}/*Gm*) and 17 homozygous (*Gm*^{a}/*Gm*^{a}), as calculated from the gene frequencies. Actually, 51 of the sera inhibited the agglutinating substance in serum J.K., while 22 sera did not. The difference between the observed and expected values is not significant ($\chi^2 = 1{\cdot}92$ for 1 degree of freedom).

2. Sera from the members of 25 families with 66 children were studied.

Among the children, 26 were of type Gm(a−). Sera from 25 of them inhibited the agglutinating substance in serum J.K., while one serum showed an intermediate reaction. If one assumes that the serum giving an intermediate reaction really is inhibiting, the probability that this distribution is merely due to chance is $P = 0{\cdot}025$ (Fisher's exact method).

Based on Gm^a type determinations, the genotype *Gm*^{a}/*Gm* could be proved in 24 individuals. Of these sera, 22 inhibited the agglutinating substance in serum J.K., while 2 showed intermediate reactions. If again the assumption is made that the two sera really are inhibiting, the probability that this distribution is due to chance is $P = 0{\cdot}043$ (Fisher's exact method).

When all children (4 or more) in matings of type Gm(a+) × Gm(a−) were Gm(a+), the Gm(a+) parent was expected to be of genotype *Gm*^{a}/*Gm*^{a}. Similarly, when 4 or more Gm(a+) children were found in a mating of type Gm(a+) × Gm(a+), one of them was expected to be of genotype *Gm*^{a}/*Gm*^{a}.

On this basis, 6 individuals in the family material were expected to be of genotype *Gm^a/Gm^a*. Sera from 5 of them did not inhibit the agglutinating substance in serum J.K., while one serum did so. The probability that this is merely due to chance is $P = 0{\cdot}05$ (Fisher's exact method).

In seven families, one or more children were thought to be of genotype *Gm^a/Gm^a* because their sera did not inhibit the agglutinating substance in serum J.K. In all these matings, both parents were of type Gm(a+). The probability that this is due only to chance is $P = 0{\cdot}00091$.

The fourth intermediate reaction was observed in a child of type Gm(a+), whose genotype could not be predicted.

From these observations, it is concluded that the agglutinating substance in serum J.K. reveals the substance determined by the gene *Gm*. The serum is therefore called anti-Gm in accordance with previous designations[2] of sera related to the Gm system. The term anti-Gm does not imply that the agglutinating substance is necessarily the result of previous immunization; it is simply a designation based on the observation that the agglutinating substance in serum J.K. reacts with the Gm substance.

Exploratory Physicochemical Studies on the Sense of Taste

IN the past, many chemists have tried to account for the tastes of substances in terms of their chemical structures. Although limited correlations have been found, no rigid, widely applicable generalization has evolved. In view of the poor success in this direction, it is apparent that the relationship is very complex. With the belief that taste, as well as other physiological responses, will be understood eventually in terms of the molecular properties of substances, a deliberate search was begun in this laboratory to identify these properties for the sense of taste.

Our general plan of attack has been twofold[1]. One approach is to postulate a mechanism by which the sapid substance can trigger a nerve impulse to the brain to be recognized as a taste sensation and then to examine the molecular properties related to this mechanism. The second approach is to search for correlations between taste and molecular properties with the hope that one or more will be found to give a clue to the mechanism of taste stimulation. Space does not permit an elaboration of the reasoning followed in choosing the properties to be measured. Furthermore, since no positive generalizations have been discovered, it is sufficient to report only the experimental results.

A specific group of compounds was selected the tastes of which range from tasteless to 4,000 times as sweet as sucrose. The relative sweetnesses were determined by a taste panel under the supervision of Drs. Frank Pilgrim and Howard Schutz of the Quartermaster Food and Container Institute, U.S. Army, Chicago. Several isomeric pairs were chosen, including optical isomers, in order to have a critical test for any relationships discovered. Attention was confined to the sweet taste in order to keep the number of variables to a minimum and because structural modifications can be made to elicit a wide variation in intensity of response.

III	0·269	0·732	0·0585	0·0244	0·494	0·0041
IV	0·186	0·745	0·0403	0·0125	0·275	0·0021

In the search for correlations between taste and molecular properties, a few properties which could affect the taste of a compound were studied first. Although some of these properties had been measured by previous investigators, the present work differs in that all measurements were made by the same group of investigators on compounds the tastes of which had been evaluated by the same panel. The results are given in Table 1.

Our second approach for finding a clue to the molecular properties responsible for characteristic tastes is to consider mechanisms by which sapid substances might trigger nerve impulses to the brain. Table 2 contains the results of a search for a correlation between the sweet taste and adsorption on a certain surface. Charcoal was used first in order to work out the experimental procedure. The hair was that of a child, washed in a nonionic detergent, and air-dried at room temperature. Two types of tongue tissue were used in unreported experiments but the results were not reproducible. The results in Table 2 fit the Freundlich equation :

$$x = \alpha c^{1/n}$$

where x represents millimoles of adsorbate held per unit weight of adsorbent ; c the concentration of adsorbate remaining unadsorbed at equilibrium in moles/litre ; α and n are constants ; while, in Table 2, W is the weight of substance adsorbed at the concentration of 0·01 gm./100 gm. solution.

Experiments were done to detect any special interaction between sweet compounds and certain biological substances. The results from one type of experiment are given in Table 3, from which no significant difference is observed between a sweet compound and its tasteless isomer. The numbers I and II refer to the compounds in Table 2. Other experiments were conducted to learn whether or not certain components common to enzyme systems are involved in taste chemireception. Thus, sweet solutions of 2-methoxy-5-nitroaniline and salty sodium chloride solutions were tasted in a helium atmosphere. Other than a sort of warming sensation, no significant difference in taste from that in air was observed. Sweet solutions of 2-methoxy-5-nitroaniline were tasted when diluted with solutions of magnesium chloride, manganous chloride, or water. The solutions containing magnesium or manganous ions were bitter and sweet, and magnesium ion could not be distinguished from manganous ion by taste. Then, to see whether or not the sapid substance interacts directly with an enzyme, solutions of a sweet compound were tasted in the presence of certain enzyme inhibitors. For example, several aliquots of a sweet solution of 2-methoxy-5-nitroaniline were diluted separately with water, or with solutions of sodium azide, potassium fluoride, sodium iodoacetate, or sodium cyanide. These solutions were mixed and tasted in random order several times without their identity being known to the taster (L. N. F.). Azide enhanced the sweetness of the nitroaniline, but fluoride and iodoacetate diminished the sweetness a very small amount, iodoacetate gave an iodine flavour, and cyanide was very bitter, outweighing the sweet taste. However, none of these recognized enzyme inhibitors obliterated the sweet taste irreversibly. This fact suggests that the taste receptor surface is not that of an enzyme.

Thus several physical properties which conceivably could be factors determining the tastes of substances have been measured. Also, various possible mechanisms for stimulus-receptor interactions have been examined. Although no positive generalizations have been found, and these experiments have been exploratory, the results serve as guides for future work in pursuing the identity of the molecular proper-

ties responsible for the characteristic tastes of substances. It is to be realized that the nature of the stimulus-receptor interaction is unknown and these exploratory-type experiments constitute an attempt to find a clue on a gross level.

This work was undertaken in co-operation with the Quartermaster Food and Container Institute for the Armed Forces, Quartermaster Research and Engineering Command, U.S. Army.

Energy Compensation in the Crabtree Effect with Ehrlich Ascites Carcinoma Cells

RECENTLY, Quastel and Bickis[1] published a very interesting and stimulating article concerning the energy relationships in several intact cell types, including the Ehrlich ascites carcinoma cell. They determined the ratio of lactate produced to the difference between oxygen consumed in the cell system with and without added glucose (average value 5·8). The assumption was made that the amount of adenosine triphosphate produced in the two systems was the same. They reasoned that if the total production of energy remained constant in the two cell systems, the ratio phosphorus/oxygen would be about 3.

Table 1. ENERGY RELATIONSHIP BETWEEN GLYCOLYSIS AND THE DEPRESSION OF RESPIRATION OF THE CRABTREE EFFECT

Compound (μM per ml. cells)	With glucose	Endogenous	$\frac{\text{Lactate}}{\Delta\ \text{Oxygen}}$
Oxygen utilized	16·3	27·7	
Lactate accumulated	57·2	—	5·0
Adenosine triphosphate present	1·60	1·65	(P : O = 2·5)

Incubation system: 12·4 volume per cent of tumour cells in phosphate Locke's solution, pH 7·4; 30° C. for 15 min.; glucose 51·7 μM per ml. cells.

We recently published observations[2] on the Ehrlich ascites cells which show that the adenosine triphosphate content of the endogenous- and the glucose-containing cell is the same, except for an initial brief period of equilibration. This means that glycolysis does produce an amount of energy equivalent to the energy lost by the decreased oxygen consumption, provided the utilization of adenosine triphosphate remains constant. Furthermore, Table 1 shows that the accumulation of lactate could nearly account for the decrease in oxygen consumption in terms of production of adenosine triphosphate, assuming a phosphorus/oxygen ratio of approximately 3 (2·5) and glycolytic production of 2 molecules of adenosine triphosphate per glucose molecules. These results are in good agreement with Quastel and Bickis's hypothesis.

PATHOLOGY

Homologous Species Neoplastic Antibodies

Prehn and Main[1], in a review of the subject, state that the demonstration of circulating cytotoxins is much simpler when heterologous tissue transplants are used as antigens than when homologous tissues are used. Schrek and Preston[2], using the Bagg rat lymphosarcoma in Sprague–Dawley rats, report the successful demonstration of serum cytotoxins in the rats (25 per cent of the total) in which the tumour had regressed.

The present communication deals with a limited investigation on the response of a human male to two cultures of human adenocarcinoma, arising in two different individuals.

Cultures of the neoplastic tissue were used instead of tissue homogenates in an effort to obtain as pure a cellular antigen as possible. Fresh cultures were used instead of known cultures of long standing because of the reported tendencies of long-term culture lines to become alike in antigenic characteristics[3].

(1) A healthy white male, blood type O,Rh-positive, was used as the antibody producer.

(2) Fragments of three adenocarcinomas were obtained from males at primary surgical removal and cultured by Puck's methods until pure cultures of the neoplastic cells were obtained. These separate cultures were labelled *C.P.*, *A.N.* and *C.G.*

(3) A portion of the living culture *C.P.*, estimated to be of the order of 10,000,000 cells, was suspended in salt solution and injected subcutaneously in the upper arm. The implant increased in size for ten days with marked local redness of the skin and moderate tenderness. By the fourteenth day the implant had decreased in size by 50 per cent. There was no systemic effect noted.

On the eighteenth day a similar amount of culture *C.P.* was introduced as before in a new location. The local reaction was immediate but decreased by half by the sixth day after implantation.

A third implantation of like amount was accompanied by local reaction more violent than the preceding two and by mild general systemic reaction lasting 24 hr. Disappearance of the local mass was almost complete at the end of the sixth day.

Seven days after the third implantation of *C.P.*-cultured cells, blood was withdrawn, the serum separated and an amount of this serum, equal to 1/400 of the total nutrient solution, was added to the nutrient solution consisting of 40 per cent adjunct nutrient solution. The nutrient solution, minus the immune serum addition, was the one used previously on all cell cultures and had proved adequate for growth.

A culture each of *C.P.*, *A.N.* and *C.G.* was drained of nutrient solution, washed and the nutrient solution containing the immune serum introduced.

The cultures were examined at 6, 12 and 24 hr. Culture *C.P.* at the end of 6 hr. showed nuclear degeneration, the nucleus in most cases forming an amorphous halo. There was marked rounding and shrinking of the cells. Subcultures taken at this time failed to grow, as did those made at 12 and 24 hr. Cultures *A.N.* and *C.G.* showed no effect of the immune serum, and both were successfully subcultured.

An identical series of implantations on the same individual were made except that in the second case cultures of *A.N.* were used as antigen. There were no major differences in reaction as compared to the first run.

The immune serum, used in the same concentration as before, now produced nuclear degeneration and death of cells in both culture *C.P.* and *A.N.* Culture *C.G.* remained unaffected by the immune serum–nutrient mixture, both morphologically and by successful subculture.

Heating the immune serum for 40 min. at 56° C. destroyed its cytotoxic activity, which was restored on the addition of fresh non-immune human serum.

PSYCHOLOGY

The Water–Salt Receptor and Preference in the Rat

Zotterman[1] and his co-workers have reported that in the rat and in man the taste of water consists in a reduction of the spontaneous firing of the salt receptors. According to Deutsch's theory[2] of need and reward, satiation of thirst is due to the reception of a certain quantity of messages signalling the ingestion of water. The quantity of fluid ingested would be proportionate to the number of signals generated by it. It follows that as a hypotonic solution of saline reduces the spontaneous firing of salt receptors less than the same volume of water, it would generate less of a 'water signal'. A rat should therefore drink more saline solution even when water is present. This has already been noted by workers such as Richter[3] and Bare[4] and ascribed to a preference for weak saline solutions. But if the above hypothesis is correct, the ingestion of saline by the rat is not due to a preference but to the fact that it has been given 'diluted water', if we can put it that way.

On this theory a certain amount of reward is also proportionate to the total quantity of messages signalling the ingestion of a goal substance. Therefore if this hypothesis is correct, we should predict the opposite 'preference' in a situation where the intake of each fluid is restricted to a certain volume. Thus rats, when they are forced to choose between equal amount of water and saline in a maze, should learn to run to the water arm, as a given volume of saline generates fewer signals than the same volume of water. Accordingly, two experiments were carried out.

The first was carried out in a T-maze. Nine rats, aged 4 months, were given 2 hr. of *ad lib.* water drinking a day and *ad lib.* food except during maze running. Each animal was given 15 runs a day in the T-maze under 20 hr. of water deprivation to rewards of water in one arm and 0·5 per cent saline in the other, four animals receiving water in the right arm and five in the left. The average number of runs to water over the 6 days was 56, and to the saline, 34 (significant at the 0·001 level of probability).

In the second experiment, a group of 10 rats was put on the same schedule as those above. They were presented with two water bottles for half an hour when they were 20 hr. thirsty, one containing 0·5 per cent saline, the other water. The position of the bottles varied. The experiment confirmed that during eight days the average amount of saline drunk was 59 c.c. as against 36 c.c. (significant at the 0·01 level of probability).

The experiment therefore confirms the prediction and also casts considerable doubt on the conventional ways of measuring preference. It is hoped to investigate further the behaviour of species which lack this gustatory arrangement, and other parameters of the ingestion of saline by the rat. Further, the spontaneous rate of firing of the saline receptors should vary with the degree of salt depletion. This should in its turn reduce the level of water intake. Whether such a simple control mechanism does in fact govern the ingestion of water in relation to salt suggests a further line of investigation.

PALÆONTOLOGY

Precambrian Coelenterata from Australia, Africa and England

Extensive collecting has been carried out during the past two years by private collectors, the South Australian Museum, the University of Adelaide and Mr. R. C. Sprigg and associates, in flaggy quartzites near the base of the Cambrian at the old Ediacara mines, 280 miles due north of Adelaide, South Australia. Sprigg[1] found and described as jellyfishes fossil remains of soft-bodied animals from this locality. The study of the abundant new material[2], which comprises about 800 specimens, has led to the following results. (1) The fauna consists not only of the forms described by Sprigg as scyphozoan and hydrozoan medusæ, but also of Anthozoa representing the Octocorallia, of Annelida[3], and of at least two entirely new types of soft-bodied invertebrates[2,3]. (2) Certainly one and possibly more elements of this fauna belong to genera described from the Kuibis Quartzite of the Nama System in South Africa, and one genus recently described[4] from the Precambrian of Charnwood Forest, Leicestershire, also occurs at Ediacara. (3) New stratigraphical and palæontological evidence indicates Late Precambrian age of the Ediacara fauna.

The most striking and unexpected discovery is the common occurrence of representatives of the South African genus *Rangea* Gürich[5] in the Ediacara fauna. About forty specimens are now known, and one new species has been described, though further finds may indicate the presence of more species in this material. It is preserved in different forms, which can be interpreted as different aspects and stages of preservation of the soft body. Some specimens show a long stalk attached to the leaf-shaped main body. This has either a median field or a median zig-zag furrow, and lateral furrows branching out from it. A spicular structure is seen occasionally in the body and stalk. The details of these structures, which will be described elsewhere[2], clearly establish a close relationship between *Rangea* and the living Pennatulacea. In.

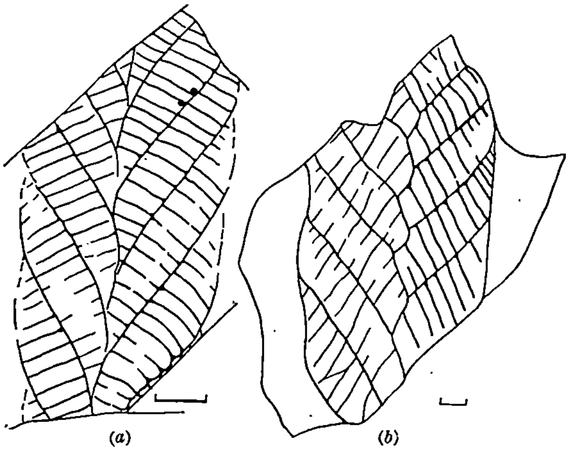

Fig. 1. *a*, Portion of the 'frond' of *Charnia masoni* Ford from the Precambrian of Charnwood Forest, Leicestershire (copy of portion of Ford's Pl. 13, Fig. 3). *b*, *Charnia* sp. from Ediacara, South Australia. S. Aust. Mus. No. P12897. Length of each scale 1 cm.

this order of the Anthozoa the polyps sit either on the rhachis or on discrete leaf-like lateral extensions; *Rangea* may be intermediate between these two groups as the lateral 'branches' are not free as in *Pennatula* but form a single leaf. The genus *Pteridinium* Gürich, which is common in the Kuibis Quartzite, is at present represented in the South Australian fauna only by two poorly preserved specimens. As Richter has observed, it belongs to the same family as *Rangea*; but this cannot be placed in the Gorgonacea with which it has no distinctive features in common, but belongs to the Pennatulacea. These had been previously reported from the Tertiary, Cretaceous and Jurassic and, with some doubt, from the Silurian and Ordovician.

The recent discovery[4] of fossils in the Charnian of Charnwood Forest is of extraordinary interest in this connexion. A single specimen from Ediacara, with the proximal and distal ends broken off (Fig. 1), was classified as *Rangea*(?) sp. before the description of *Charnia* Ford became available. There is no doubt that the two fossils are congeneric; but the South Australian specimen is almost twice the size of the holotype of *Charnia masoni* Ford. The author left the affinities of this fossil in doubt but concluded that it "may most rationally be interpreted as an algal frond. . . . The only likely alternative is that they [that is, *Charnia* and the associated *Charniodiscus*] represent a primitive coelenterate of unknown affinities". *Charnia* is sufficiently close to *Rangea* to be considered as related to the Pennatulacea.

This raises the question of the nature of *Charniodiscus*. Ford has suggested a possible relationship with *Charnia*, with the medusoid disk-like fossil forming the base of the stalk to which the frond-like *Charnia* is attached at the other end. A similar relationship between some of the medusoid fossils from Ediacara from which stalk-like bands emerge and the stalked *Rangea* has been considered, but the two have not yet been found actually joined in one specimen. The presence of a disk-shaped base would distinguish *Rangea* and *Charnia* from all living Pennatulacea in which the end of the stalk is merely club-shaped; but in my opinion it would not exclude close relationship. The presence of a medusa-like base which would correspond to the primary axial polyp of a Pennatulacean could lead to phylogenetic speculations about the still obscure relationships of Scyphozoa and Anthozoa. Such speculation would be premature; but it should be kept in mind when the medusoid Precambrian fossils are re-examined.

The Ediacara fauna is placed in the Late Precambrian for the following reasons.[3] It is found 100–200 ft. below the top of a widespread thick quartzite formation (Pound Quartzite) which is conformably overlain by about 500 ft. of limestones with *Archaeocyatha* and brachiopods in the uppermost beds. This assemblage No. 2 of Daily[6] is widespread in South Australia and can be confidently placed low in the Lower Cambrian. Boulders of Archæocyatha limestones with this and successive assemblages Nos. 3 and 4 occur below shales with Late Lower Cambrian protolenids and *Redlichia* on Kangaroo Island. The Ediacara fauna, taken from a horizon below an early Lower Cambrian fauna, is unlike any known Cambrian fossil assemblage. It is therefore correctly assigned to the Late Precambrian. The same age can now be suggested on palæontological grounds for the Kuibis Quartzite of the Nama Group and for the fossiliferous strata of the Charnian.

CHEMISTRY

Some Alkyl-Aryl Sodium Sulphonates as Standard Substances in Detergent Chemistry

In the course of work on the behaviour of commercial detergents of the anionic type, we needed some standard substances with which to compare the commercial products. The sodium sulphonates of the straight-chain substituted benzene hydrocarbons appeared to be likely compounds. The required hydrocarbons from butyl benzene to tetradecyl benzene were synthesized from the fatty acids with even numbers of carbon atoms. The branched-chain compound α-dimethyldecyl benzene was also synthesized. From the hydrocarbons the sodium sulphonates were prepared and purified. The behaviour of these compounds in solution was studied by means of the methylene blue method of Longwell and Maniece[1] and by paper chromatography.

Methylene blue tests on pure sodium sulphonates of the hydrocarbons. Standard solutions of the pure sodium sulphonates of the hydrocarbons were prepared by weighing known amounts of the pure dry substances and dissolving in water to standard volumes. There is a decrease in solubility with increasing chain-length, and special care is required to obtain solutions of the higher members at a suitable concentration. As an example, the solubility of sodium-tetradecylbenzenesulphonate is 6·5 parts per million at 20° C. Aliquots of these solutions were examined by the methylene blue method, and the optical densities of the resulting coloured chloroform extracts were recorded. After allowing for reagent blanks, which were run with each experiment, plots were made of optical density against concentration and from the graphs so obtained Table 1 was derived. From column 4 of Table 1 it is seen that optical

Table 1

Substance	Molecular weight	Value of optical density 200 μgm. of sulphonate	Optical density × molecular weight	
n-Tetradecylbenzene-sulphonate	376	0·935	352	Average value 347
n-Dodecylbenzene-sulphonate	348	1·010	351	
n-Decylbenzene-sulphonate	320	1·075	344	
n-Octylbenzene-sulphonate	292	1·166	340	
n-Hexylbenzene-sulphonate	264	1·138	300	86% of av.
n-Butylbenzene-sulphonate	236	0·106	22	6% ,,
α-Dimethyldecyl-benzenesulphonate	346	0·926	320	93% ,,
Alkylbenzenesulphonate of commerce	356	0·926	330	96% ,,
'Manoxol O.T.'	444	0·780	346	100% ,,

density multiplied by the molecular weight is approximately a constant for the members of the series from *n*-octylbenzene upwards. This is a useful check on the molecular weight of an unknown compound of similar composition. Figures for α-dimethyldecylbenzene sodium sulphonate, the alkylbenzene sodium sulphonate of commerce and for manoxol (sodium-dioctylsulphosuccinate) are included for purposes of comparison. The sodium sulphonates below butyl benzene in the series give no colour under the conditions of the Longwell–Maniece test.

Paper chromatography of some alkyl-aryl sodium sulphonates. Commercial detergents of the alkyl-aryl sulphonate type are difficult to study by paper chromatography, and special methods such as that of F. Franks[2] have been devised for their examination. The difficulties appear to be due to their detergent properties which cause them to remove other substances, including other detergents, from the paper and to carry them forward with their own movement. These remarks also apply to α-dimethyldecylbenzene-sodium sulphonate and to detergents of the 'Teepol' type. With the straight-chain alkyl-aryl sulphonates there are no such effects and chromatography proceeds normally. Values of R_F for four such compounds in various mixtures of alcohol and water are given in Table 2. Whatman No. 4 paper was used and the spots were shown up with a solution of rhodamine 6*B* used as a spray at a concentration of 0·05 per cent w/v.

Table 2. R_F VALUES

Labelling of Radiographic Contrast Media with Iodine-131

THE rapid development and general acceptance of contrast media represents one of the outstanding successes of diagnostic röntgenology. Roentgen contrast media are generally di- or tri-iodo derivatives of benzene or pyridine, containing further substituents influencing solubility. The most widely used contrast compounds are 3,5-diiodo-4-pyridon-N-acetic acid as its diethanolamine salt ('Iodopyracet', 'Diodrast', 'Diodone', 'Ioduron', etc.), and N-methyl-3,5-diiodo-chelidamate as its disodium salt ('Neo-Iopax', 'Iodoxyl', 'Uropac', etc.). A new compound of the urotropic class is sodium-3-acetyl-amino-2,4,6-tri-iodobenzoate known as 'Triopac', 'Urokon', 'Triumbren' and diacetylamino-2,4,6-triiodobenzoic acid, the methylglucamate of which is known as 'Urografin'. The hepatotropic contrast media are represented by N,N′-adipyl-*bis*(3-amino-2,4,6-triiodo)-benzoic acid as methylglucamate ('Biligrafin' or 'Cholografin') and 2-ethyl-3-(3′-amino-2,4,6-triiodophenyl)-propionic acid ('Cistobil', 'Telepaque').

The application of these contrast media for diagnostic purposes gives only a static picture. Pathological changes are diagnosed on the basis of permanent differences in the morphological picture. It is not generally possible to gain information on the functional state of the organs by these means.

The labelling of contrast compounds with iodine-131 opens the possibility of investigating the functional state of the organs by measuring the amount of the compound applied and excreted and its concentration. Indicator diagnosis with the aid of labelled contrast media allows the registration and analysis of the dynamics of processes, and therefore combines both possibilities.

In this communication a method for labelling the more important contrast media with iodine-131 is presented; these are 3,5-diiodo-4-pyridon-N-acetic acid ('Ioduron', 'Diodon'), 3-acetylamino-2,4,6-tri-iodobenzoic acid ('Triopac', 'Triumbren'), N,N′-adipyl-*bis*(3-amino-2,4,6-triiodo)-benzoic acid ('Biligrafin') and 3,5-diacetylamino-2,4,6-triiodobenzoic acid ('Urografin'). An exchange reaction method was used. The use of labelled contrast media ('Triopac') for determining the vitality of bone tissue will be described elsewhere.

Sodium-3-acetylamino-2,4,6-triiodobenzoate-^{131}I, the preparation used, was 'Triopac-400' (Cilag A.G., Schaffhausen, Switzerland) or 'Triumbren' (Spofa, Prague); 2 ml. of the solution contains 1·292 gm. of the sodium salt.

To 2 ml. of 'Triopac-400' solution were added 8 ml. acetate buffer solution *p*H 5, 1 ml. potassium iodide carrier solution (20 mgm. in 100 ml. water) and 4 ml. potassium iodide-131 solution with a radioactivity of 9 mc. The mixture was heated under reflux on the water-bath for 12 hr. The solution was then allowed to cool to room temperature and free 3-acetylamino-2,4,6-triiodobenzoic acid precipitated by addition of concentrated phosphoric acid to *p*H 1. The precipitate was filtered by suction and washed with cold water until the volume of the filtrate was exactly 32 ml. The loss of radioactivity amounted to 1·5 per cent. The precipitate was dissolved in a slight excess of ammonia and the precipitation repeated twice (yield, 1·12 gm. of the free acid (89 per cent) and 90 per cent of the original radioactivity). The purity of the 3-acetylamino-

2,4,6-triiodobenzoic acid was controlled by chromatography in butanol/ammonia/water (50 : 5 : 45) on Whatman No. 3 paper. The acid was detected by radioactivity measurement, and the potassium iodide by oxidation to iodine with 0·1 N ferrous nitrate solution containing 3 per cent of hydrogen peroxide and starch. The recrystallized products were not contaminated by potassium iodide.

3,5-Diacetylamino-2,4,6-triiodobenzoic acid-^{131}I, 'Urografin' solution 76 per cent (Schering A.G., Berlin), containing 2 gm. of the sodium and 13·2 gm of the methyl-glucamine salt in 20 ml. (2 ml. of the 'Urografin' solution correspond to 1·193 gm. of 3,5-diacetylamino-2,4,6-triiodobenzoic acid) were iodinated by the exchange reaction described above. The yield was 0·775 gm. (65 per cent) of the acid and 66·4 per cent of the original radioactivity. The product was chromatographically pure.

3,5-Diiodo-4-pyridon-N-acetic acid-^{131}I, 70 per cent 'Ioduron' (Cilag A.G.) or 'Diodon' (Spofa) was employed as the diethanolamine salt. 2 ml. 70 per cent 'Ioduron', corresponding to 1·11 gm. of the free acid, was labelled as described above. The yield was 67 per cent of the acid and 70 per cent of the original radioactivity. The product was chromatographically pure.

5 ml. of a 30 per cent solution of the methylglucamine salt of 3,3′-(adipyl-diimino)*bis*-2,4,5-triiodobenzoic acid 'Biligrafin' (Schering A.G., Berlin) containing 1·125 gm. of the free acid was labelled as above. The yield was 45 per cent of the acid and 46·5 per cent of the original radioactivity. The product was chromatographically pure. Identical yields were obtained with the corresponding Spofa product.

The radioactivity of the samples was determined in liquid samples with the aid of a scintillation counter.

Infra-red and the Near Ultra-violet Absorption Spectra of Polyphenyl Derivatives of the Elements of Groups IV*b* and V*b*

We have been investigating the infra-red and the near ultra-violet absorption spectra of several polyphenyl derivatives of the elements of groups IV*b* and V*b*. In the case of the derivatives of the V*b* elements, we have studied the spectra of derivatives where the central atoms possess and do not possess unshared *p*-electrons (derivatives of the atoms in their 'trivalent' and 'pentavalent' states respectively). In addition, we have been studying the spectra of *o*-, *m*- and *p*-substituted tritylbenzenes (trityl = triphenylmethyl). The ultra-violet spectra were recorded in alcohol solutions, and the infra-red spectra in mulls and also in solutions.

Our results on the ultra-violet spectra of the triphenyl derivatives of the V*b* elements ($M\,Ph_3$ where M = V*b* element) agree well with those of Jaffe[1] and show trends similar to the derivatives of the type $Ph\,M\,Me_2$ studied by Bowden and Braude[2]. The ultra-violet spectra of the triphenyl and tetraphenyl halides ($Ph_n M\,X_m$ where X = Cl or Br and $n + m = 5$) are similar to those of the other derivatives of the pentavalent atoms[1–4]. In general, the phenyl derivatives of the V*b* elements in the trivalent state exhibit only one strong absorption band ($n \rightarrow \pi^*$) while the pentavalent atom compounds show vibrational structure ($\pi \rightarrow \pi^*$) similar to the secondary band (B-band at 2500 A.) of benzene itself. This indicates that the unshared *p*-electrons in the trivalent atom derivatives participate in resonance interaction with the π-electrons of the benzene system. This is further demonstrated by the progressive bathochromic shifts observed with the increase in the number of phenyl groups on the central atom. Such variations in spectra are considered to be proportional to the magnitude of the resonance interaction of the phenyl groups with the central atom[5]. The positions of the secondary bands of aniline, diphenylamine and triphenylamine are found to be 2800, 2850 and 2970 A. respectively. The primary band (E-band) seems to vary little, having the values of 2300 and 2280 A. for aniline and triphenylamine. Jaffe[1] did not seem to observe such variations in the secondary bands in the series PhNMe_2, Ph_2NMe and NPh_3 because of the bathochromic shifts due to the methyl groups. He, however, obtained a progressive increase in the primary band wave-length with the number of the methyl groups. It is interesting to see that in spite of the bathochromic shift caused by the methyl groups, P Ph_3 absorbs around 2610 A. compared with 2510 A. in the case of Ph P Me_2. The intensity is also considerably greater in the former compound. The arsenic and antimony derivatives also show similar variations.

Among the $M\,Ph_3$ derivatives of the V*b* elements, N Ph_3 shows the largest hyperchromic effect, which seems reasonable, nitrogen being a first-row element. There is a marked decrease in the wave-length and the intensity in the case of P Ph_3 and a further decrease in the wave-length in As Ph_3. While in phosphorus the 3*d* shell is vacant, in arsenic it is completely filled. But while going from As Ph_3 to Sb Ph_3 and Bi Ph_3 there are progressive shifts to longer wave-lengths (2480, 2560 and 2800 A.). This is considered to be due to the predominating influence of the decreasing ionization potential of the central atom. The importance of the ionization potentials in determining such bathochromic shifts has been recognized[6,7]. Bi Ph_3 also shows another shoulder around 2500 A., which may represent dissociation.

The presence of the vibrational structure of benzene in the derivatives of the pentavalent V*b* atoms indicates negligible or no resonance interaction of the central atoms with the π-electrons of the benzene system. The spectra of these derivatives show little variation with the number of phenyl groups attached to the atom. For example, both tetraphenylstiboniumchloride and triphenylstiboniumdichloride show the absorption maxima at 2700, 2630, 2580 and 2530 A. The derivatives of IV*b* elements behave similarly and show almost no variation in their spectra with the number of phenyl groups. Our results on the phenyl derivatives of IV*b* elements agree with those of Milazzo[8] and of Bowden and Braude[2] on derivatives of the type $PhMR_3$ (R = alkyl group). Among IV*b* derivatives, the silicon derivatives seem to show slightly larger bathochromic shifts, while among the V*b* pentavalent atom compounds, the phosphorus derivatives show larger bathochromic shifts. This may possibly be taken as evidence for the expansion of the valence shell in these two second-row elements.

The ultra-violet spectra of the *o*-, *m*- and *p*-substituted tritylbenzenes also show the vibrational structure of benzene. There is little difference between the spectra of the *p*- and the corresponding *m*-derivatives. The *o*-derivatives seem to exhibit considerable steric interaction. Some of the *p*-substituents which have characteristic absorptions in the ultra-violet, exhibit their absorption maxima at the same wave-lengths as they would in the mono-substituted benzenes. There seems to be little doubt that the *p*-trityl group does not interact with the other substituent or with the benzene ring and that the resonance parameter of the trityl group is approximately zero. Further, the overall electronegativities of the *m*- and *p*-trityl groups were both estimated to be about zero, by a study of the characteristic group frequencies of the *m*- and *p*-derivatives in the infra-red. These conclusions are in accordance with the Hammett reactivity constants of the *m*- and *p*-trityl groups, which have been found to be close to zero by Benkeser and Gosnell[9].

All the polyphenyl derivatives of IV*b* and V*b* elements show mass effects (decrease in frequency with increase in mass) in their infra-red spectra. The mass effects are marked in the C═C skeletal vibrations, in some of the frequencies due to the mono-substituted phenyl group and in one of the C—H out-of-plane deformation bands (750 $cm.^{-1}$). The 750 $cm.^{-1}$ C—H out-of-plane deformation bands of these derivatives show unusual splittings. All these derivatives exhibit bands in the regions 1,440–1,400 $cm.^{-1}$ and 1,100–1,000 $cm.^{-1}$, indicating that such frequencies are by no means unique to P *Ph* or Si *Ph* groups[10]. They might as well be due to some activated ring vibrations.

Further work on these systems is in progress and a detailed report will be published elsewhere at a later date. We wish to thank Prof. R. A. Benkeser of Purdue University for kindly providing the pure samples of the tritylbenzenes.

Binding of Water in Ferric Hydrate

A RECENT communication discussed the infra-red spectra and proton magnetic resonance experiments on some hydroxides and hydrous oxides[1]. We found in the so-called ferric hydrate OH-groups beside free water (adsorbed), that is to say, this compound may be defined as iron(III) hydroxide. In my own communication, the drawing for the infra-red spectrum (Fig. 1) was incorrect; the centre of gravity of curve I should be between $3{\cdot}1$ and $3{\cdot}2\mu$.

In Table 1 herewith, there are the bands of another precipitate with 19·9 per cent water. This was produced from a solution of ferric nitrate with ammonia.

Table 1

Infra-red spectrum of iron(III) hydroxide

Bands in $cm.^{-1}$ (br = broad)	I 3,300 br	II 1,625 br	III 1,030 br
Assignment	OH stretching vibration	H_2O bending vibration	OH bending vibration

From the infra-red spectra of the different iron hydroxides[2], the observed band III is assigned as a bending vibration of the OH-group. The possibility of a combination vibration of the adsorbed water can be excluded. Sometimes this band is split into two. It is possible to calculate[3] the Fe–OH distance with the wave-numbers of the bands I and III as $\sim 1{\cdot}90$ A. This value is of the same order of magnitude as the corresponding distance in the other iron hydroxides (namely, γ-FeOOH, 1·97 A.), and hence the broadening of the bands and the amorphous structure of the compound prejudice the precision of the estimation. The infra-red spectrum of Table 1 may therefore be interpreted as showing that there are OH-groups besides water (adsorbed) in the compound under investigation.

PHYSICAL SCIENCES

Geophysical Effects of High-Altitude Nuclear Explosions

PROMINENCE has been given recently to some geophysical effects of the nuclear tests carried out in August 1958 at Johnston Island in the Pacific. According to newspaper reports[1], these tests included high-altitude explosions at heights of the order of 100 miles on August 1 and August 12; for each date the approximate time of the explosion was 1050 U.T. Observations[2] at Apia, Samoa, show that the test on August 1 coincided with the appearance of an aurora and the occurrence of radio fade-outs at Apia. The special significance of these phenomena is that Apia and Johnston Island lie approximately at opposite ends of a geomagnetic line of force, and the observations at Samoa have been explained[3] as due to the generation of charged particles by the test at Johnston Island and the subsequent guidance of the particles along the line of force to produce increased ionization in the lower ionosphere at Apia,

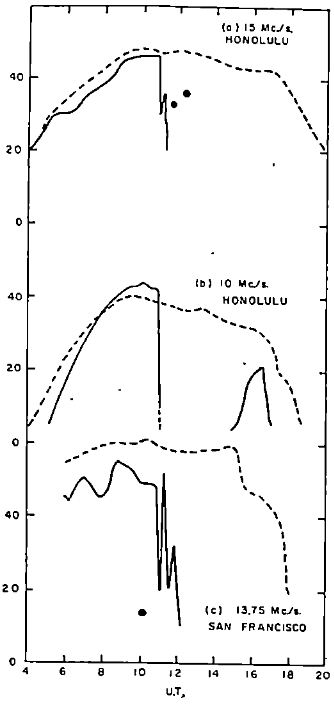

Fig. 1

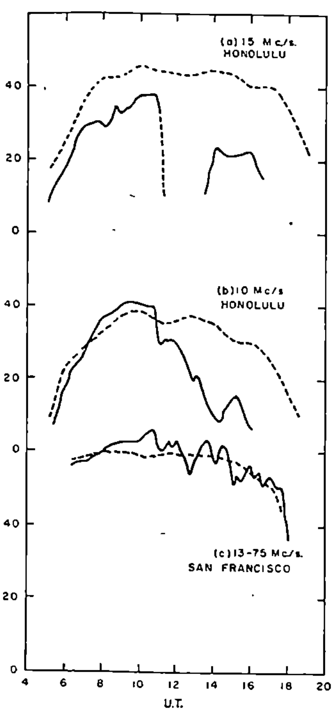

Fig. 2

Fig. 1. Variation with time of signals received at Hiraiso, Japan, on August 1, 1958

Fig. 2. Variation with time of signals received at Hiraiso, Japan, on August 12, 1958

the conjugate point. This mechanism would suggest that any effects are largely restricted to the vicinities of the two ends of the line of force; we wish to present evidence, however, strongly suggesting that increased *D*-layer ionization occurs for distances far greater from the explosion than has hitherto been realized, and at places remote from either the explosion or its geomagnetic conjugate.

Fig. 1 shows the diurnal variation in the strengths of three transmitters as received at the Hiraiso Radio Wave Observatory in Japan; the continuous curve is the record for August 1 and the dotted curve the expected diurnal variation. It may be noted that the time of the explosion coincides with a loss of signal on all three transmitters. The path from Honolulu to Hiraiso passes fairly close to Johnston Island, so that the effects in Figs. 1*a* and *b* are not unexpected. However, the path from San Francisco to Japan is some 3,600 km. from Johnston Island at its nearest point, and, of course, even more remote from the geomagnetic conjugate of Johnston. The records for August 12 are shown in Fig. 2. Again there is a pronounced effect for the Honolulu transmitter on 15 Mc./s. coinciding with the reported time of the explosion, but that on the 10 Mc./s. transmitter is less marked than on August 1, while no significant decrease is detectable for the San Francisco station.

An interesting record is shown on Fig. 3. This is of the integrated level of atmospherics on 28 kc./s. as received at Hiraiso on August 12; an enhancement at the time of the explosion is detectable. The coincidence in time almost certainly implies that the enhancement is due to the nuclear explosion, but there are unusual features. For example, Fig. 3 is dissimilar to the mean diurnal variation of noise on 27 kc./s. shown in Fig. 4, which is derived from Japanese data[4] for August 1957. Normally, one would anticipate the main sources of the atmospherics received in Japan at about 1100 U.T. in August to be in south-eastern Asia and India, with perhaps a subsidiary source, due to the secondary maximum of thunderstorm activity at local dawn, in South America. The enhancement on Fig. 3 could be interpreted as meaning that the source in South America is dominant; that the path of the atmospherics consequently lies close to Johnston; and that the signals are therefore greatly affected. Alternatively, the influence of the explosion may be so widespread as to affect the atmospherics from the thunderstorms in the East Indies, some 7,000 km. from Johnston. A solar flare with its associated sudden ionospheric disturbance could also produce the effect in Fig. 3; there are no reports, however, of such solar activity. Another possibility is a local thunderstorm, but again there are no records of any such storm; incidentally, the 28 kc./s. record for August 1 was completely dominated by thundery activity within Japan. Finally, recent talks at Geneva have shown that the explosion itself can be responsible for the generation of appreciable electromagnetic energy at low frequencies. Many of these alternatives could, of course, be eliminated if conventional wave-form and frequency spectra records for atmospherics were available, particularly if these were coupled with direction-finding and locating systems.

The effects discussed, namely, fade-outs on frequencies of about 10–20 Mc./s. and an enhancement of atmospherics on 28 kc./s., are entirely similar to those accompanying sudden ionospheric disturbance due to a solar flare. The disturbances are known to be caused by the production by the flare of increased

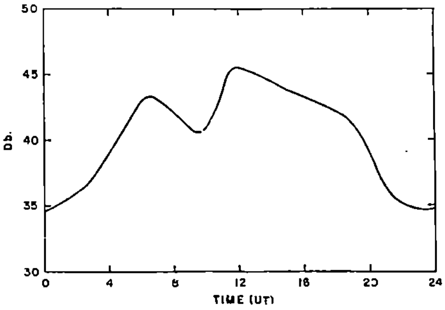

Fig. 4. Mean diurnal variation of atmospheric noise on 27 kc./s. for Japan in August

ionization in the ionospheric *D*-layer. It would appear probable that extra ionization is also produced in the same region by a high-altitude nuclear explosion, perhaps particularly when the explosion lies within the *D*-layer itself (height 70–100 km.). The record of Fig. 1*c* shows conclusively that the effects are not confined to regions influenced by particles guided by the Earth's magnetic field, the mechanism postulated in connexion with the ionization at the geomagnetic conjugate; the addition, incidentally, of precession along a geomagnetic line of latitude[3,5] still implies a considerable restriction in the areas affected. Other mechanisms must therefore also be invoked. Possibilities include analogies with the reported effects of thunderstorms on the ionosphere, including, for example, the direct production of ionization by the electromagnetic radiation of long wave-length generated by the explosion. Again, the production of shock waves with consequent magneto-hydrodynamic influences is feasible; in this connexion the violent oscillations of the record of Fig. 1*c* are intriguing.

Auroral Isochasms

THEORETICAL reasons exist for believing that the auroral isochasms should be projections of circles in the equatorial plane outside the Earth on to its surface along the geomagnetic lines of force[1].

Such projections have been calculated by Hultqvist[2], taking into account up to the fifth term of the spherical harmonic development for epoch 1945. Four such projections on the northern hemisphere are drawn as solid curves in Fig. 1. The projections are ovals with the longest diameter approximately in the plane containing the 170° and 350° geomagnetic meridians. The ovals converge with decreasing diameters towards the point of intersection of Bartels's eccentric dipole with the Earth's surface[2], to which point the geomagnetic north pole is displaced by the higher terms of the harmonic development.

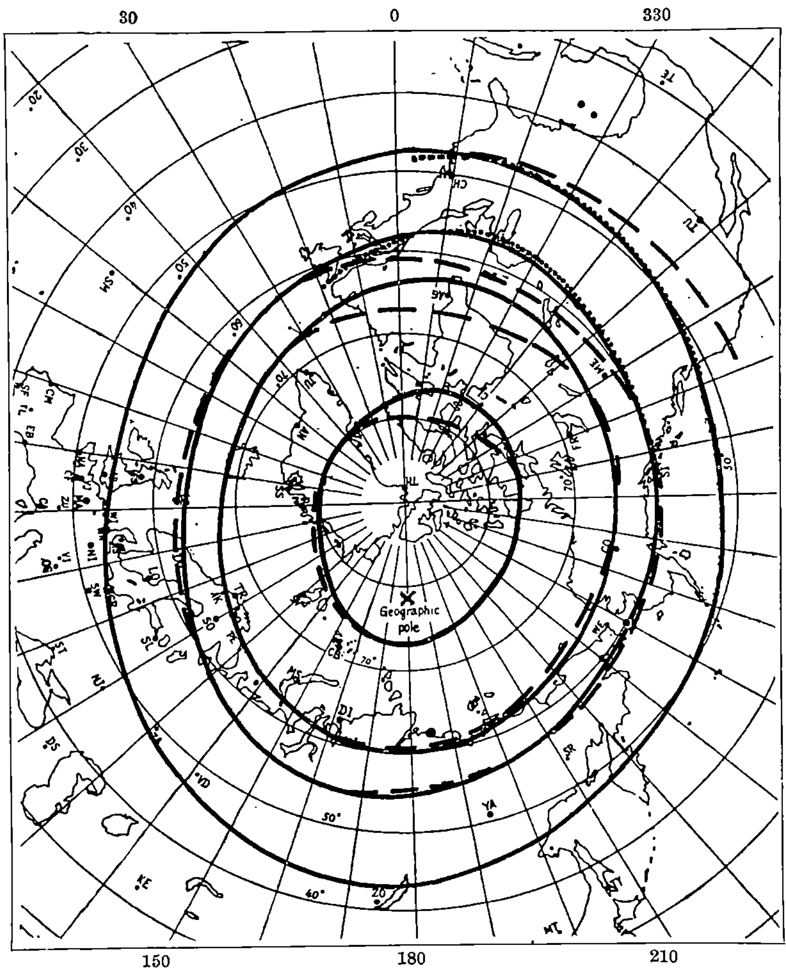

Fig. 1

Some of Vestine's[3] observational isochasms, which closely coincide with the calculated projections over most of the 360° of longitude, are also shown in Fig. 1 (broken lines). It can be seen that for the broken curves the agreement with the theoretical (solid) curves is good except in the region of north-eastern America, where the Vestine curves run up to some 4° too far to the north. The disagreement is so large and so systematic that, on the basis of the curves mentioned, the hypothesis of the isochasms being projections of circles in the equatorial plane seems somewhat doubtful.

Gartlein[4] has recently prepared new isochasms for the territory of the United States based on visual observations made during the International Geophysical Year. Two of those isochasms can be seen in Fig. 1 (dotted lines). They concern just those regions where Vestine's and the calculated isochasms disagree. It is interesting to see that Gartlein's isochasms differ considerably from Vestine's and agree very well with the theoretical curves. Only in the extreme eastern part—chiefly over the sea—do they appear a little too much to the north. The agreement is surprisingly good, especially for Gartlein's southernmost curve, if the uncertainty inherent in the method of evaluation of the observational curves is taken into account.

Thus the agreement between observed isochasms and projections of circles in the equatorial plane along the lines of force seems to be good, in view of the uncertainty mentioned above of the experimental isochasms definitely demonstrated by the disagreement between Vestine's and Gartlein's curves.

Possible Causes of Geomagnetic Fluctuations having a 6-Sec. Period

WE have delayed comment on F. B. Daniels's letter in *Nature*[1] hoping that we would obtain further information relevant to his suggestion that the fluctuations of about 6 sec. period in the geomagnetic field may be due either to microseisms or microbaroms. Although the general object of our main investigation has been to get a clear idea of the cause and origin of the geomagnetic fluctuations in a wide frequency-range, the main emphasis has been in the normal 'daytime' *pulsations continues* of 10–40 sec. period. The particular record referred to by Dr. Daniels[2] was taken during a magnetic storm, when geomagnetic fluctuations cover a range of periods from fractions of a second up to many minutes.

We have, however, observed that fluctuations in the range of 1–7 sec. period do sometimes appear on our records of $\delta X/\delta t$, $\delta Y/\delta t$ and $\delta Z/\delta t$ nearly simultaneously at two sites some hundreds of miles apart.

We have not attempted to measure microbaroms and would certainly encourage an investigation such as Dr. Daniels suggests, since it is possible that microbaroms are associated with some types of geomagnetic fluctuations. For example, pressure changes in the ionosphere may result from the influx of particulate charged material.

Recently, we have been paying more attention to fluctuations during the hours of darkness and especially during the magnetically quiet time of night. At this time, geomagnetic fluctuations may be associated with particulate matter from the Sun but probably not with direct radiation. We have noted a number of occasions when a characteristic damped fluctuation of about 1–3 min. period and maximum amplitude of ½–2 gamma is readily related to a similar phenomenon simultaneously recorded some hundreds of miles away. However, the most interesting feature is that fluctuations of this type are sometimes associated with oscillations of periods of 2–7 sec. Rarely, these precede the main phenomenon by a minute or so, but more often they accompany it, and may continue for some time if the general magnetic activity is maintained. We believe the short and long periods are associated and both of electromagnetic origin.

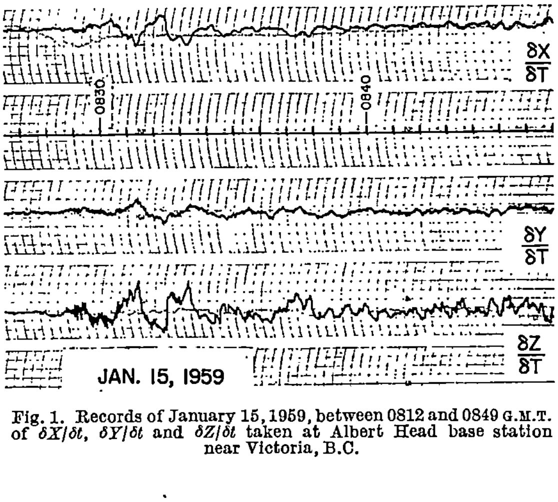

Fig. 1. Records of January 15, 1959, between 0812 and 0849 G.M.T. of $\delta X/\delta t$, $\delta Y/\delta t$ and $\delta Z/\delta t$ taken at Albert Head base station near Victoria, B.C.

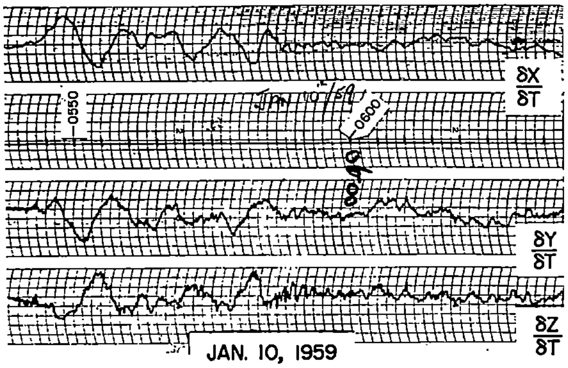

Fig. 2. Records of January 10, 1959, between 0544 and 0610 G.M.T. of $\delta X/\delta t$, $\delta Y/\delta t$ and $\delta Z/\delta t$ taken at Albert Head base station near Victoria, B.C.

Two dates which show the short-period oscillations starting just before the main train are 0819·7 on January 15, 1959, and about 0548·0 on January 10, 1959, G.M.T. We have been informed by Prof. Hugo Benioff that his seismograph records at the California Institute of Technology do not exhibit oscillations starting or increasing at the times and on the days mentioned, and we have not observed any association with the local Dominion Astrophysical Observatory seismograms.

Figs. 1 and 2 show the records at our base station near Victoria, B.C., for the two dates referred to above. The records for $\delta X/\delta t$, $\delta Y/\delta t$ and $\delta Z/\delta t$ are shown. Full scale on each record is about 1 gamma for the longer-period fluctuation. Fig. 3 shows the simultaneous records of $\delta X/\delta t$ at our base station and of $\delta Z/\delta t$ near Borrego Springs about 1,100 miles away in southern California.

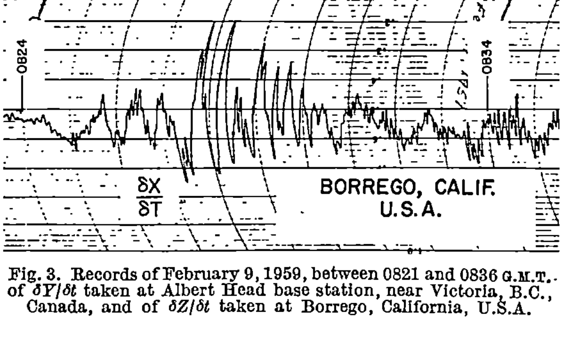

Fig. 3. Records of February 9, 1959, between 0821 and 0836 G.M.T. of $\delta Y/\delta t$ taken at Albert Head base station, near Victoria, B.C., Canada, and of $\delta Z/\delta t$ taken at Borrego, California, U.S.A.

It is probable that these fluctuations are associated with the 'oscillatory bursts' in earth-current records examined by V. A. Troyiçkaya. These, she states, are persistently associated with characteristic (magnetic) oscillations having a period of the order of 2–3 sec.[3].

The longer-period damped fluctuations are of interest in another respect. Examination of the magnetograms of the local Dominion Observatory, of which Mr. Bernard Caner has kindly supplied copies, shows that these damped fluctuations can often be recognized on the magnetograph records as a very sudden and small displacement of *H*, *D* and *V* (from 1 gamma upwards). While these displacements may be seen by looking for them at the times suggested by the fluctuation records, the reverse procedure is not very effective.

It is difficult and costly for us to record the geomagnetic fluctuations at far distant places when we are dependent on transport of heavy equipment. Thus we have not operated simultaneously a pair of stations much more than 1,000 miles apart. We believe, however, that this type of fluctuation, which is most obvious in the early part of the night when the general activity is low, may be shown on the magnetograms of observatories covering a large area. We think this examination should be made and will willingly supply dates and times when these fluctuations have been recorded at our base station within the past few months.

Origin of Sodium and Lithium in the Upper Atmosphere

Lithium resonance radiation in the twilight airglow of the southern hemisphere has recently been observed in several places[1,2]. Over Adelie Land in the Antarctic this radiation is reported to have been present both in 1957 and 1958. In October 1957 its intensity was estimated visually to be of the order of a tenth that of the sodium *D* lines in the twilight. After the high-altitude nuclear bomb explosion in the Pacific in August 1958 this radiation was also observed at Hallett Station in the Antarctic and afterwards in September at Invercargill in New Zealand. Its intensity is roughly estimated as equal to the total sodium *D* line intensity at Hallett in August and a tenth of this in New Zealand in September.

An attempt has been made to estimate the ratio of free lithium to free sodium from the intensity ratios found[3]. This estimate was based on the assumption that, apart from a factor of 17 arising from the presence of the Fraunhofer *D* lines in the solar spectrum and slightly different oscillator strengths, the abundance ratio is equal to the intensity ratio. The conclusion reached is that the ratio of the abundance of lithium to sodium is of the order of 0·006 (perhaps even 0·02 if ions are also considered). Compared with a ratio of 0·002 expected if the common origin of these elements in the Earth's atmosphere is meteoric debris, and a ratio of $2{\cdot}3 \times 10^{-5}$ expected if their origin is in sea water, the result is taken as strong evidence for the meteoric source.

Similarly, from the New Zealand and Hallett observations an attempt has been made to estimate the amount of lithium in the atmosphere, again on the assumption that sodium and lithium intensities in the twilight airglow are proportional to their abundances[2]. This calculation takes an old estimate of 6×10^9 atoms/cm.^{2} for the abundance of sodium and suggests that the quantity of lithium in the upper atmosphere fell from 20 kgm. to 2 kgm. between August 5 and September 5.

Because of resonance absorption of sunlight in the layers, the assumption of linearity is a very poor one, however, at least in the case of sodium[4]. In fact, the increase of intensity of scattering with abundance becomes significantly less than linear for abundance of sodium in excess of 10^9 atoms/cm.^{2}. In the neighbourhood of 25×10^9 atoms/cm.^{2}, the intensity actually passes through a maximum and declines very slowly for larger quantities of sodium. This non-linearity makes any estimate of the lithium–sodium abundance ratio impossible from the intensity ratios alone. An absolute determination of the quantity of one or the other present is also necessary. Even then the double value in the intensity abundance curve may leave the situation ambiguous.

The season for which the lithium observations are reported was late winter. This is the very time when the seasonal maximum in sodium abundance would be expected. In the northern hemisphere there occurs a sodium maximum at the inland station of Saskatoon in Canada of about 10×10^9 atoms/cm.^{2} in late February. At Haute-Provence Observatory in southern France intensity peaks corresponding to abundances in the neighbourhood of 25×10^9 atoms/cm.^{2} are reached in December and March. Between these intensity maxima lies a minimum in February with which abundances as low as 5×10^9 atoms/cm.^{2} and higher than 100×10^9 atoms/cm.^{2} are consistent because of the maximum in the abundance-intensity curve.

If the sodium in the southern hemisphere behaves similarly, and particularly if the seasonal variation is like that observed in France, sodium abundances from 5×10^9 atoms/cm.^{2} to more than 100×10^9 atoms/cm.^{2} cannot be excluded in August. For this range of abundance the variation of intensity is so small that any quantity of sodium between these limits would be consistent with $3/17 \times 10^8$ atoms of lithium/cm.^{2} and an intensity ratio of the order of 0·1. From the measurements available, therefore, it is safe to conclude only that the lithium–sodium ratio lay somewhere between 0·006 and 2×10^{-5} or, more probably, between 0·0035 and 0·0006.

Of course, the Johnson Island nuclear explosion on August 1, 1958, may very well be the source of at least part of the lithium observed[5]. Lithium–sodium intensity measurements as a consequence have become even less useful in solving the problem of the origin of the atmospheric sodium.

On this question there are three pieces of evidence, none of them conclusive. There were the repeated observations from southern France during 1955 and 1956 of much more sodium towards the Atlantic Ocean than towards the Continent[4]. There is a remarkably different seasonal variation in sodium near the ocean than is found far inland, with much more sodium near the ocean[6]. Finally, there is the recent attempt by Lytle and Hunten[7] to detect the resonance lines of potassium in twilight. This places an upper limit of 1 : 40 on the potassium–sodium ratio, whereas sea water has a ratio of 1 : 47 and all other sources between 1 : 10 and 1 : 5. At this time the evidence must be taken as favouring a marine origin.

The work reported here was supported in part by a grant from the National Science Foundation.

Effect of Cathode Inclusions on Electrical Discharges

Recognition has been given for some considerable time now to the fact that the surface of the negative electrode in a spark gap can influence the electrical discharge[1]. An attempt has been made to ascertain the location of the starting place of arc spots in relation to the metallurgical features of the cathodes.

As is well known, metals frequently contain microscopically visible inclusions often of more than one type chemically. In stainless steels, with which we have been principally concerned, oxides, nitrides, carbides, slag particles and pieces of refractories are the major inclusions.

Microscopical examination of clean polished specimens which had been used as negative electrodes in a small experimental spark gap showed that metal had vapourized from around certain inclusions, the bulk of the material being unaffected. It is of considerable interest to note that the inclusions affected possessed low electrical conductivity whereas inclusions of relatively good conductivity were entirely unaffected.

This phenomenon is by no means peculiar to stainless steels. For example, localized damage has been found around cuprous oxide inclusions in samples of copper. Cuprous oxide also has a low electrical conductivity. The current passing in these experiments under non-arcing conditions was approximately $1\cdot6 \times 10^{-4}$ amp. cm.$^{-2}$ and the minimum resistivity for arc initiation appears to be 10^3 ohm. cm.

This work, which forms part of a programme to investigate surface properties of metals, is to be reported in detail elsewhere.

X-ray Spectrographic Determination of Strontium

Roberts[1] recently described an X-ray fluorescence spectrographic method for the determination of strontium in animal bone using the Philips *PW* 1520 spectrograph fitted with a quartz analysing crystal. In our laboratories a lithium fluoride crystal was available and was used for similar analyses since, compared with a quartz crystal, it increases the intensity of the strontium *Kα* line by a factor of 2·8 and the line/background ratio by a factor of 1·15. Thus the counting time to achieve a given coefficient of variation (due to the counting statistics) can be reduced by a factor of 3·5 or, if the same counting time is compared, the coefficient of variation can be reduced by a factor of 1·9, by using the lithium fluoride crystal.

The instrumental conditions were: Philips X-ray spectrograph, *PW* 1520; tungsten target tube, 48 kV., 20 m.amp.; argon-filled Geiger counter; X-ray path evacuated; exit collimator not fitted. Samples were prepared in a manner similar to that described by Roberts, but the 'Mylar' film was not removed from the sample holder because of the potential danger of contamination of the window of the X-ray tube. The absorption of the strontium radiation by this film is theoretically about 0·1 per cent and, in practice, was not detected.

The specific intensity of the strontium *Kα* line from milk powder ash was found to be identical with that from animal bone ash, and results obtained by several different methods for both these types of sample are compared in Table 1.

Table 1

Sample	Strontium content (p.p.m.)			
	X-ray spectrography	Emission spectrography (ref. 2)	Neutron activation*	Flame photometry (ref. 2)
Bone ash				
1	90	90	89	89
2	120	109	—	124
3	198	190	—	192
4	340	345	—	335
Milk ash				
1	33	36	33	32
2	34	31	32	33
3	56	45	53	51
4	65	64	65	64

* Determinations carried out by Dr. G. E. Harrison and Mrs. E. Sowden, Medical Research Council Radiobiological Unit, Atomic Energy Research Establishment, Harwell.

Since these determinations were carried out, a molybdenum-target X-ray tube has been obtained and shown to increase the intensity of the strontium line by a factor of 1·5 and improve the line/background ratio by a factor of 2·5. Thus with this tube and a lithium fluoride crystal it is possible to determine 10 p.p.m. strontium in bone or milk powder ashes in 30 min. with a coefficient of variation due to the counting statistics of 10 per cent.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, May 26

University of London (at Imperial College of Science and Technology, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. W. O. James, F.R.S.: "Botany—Here and Now".* (Inaugural Lecture.)

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Mr. A. F. Shore: "Animals in Ancient Egypt".* (Fourth of six lectures on "Animals in Archæology". Further lectures on June 2 and 9.)

Tuesday, May 26—Friday, June 5

National Union of Teachers (at the National Hall, Olympia, London)—National Education and Careers Exhibition.*

Wednesday, May 27

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Dr. J. Kiefer: "Optimum Experimental Designs".

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Annual General Meeting, followed by Dr. J. R. Nicholls: "Food and Ordinary Man".

Jephcott Lectures Trust (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 7 p.m.—Sir Alexander R. Todd, F.R.S.: "Nucleic Acids and their Role in Future Chemotherapy of Tumours and Virus Diseases" (First Jephcott Lecture).

British Psychological Society, Medical Section (in the House of the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 8.30 p.m.—Dr. Henri Rey: "Studies on the Relationship of Hormones, Brain Activity and Behaviour in Women".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Sir Harold Spencer Jones, F.R.S.: "Some Principles of Clock and Watch Design".

Thursday, May 28

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Dr. E. E. Pochin: "The Therapeutic Use of Radio-iodine".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. P. Bell, F.R.S., and Mr. T. Spencer: "Kinetics of the Base-Catalysed Bromination of Ethyl Nitroacetate"; Mr. C. F. Cullis, Mr. F. R. F. Hardy and Mr. D. W. Turner: "The Point of Oxygen Attack in the Combustion of Hydrocarbons. II: The Formation and Origin of Ketones".

Institute of Metals (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. N. J. Petch: "The Atomic Mechanisms of Fracture".

Friday, May 29

University College, Department of Mathematics (in the Eugenics Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. Thom (University of Strasbourg): "General Position and Transversality".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Civil Engineering—The Registrar, The University, Sheffield (May 30).

Lecturer (with a university degree, and preferably previous forensic experience) in Forensic Chemistry in the Department of Forensic Medicine—The Secretary, The University, Edinburgh (May 30).

Map Curator and Cartographer (graduate in geography with a special interest in cartography and map preparation) in the Department of Geography—The Registrar, University College, Singleton Park, Swansea (May 30).

Demonstrator (with a good honours degree in physiology, biochemistry or chemistry) in Chemical Physiology—The Registrar, The University, Manchester 13 (June 1).

Assistant Librarian (with a university degree)—The Secretary, The University, Aberdeen (June 5).

Lecturer (specialized in parasitology) in the Department of Zoology—The Registrar, The University, Hull (June 6).

Assistant Lecturer (preferably with a knowledge of embryology or vertebrates) in the Department of Zoology—The Registrar, University College of Wales, Aberystwyth (June 12).

Lecturer or Assistant Lecturer in Electronics—The Secretary and Registrar, The University, Southampton (June 12).

Electron Microscopist (graduate in medicine, biology or physics, and experienced in the operation and maintenance of a high-resolution instrument (preferably Siemens) and in the techniques of specimen preparation) in the Department of Physiology and Histology—The Registrar, The University, Liverpool (June 13).

Lecturer and an Assistant Lecturer in Physics—The Registrar, The University, Hull (June 13).

Demonstrator (with a degree in agriculture or an honours degree in pure science followed by an adequate postgraduate qualification in agriculture, and preferably some training in field experimentation)—The Secretary, School of Agriculture, The University, Downing Street, Cambridge (June 15).

Scientific Officer (with a good honours degree in botany and preferably experience in plant physiological research) in the Botany Department, for work on the physiology of the sugar beet plant, especially on the causes of variation in yield of field crops—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (June 15).

Electronic Computing Engineer (university graduate experienced in the development and design of electronic computing equipment) on the staff of the Adolph Basser Computing Laboratory in the School of Physics, to assume responsibility for a part of the development programme—The Registrar, University of Sydney, Sydney, N.S.W., Australia (June 19).

Assistant Experimental Officer (with a degree in a biological subject and practical experience in bacteriological methods and techniques), for work on the ecology of soil micro-organisms—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (June 30).

Botanist (with an honours degree in botany from a recognized university and preferably at least two years postgraduate experience), for duties particularly concerned with the study of the growth characteristics of the tea bush in the chief soil-climatic regions of East Africa, the study and provision of improved planting material, and the botanical interpretation of field experiments—The Director, Tea Research Institute of East Africa, P.O. Box 91, Kericho, Kenya Colony (June 30).

Research Assistants (with an honours degree of a British university or equivalent qualification) in Plant Biochemistry, Electrical Engineering, Applied Physics, Mechanical Engineering, Applied Chemistry, Mining, and Biochemical Microbiology—The Principal, Heriot-Watt College, Edinburgh (June 30).

Soil Scientist (with a Ph.D. degree in soil chemistry and preferably with some experience), to carry out soil fertility investigations, both applied and fundamental, in relation to tobacco, and to supervise soil analysis—The Director, Tobacco Research Board of Rhodesia and Nyasaland, P.O. Box 1909, Salisbury, Southern Rhodesia (June 30).

Assistant Lecturer (Grade B) in Chemistry—The Principal, Peel Park Technical College, Salford 5.

Chair of Engineering—The Registrar, The University, Leicester.

Head (with high academic qualifications, and experience of full-time teaching, together with industrial and/or research experience) of Physics and Mathematics Department (Grade IV)—The Registrar, Portsmouth College of Technology, Portsmouth.

Lecturer in Forestry—The Principal, Royal Agricultural College, Cirencester.

Physicist, Basic grade (with a first- or second-class honours degree), for routine and development work in hospital physics—The Secretary, Lambeth Hospital, Brook Drive, London, S.E.11.

Plant Pathologist (with a good honours degree in botany or plant pathology and approved postgraduate training) in Kenya, for laboratory and field research work on the identification and control of plant diseases—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/7/030.

Plant Pathologist (with a good honours degree in botany and with two years postgraduate experience in plant pathology) in the Department of Agricultural Research, Federation of Nigeria, for research into virus diseases of food crops—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/14/035.

Special Officer (Statistician) (with a good honours degree, preferably in agriculture, with at least two years suitable postgraduate training or experience in statistics) in the Northern Region of Nigeria, to advise on the design and supervise analysis and presentation of results of experimental work for all sections of the Research Branch of the Northern Region Department of Agriculture, and to take part in the development of satisfactory experimental techniques in the field—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/408/032.

High performance at Low wavelengths

The absorption spectrum of maleic acid reproduced here emphasises the excellent performance of the SP.500 spectrophotometer at low wavelengths. The second graph shows the Beer-Lambert relationship at 210mμ, and illustrates the virtual freedom from stray light at this wavelength.

With the new fused silica prism, the SP.500 Spectrophotometer reaches still further into the ultraviolet—down to 186mμ, the limit set by the absorption bands of atmospheric oxygen. The advantages of this are two-fold: a new region, hitherto accessible only to specially prepared instruments is made available for every user, and the performance of the instrument, over the whole of the important 200mμ—240mμ region, reaches a new high level. The standard test specification for the SP.500 now stipulates not more than 0.2% stray light at 200mμ—a clear indication of the instrument's quality.

RECRUITMENT IN GOVERNMENT SERVICES AND SECURITY REGULATIONS

THE White Paper dealing with defence is this year entitled "Progress of the Five-Year Defence Plan"* and is much shorter than last year's White Paper. "Defence Statistics 1959/60"†, however, have been collected in a separate White Paper, and there was also issued, in July 1958, a further White Paper, "Central Organisation for Defence"‡. The Defence Budget is given as £1,502·13 million net, of which £585·46 million is on research and development. There is no separate entry under this heading for the Ministry of Defence, but for the Admiralty, the War Office, the Air Ministry and the Ministry of Supply the respective net figures for research and development are £169·03 million, £53·68 million, £213·85 million and £148·90 million. Gross expenditure under this heading by the Ministry of Supply is £521·60 million.

Despite these figures there is, however, no other specific reference to research in any of these White Papers. There is, in the one reporting on progress, a reference to the valuable exchange of information with the United States which has permitted important technical advances to be made in the design of nuclear war-heads, and it is stated that after a recent review of the British ballistic rocket programme, in the light of technical developments in Britain and in the United States, the Government reached the conclusion that, on present knowledge, *Blue Streak* is the type of missile best suited to British needs. It is obvious that the modernization of the Fleet and the re-equipment of the Army are both based on much technological research, but the magnitude of this effort is nowhere disclosed, nor is there any indication as to how effectively it is co-ordinated.

On the Defence Research Policy Committee there is again silence, nor is the Committee even mentioned in the White Paper dealing with the central organization for defence. The latter paper formally announces the confirmation, as a result of eighteen months experience, of the re-organization of the Ministry of Defence announced by the Prime Minister on January 24, 1957, with the introduction of three new features. First, the composition and operation of the Defence Committee of the Cabinet are being adjusted to secure greater flexibility and efficiency. Secondly, a Defence Board is being set up to assist the Minister of Defence in formulating a defence policy and in dealing with inter-Service problems. Some adjustments are also being made in the staff organization, including the creation of a new post, Chief of the Defence Staff, in place of the existing combined posts of Chairman of the Chiefs of Staff Committee and Chief of Staff to the Minister of Defence. The holder of this post will be responsible to the Minister of Defence and will be his principal military adviser. He will also be a member of the Defence Board, of which the Minister of Defence will be chairman. The other members of the Board are the Ministers for the three Service Departments, the Minister of Supply, the Chief of the Naval Staff, the Chief of the Imperial General Staff, the Chief of the Air Staff, the Permanent Secretary of the Ministry of Defence and the Chief Scientist of the Ministry of Defence. As already noted, there is no reference to the Defence Research Policy Committee, nor, although in the defence statistics the interrelation of defence and civil expenditure is fully recognized, to the Advisory Council on Scientific Policy. Formal or even informal arrangements for the correlation of defence and civil requirements in the research and development effort in Britain appear to be lacking.

This aspect of the defence effort was scarcely discussed in the subsequent Parliamentary debates although the dependence of effective defence on scientific and technical advance was generally recognized. There was, however, a significant admission by the Minister of Supply, Mr. Aubrey Jones, in replying for the Government in the debate in the House of Commons on February 26. While the Minister of Defence had given most encouraging accounts of recruitment to the Armed Forces, Mr. Jones admitted he could not be quite so encouraging about the recruitment of scientists to the Government's defence establishments. He could offer no improvements in pay or amenities, but he hoped that due advantage would be taken of the unrivalled opportunities for research which he could offer.

Even more significant, however, was Vice-Admiral J. H. Hallett's reference to secrecy. . Vice-Admiral Hallett was concerned primarily with the modernization of the Fleet and whether this was being carried out appropriately for the functions it would perform, particularly in respect of the defence of communications and the threat of submarine warfare. He pointed out, however, that no one outside a small circle of Service officers, Government officials and possibly senior Ministers could hope to answer the vital questions because they did not possess the information which is the essential basis of any opinion worth while.

That is equally true of any other section of defence policy, and Admiral Hallett reminded the House of Commons that this is a novel and dangerous position. In the past, military thinking in Britain has been enriched by the contributions of people outside the Services, outside the Government and outside politics and public life altogether. Often such contributions have profoundly influenced the thought of junior officers, who incidentally themselves had access to the information on which to reach independent judgments of their own.

---

* Progress of the Five-Year Defence Plan. Pp. iii+7. (Cmnd. 662.) (London: H.M. Stationery Office, 1959.) 9*d*. net.

† Defence Statistics 1959/60. Pp. 8. (Cmnd. 661.) (London: H.M. Stationery Office, 1959.) 9*d*. net.

‡ Central Organisation for Defence. Pp. 6. (Cmnd. 476.) (London: H.M. Stationery Office, 1958.) 6*d*. net.

That, said Admiral Hallett, has all changed, and although such writers are still to be found, their contributions are now based essentially on guesswork, and very few people indeed possess the vital information without which the study of tactics and strategy is waste of time. The great danger, moreover, is that the handful of experts who alone possess the information are not necessarily the people best qualified to interpret it. Admiral Hallett illustrated this by our experience in the development of radar, when the secrecy with which this was developed led to its applications in naval warfare being overlooked, and he urged the Government to consider very seriously whether the present secrecy is any longer in the true interests of national security.

The impossibility of any effective discussion of the scientific and technical aspects of defence policy in the light of information publicly available was pointed out in these columns in commenting on the White Paper on defence last year. It is obvious that Admiral Hallett is uneasy as to the situation from the Services point of view and his disquiet is based, moreover, on his experience as vice-controller of the Navy and as second-in-command of the Anglo-American Striking Fleet. Indeed, experience in the latter post made him particularly anxious as to the effect of secrecy on the Anglo-American exchange of scientific and technical experience.

These comments seem to reinforce doubts as to whether the Defence Research Policy Committee is functioning effectively, and as to its relations with the Advisory Council on Scientific Policy. Even with adequate informal contacts, the present structure appears to place an excessive responsibility on the common chairmanship, and makes informal discussion in scientific and technical circles not merely desirable but even essential. This is as important from the point of view of efficient use of the limited resources of Great Britain both of materials and of man-power as it is from that of the wise direction of policy, and would go far to establish the public confidence which is always an essential element in effective defence. To say the least, Mr. Orr-Ewing's reply to a question to the Minister of Defence on April 8 as to what consideration the Defence Research Policy Committee has given to the effect of the resignation of scientific research workers as a result of the uncertainty of Government policy is not helpful. Conformity with established practice is no longer a sufficient reason for secrecy and a refusal to promote public discussion. Secrecy may be one reason why the Minister of Supply finds it difficult to recruit sufficient scientists for his research establishments. Even unrivalled material facilities and equipment will not attract first-class minds if they are doubtful as to the value of their work, or the possibility of the free discussion of results among their fellows with the cross-fertilization of minds upon which scientific advance depends.

PRESENT TRENDS IN BOTANICAL STUDIES

Vistas in Botany

A Volume in Honour of the Bicentenary of the Royal Botanic Gardens, Kew. Edited by Dr. W. B. Turrill. (International Series of Monographs on Pure and Applied Biology. Division: Botany, Vol. 2.) Pp. xv+547. (London and New York: Pergamon Press, 1959.)

An occasion such as the bicentenary of the Royal Botanic Gardens, Kew, offers a rare opportunity to take stock of the present position in botany and of desirable trends for the future [see also p. 1488 of this issue]. The present volume, edited by W. B. Turrill, represents an attempt to do this. It consists of surveys of different facets of botanical inquiry by well-known authorities, and though perhaps it emphasizes those aspects of the subject which have especially been the pre-occupation of Kew, it covers so wide a field that there are few botanists who will not feel constrained to consult its pages and few who will put it down without having profited by its perusal.

Without any wish to make invidious comparisons, which would indeed require unprecedented knowledge in a variety of subjects, it is evident that the distinguished authors of these pages have looked at their limited fields in very diverse ways. Some have succeeded in discovering and presenting a fair and attractive vista; others perhaps have scarcely been able to see the wood as a whole but have not missed a tree, while still others have been so interested in the first tree that they have scarcely gone beyond it. In each of the several styles there is at least one example which is masterly of its kind, and the diversity of treatment adds piquancy to one's reading and is a welcome change from the monotony of a series of 'reviews of the present position'.

The plan of the work thus is a series of surveys of the main groups of plants coupled with special statements about the more general botanical problems. There is a historical preface by the Editor, and the first paper is a short introductory one by the present director of the Royal Botanic Gardens, Kew, Dr. George Taylor.

The massive contributions of Kew to taxonomy justify pride of place being given to an article on this subject by H. J. Lam. This ranges widely over what may perhaps be called the basic theories underlying classification, taxonomy and systematics, with a sufficiently individual point of view, perhaps fundamentally classical and morphological, to integrate wide reading with interesting and suggestive reflexion. Rudolfo E. P. Pichi-Sermolli also accepts taxonomy as the synthesis of all biological knowledge and exemplifies this point of view in his exhaustive treatment of the Pteridophyta, in which, after surveying the development of present knowledge, he delves deeply into the problems of phylogeny in the various taxa of this great group. In dealing with the Gymnosperms, W. B. Turrill, apart from a discussion of the 'telome' hypothesis, has to accept the limitations due to modern conceptions of the Gymnosperms as a group of phyla offering vistas of several diverse types, in which the peculiarities of the reproductive systems in comparison with the Angiosperms occupy a prominent place. P. W. Richards records much of interest in the Bryophyta, especially to ecologists and morphogeneticists, in relation to the developmental stages, the alternation of forms and their evolution. The Algae are considered by W. R. Taylor, "Phycology in Retrospect and Anticipation", who directs attention to the enormous gaps existing even in the taxonomy of the group from which the higher plants must have evolved. Particularly can one note the lack of an organized embryology and even of essential cytological detail. In contrast there is a high degree of knowledge in some limited fields of algal physiology, ecology and utilization. C. T. Ingold's admirable survey of the very extensive literature on Fungi shows how much studies of this group have contributed to general botanical problems, particularly perhaps those of sex and inheritance, while the physiology of their nutrition has much to give to problems of morphogenesis through hormone control, as well as to knowledge of antibiotics. K. A. Bissett has faced with success the difficult task of treating the bacteria as organisms rather than as biochemical or medical entities.

While the study of the larger groups of plants and their taxonomy has been pursued for many years, that of the viruses, if indeed they are to be classified as plants, is comparatively recent, and as F. C. Bawden points out, has only made much progress in the past two or three decades with the rapid advances in the chemical and physical methods developed for enzymology. The fascinating story of their crystal structure and intimate relation to other nucleoproteins has made the viruses of even greater interest to the general biologist than to the plant pathologists who first recognized them. This is equally true of the details of cytological structure revealed by D. G. Catcheside, who, switching skilfully from cytoplasm to chromosomes and bacteriophage, marshals the evidence that deoxyribonucleic acid is the significant part of the nucleus providing genetic information. These two papers are, in fact, a valuable source of ideas for those not very familiar with rapidly advancing fields of work. Also essentially analytical in outlook is the article on biochemistry by E. C. Bate-Smith. Perhaps the most interesting part of this is an appreciation of the possibilities of comparative biochemistry in plants which, it is thought, will be based on secondary products rather than those common to all organisms. The useful biochemical processes for the purpose of phylogenetic comparisons would thus be those present in a series of forms, but lost and not regained in their successors, as apparently may be the case in some of the leucoanthocyanins.

A long period of inertia followed the early anatomical discoveries of Grew and Malpighi, and in tracing the re-development of plant anatomy, C. R. Metcalfe illustrates the leading part played by the Jodrell Laboratory at Kew in Great Britain. Perhaps more important than his plea for "brighter" anatomy teaching is the need he stresses for organizing the enormous amount of material which must be available for comparative use, particularly perhaps in the Angiosperms. Another subject, palæobotany, profited greatly from the activities of the Jodrell Laboratory under D. H. Scott, and indeed from the fact that three of the directors of Kew, Sir Joseph Hooker, Sir Arthur Hill and Sir Edward Salisbury, have engaged in palæobotanical research. John Walton's sympathetic account of the personalities who have led the way in this field in Britain, and of their views, must be in many ways the best of the pure 'vistas', Sewardian in quality.

If some of the more modern aspects of the subject illustrate the value and the use of the analytical method, the considerable paper, "Genes, Chromosomes and Evolution", by G. L. Stebbins, offers in contrast an approach through the widest fields of cytogenetics and floristics which has also become popular in the past twenty years and which aims at integrating the facts of distribution, taxonomy and cytology in terms of the most recent genetical theory. Plant geography, as W. B. Turrill shows in a notable and comprehensive treatment, also integrates a great deal of material of general and evolutionary interest, as well as seeking to classify distributional units and arrange them in provisional and more useful hierarchies. The characteristics of plant sociological units and their groupings are considered in greater detail by J. Braun-Blanquet ("Grundfagen und Aufgaben der Pflanzensociologie") together with their relations to synecology, to community succession and (somewhat sceptically) to statistics. Causal plant ecology is treated by a former director of Kew, Sir Edward Salisbury, who considers it as running parallel to physiology, the relation of plant growth to physical and chemical environmental characters, but subject to the additional stresses imposed by competition. In these circumstances, extremes of environment, particularly in relation to phases of growth, are often more decisive in nature than average conditions, while rooting conditions are especially important in competition. Appropriately in this connexion, the paper on plant physiology by F. A. C. Went lays emphasis on the control of plant growth by temperature regimes, by photoperiodism, and by hormones, as well as directing attention to the tendency to locate individual chemical processes in special localities, either in the cell or in special sites in the tissues.

A comprehensive volume of this type will always leave the reader with at least some impressions about the subject surveyed. Biologists can rarely get far away from the central topics of evolution and taxonomy, nowadays perhaps accompanied by the study of the mechanisms of heredity, and these ensure a considerable integration of any large series of general botanical papers such as this. But the reader is also made aware of what is becoming an increasingly important aspect of biological work, the physical difficulty, to say nothing of the intellectual one, of maintaining an organization in which the vast accessions of material and knowledge can be stored in a readily available form and integrated for general use. It seems without question that this is only possible in an institution such as that at Kew, and one is able to appreciate properly how an organization based on gardens, herbaria and laboratory has done so much for taxonomy in particular and for botany in general. Whether this is the organization most suitable for the widest type of integration is no doubt a question which would require very detailed discussion. Perhaps the second point emerging from this survey of the botanical field is the very large gap remaining in our knowledge of the relations between growth and morphological development, and particularly of the chemistry and mechanics of developing cells and tissues. The nature of the effects of genes on details of morphology is likely to remain very largely a matter for speculation alone, until some at least of these gaps are filled. Here perhaps we may leave a volume which contains many important contributions to botanical thought.

W. H. Pearsall

HARVEY ON MOVEMENT IN ANIMALS

De Motu Locali Animalium, 1627

By William Harvey. Edited, translated and introduced by Dr. Gweneth Whitteridge. Pp. xii+163. (Cambridge: At the University Press, 1959. Published for the Royal College of Physicians.) 60*s*. net.

SIR RUSSELL BRAIN was president of the Royal College of Physicians when plans were being evolved to mark the Tercentenary of Harvey's death. *Inter alia*, proposals were made to the College Library Committee at one or more of its meetings that Dr. Gweneth Whitteridge, who is archivist to Harvey's Hospital of St. Bartholomew in the City of London, should first transcribe and later translate and duly introduce his "De motu locali animalium", which forms *ff*. 69–118 of the British Museum manuscript Sloane 486. This was written throughout in Harvey's own hand, and consists of his notes on the anatomy of muscles (*ff*. 1–68), followed by his "local movement in animals". A title, "Guilielmus Harveius de musculis, motu locali etc.", written on *f*. 1 of the double manuscript, may have been added by Sir Hans Sloane. Anyhow, Harvey's rough draft for his intended book on the local movement of animals was begun in 1627, was mentioned in *Cap. xvii* of his "Exercitatio anatomica de motu cordis et sanguinis in animalibus", 1628, and was added to on several occasions, but was never cast into final literary form. The notes, which came to light in the British Museum in the middle of the nineteenth century, have never before been transcribed, but they make clear the tenor of Harvey's projected work on muscle and, though containing no new experimental observations, show that his understanding of muscle and muscular contraction was sounder than that of his predecessors and even of some of his successors.

The work has been published for the Royal College of Physicians at the Cambridge University Press, and has as an illustration a photograph of *f*. 95 of the manuscript under ultra-violet light, as evidence that such treatment has not revealed the presence of any writing which was not previously visible. The edition is limited to 1,000 copies.

Its chief concern has been to provide a text which is readable. The English version of "De motu locali animalium" is not to be taken as a literal translation of the Latin text, for it was decided against following Harvey's Latin literally and reproducing his notes in note form in English. The alternative method adopted was to follow the arguments alluded to by Harvey and to expand his notes into complete sentences by reading the books which he was following, and as closely as possible completing the thoughts which he, for his own reference, needed only to note down in a few words. Inevitably, this method has led to a certain amount of interpretation which may or may not be correct. The English version is therefore offered merely as a suggested rendering.

Dr. Whitteridge thanks the Librarian and staff of the Library of the University of Edinburgh, which has on its shelves several of the actual editions of the works used by Harvey. She also thanks her husband, Prof. David Whitteridge, for his discussion of physiological problems and for his help in writing about the importance of Harvey's 1627 treatise in the history of muscle physiology. She further expresses gratitude to Dr. Lorenzo Minio-Paluello for his encouragement to one who, before this, knew nothing of the natural philosophy of Aristotle.

There can be no doubt that Dr. Whitteridge has done consummately well in transcribing Harvey's obscure handwriting, translating his Latin, and annotating his notes; as Sir Russell Brain says, she has earned the gratitude and admiration of students of Harvey all over the world, not least among them being the President and Fellows of the Royal College of Physicians of London, at whose request she undertook the work.

Though Harvey's notes, as already stated, contain no great discovery, they have "much of interest to the student of his mind. They show him, as always, gathering his illustrations from every kind of animal and even plant life, and in addition recalling clinical observations which must have impressed him".

K. J. FRANKLIN

RECONSTRUCTING THE PAST

Life and Death in the Bronze Age

An Archæologist's Field-Work. By Sir Cyril Fox. Pp. xxvii+193+49 plates. (London: Routledge and Kegan Paul, Ltd., 1959.) 45*s*. net.

THIRTY years ago prehistorians were content to collect the relics left by early man, and to accept the view that little, if any, knowledge of the life he lived could be obtained—they were satisfied to produce the skeleton, but fearful of attempting to clothe it with flesh and blood. It is true that occasionally—as, for example, when discussing palæolithic ceremonial burials or when the cave art was under consideration—it did seem permissible to talk about ritual and magic, but by and large it was felt to be dangerous to attempt to picture prehistoric man as a living individual, even with the help of such a kindred study as ethnology. How could one be certain that similar conditions in times very different must have produced a similar outlook on life ?

For some time past, however, a new approach to the study of prehistoric man has been developing, leading to just that ground where the earlier investigators feared to tread. This new approach can be dangerous and result in grave errors, but not when it is pursued by such a master of the subject as is Sir Cyril Fox. There is no doubt that if a brilliant investigator has lived with his work for much of a lifetime he develops a sixth sense which enables small circumstances to be noticed which fall severally into place until the intuition becomes a well-nigh demonstrable fact. This is what makes any work by Fox so fascinating. Any good excavator can dig up prehistoric relics in a highly satisfactory manner using all the modern techniques; but it takes a Fox so to live with the builders of, say, a megalith he is investigating as to see them at their work of building and performing the ritual for which the monument was raised—and then to convey all this to his readers. Fox has another advantage over many of his contemporaries in that he remains so young. Often the later, post-retirement, works of a savant make sad reading, but this is not at all the case with the book under review. There is a freshness about it all, even when mere descriptions of excavations are being given, which is stimulating and delightful.

The period under consideration covers the millennium 1700 B.C.–700 B.C., and the excavations in question were mostly situated in Wales and were mainly the author's own work. The volume is splendidly illustrated with plans, line blocks and half-tones. The chapters are arranged geographically—north Wales, west Wales, west and south Wales, the 'Food-vessel' phase in Britain, barrows in Glamorgan, etc. To start with there is a long introduction to the subject. Here the problems of the Bronze Age in general and barrows in particular are discussed and distributions considered. The stage is thus set for the account of a round barrow in Ysceifiog parish, North Wales, and at once we are made to see what must have happened there in the past.

Sites in the other geographical areas are treated in the same manner and we are thus given a vivid picture of how and in what order the processes connected with barrow-building took place—facts of construction that, having been appreciated, have sometimes "formed a basis for the recovery of an elaborate ceremonial". The various finds—pottery, tools, and the like—are, of course, carefully noted and their parallels elsewhere discussed. The Welsh monuments are not treated *in vacuo*; the importance of their geographical position *vis-à-vis* Ireland is stressed. "Life and Death in the Bronze Age" is well worth careful study not only for the many facts brought to light but also, as has been already said, for the vivid picture it affords of happenings which must have taken place in a millennium of the British Bronze Age.

M. C. Burkitt

THE EARLIEST GEOLOGICAL TREATISE

The Earliest Geological Treatise (1667)

By Nicolaus Steno (Niels Stensen). Translated from "Canis Carchariae Dissectum Caput", with Introduction and Notes by Dr. Axel Garboe. Pp. v+51+4 plates. (London: Macmillan and Co., Ltd., 1958.) 15*s*. net.

MODERN geology as an inductive science was born in Italy in the latter part of the seventeenth century, the most famous of the pioneers being Nicolaus Steno (Niels Stensen, 1638–86), "the learned Dane", who had settled in Florence. In 1669 appeared his "De solido intra solidum naturaliter contento dissertationis prodromus" (the Prodromus to a dissertation concerning solids naturally contained within solids), the importance of which was recognized by Henry Oldenburg, secretary of the Royal Society, who published a translation (London, 1671).

Steno was led to study rocks through the examination of a shark's head which had been sent to him for dissection, and his account, "Canis Carchariae dissectum caput", published two years before the Prodromus, contains an appendix, which Dr. Garboe has translated, in which some of the essential elements of the later work are set down.

Recognizing the 'tongue stones' (*glossopetrae*) found in the rocks of Malta to be in all respects similar to the teeth of living sharks, he argues cogently that these and other fossils are the remains of once living aquatic animals, and he combats the view then commonly held that these bodies had grown within the rocks. This appendix consists of eleven 'observations' of sedimentary rock features, followed by six 'conjectures' in which the origins of the sediments, their fossils, cross-cutting veins, and departure from horizontality are deduced.

It seems strange to the geologist of to-day that the reaching of such fundamental and seemingly obvious conclusions was so long delayed, but their apparent conflict with the teachings of an all-powerful Church not only hindered the recognition of the significance of the evidence but also made men wary of voicing their opinions.

Dr. Axel Garboe is to be thanked for this page-by-page translation, which makes available to the English-speaking world "the earliest geological treatise". As frontispiece there is a reproduction of the portrait of Steno as a young man (Uffizi Gallery, Florence); also there is a copy of the title page of the 1667 work and its figure of a shark's head and teeth.

L. Hawkes

PRINTED CIRCUITS

The Technology of Printed Circuits

The Foil Technique in Electronic Production. By Dr. Paul Eisler. Pp. x+405. (London: Heywood and Co., Ltd., 1959.) 60*s*. net.

PRINTED circuits have been developed in the past decade for use in equipment ranging from electronic computers to aircraft de-icing systems, and continue to replace manual wiring. In conjunction with component insertion machines they enable high rates of production to be attained with low labour and inspection costs, and a greater uniformity of product than was possible by previous methods of wiring.

The book gives ample evidence of the author's position as a leading contributor to the technology of printed circuits, and the inventor of the printed foil technique now in general use.

The first two chapters describe early attempts at printed circuit production, and alternative methods such as spraying, stencilling, die-stamping and plating.

Chapters 3–8 contain a full account of the large-scale manufacture of printed circuit boards, including the photography of the master drawing, the preparation of the raw material, the printing processes, and etching and cleaning. Chapter 9 gives details of the subsequent operations such as the deposition of protective coatings, soldering and encapsulation.

Chapter 10 contains an excellent description of the small-scale production of printed circuits, and the laboratory apparatus required.

The following three chapters deal with the design of printed circuits, the selection of foil and insulating board, the choice of components, automatic assembly and fault finding.

The final chapters describe methods of reducing the weight and size of electronic equipment, the use of printed components, and the application of printed circuits to microwave systems and electronic devices. An excellent bibliography is included.

The wealth of practical detail given in the early chapters will be invaluable to those engaged in the manufacture and design of printed circuit assemblies, but the general reader would welcome more information about the use of printed circuits in various branches of the electrical industry, and their influence on system design, mechanical lay-out, and maintenance procedure.

However, this is the most comprehensive treatment of the subject generally available, and it is clearly destined to become the standard work of reference on printed circuit technology.

J. C. Cluley

BICENTENARY OF THE ROYAL BOTANIC GARDENS, KEW

By DR. W. B. TURRILL, O.B.E., F.R.S.
Formerly Keeper of the Herbarium and Library

THE choice of 1959 as the bicentenary of the Royal Botanic Gardens, Kew, is approximately a correct one so far as the present Gardens are concerned. There is at least one reference to a garden at Kew belonging to the Rev. William Turner (c. 1510–68), who has been termed 'the father of English botany'. Sir Henry Capel (?–1696) was also a notable cultivator of plants, but mainly from the horticultural rather than the botanical point of view. His property at Kew descended to a grand-niece, Lady Elizabeth Capel, who married Mr. Samuel Molyneux, a politician and secretary to the Prince of Wales (later George II). On the death of Molyneux's widow in 1730, the then Prince of Wales, Frederick Louis, obtained a lease of Kew House and laid out the grounds afresh. Frederick married the Princess Augusta of Saxe-Gotha in 1736 and died in 1751. The Princess Augusta, then Dowager Princess of Wales, continued to live at Kew, and about 1759, with the help and advice of John Stuart, third Earl of Bute (1713–92), who was sincerely interested in botany, laid out about nine acres of the grounds of Kew House as a botanic garden and appointed the architect, Sir William Chambers (1726–96), to embellish the garden and the adjacent pleasure grounds. Many of the buildings erected by Chambers have now disappeared, but several remain, of which the most noteworthy are the Orangery (1760–61) and the Pagoda (1761–62).

Perhaps the most important happening, from the practical point of view, of this period was the appointment in 1759 of William Aiton (1731–93) as superintendent of the botanic garden. Aiton was a botanist as well as a gardener, and in 1789 published his "Hortus Kewensis", or a "Catalogue of the Plants Cultivated in the Royal Botanic Garden, Kew". This work, in three volumes, includes 5,500 species which are named, often described, and classified according to the Linnean system.

Aiton, at first, had under his charge only the relatively small botanic garden of the Princess Augusta; but his responsibilities were increased more or less gradually, and in 1784 he took over the entire management of both the Royal Gardens of Kew and Richmond. William Aiton died in 1793 and was succeeded by his eldest son, William Townsend Aiton (1766–1849), who published a second edition of the "Hortus Kewensis" in five volumes.

While the Aitons were head gardeners, superintendents, or what would now be called curators of Kew, it was first to the Earl of Bute and later to Sir Joseph Banks that the development of Kew on the purely botanical side was very largely due. The former was unofficial director of Kew under the Princess Augusta. The deaths of his father and grandfather (George II) brought the Kew and adjacent Richmond properties into the ownership of George III, and in 1765 the King obtained powers from Parliament to close the public right of way, known as Love Lane, which separated the two "Gardens". Though the closure was not completed for some years, it was from this fusion of the gardens (botanic and pleasure) of Kew House and part of those of Richmond Lodge that the present title of Royal Botanic Gardens (in the plural) originated. George III, Queen Charlotte, and their family (fifteen sons and daughters) spent much time at Kew, where the King delighted to play the part of 'Farmer George'.

When the Princess Augusta died in 1772 her property came immediately and fully into the possession of George III, who replaced the Earl of Bute by Sir Joseph Banks as adviser on the botanical developments at Kew. Banks planned to grow species of plants from all parts of the world in the botanic garden. He sent trained collectors to many countries overseas, bombarded ministers and government officials with letters of instruction, sometimes almost of command, and gave freely of his time, energy, and money to this end. It is said that about seven thousand plants from abroad new to cultivation in England were thus introduced to Kew during the reign of George III. Among the 'Kew collectors' of this period were Francis Masson (1741–1806), who collected in South Africa, the West Indies and North America; David Nelson (died 1789), who visited Australia, South Africa and Timor; A. P. Hove, who was in India during 1787–89; Peter Good (died 1803), who sent plants from India and Australia; George Caley (died 1829), who went to Australia; William Ker (died 1841), an early collector in China; the brilliant botanist, Allan Cunningham (1791–1839), who collected widely in Brazil, South Africa, Australia and New Zealand; James Bowie (died 1869), who sent material from Brazil and South Africa; and David Lockhart (died 1846), who went to the Congo and, later, to Trinidad. Another collector who, through Sir Joseph Banks, made important contributions to the botanical development of Kew was Archibald Menzies (1754–1842), who was surgeon and botanist to Captain George Vancouver (1758–98) in his voyage of survey (1791–95) and sent plants from Australia, South America and western North America. He introduced the monkey puzzle (*Araucaria araucana*) from Chile to Kew and was the discoverer of the redwood (*Sequoia sempervirens*) in California.

George III and Sir Joseph Banks both died in 1820, and Kew passed into a period of relative decline. No more collectors were sent out from Kew, though seeds and plants continued to be received from overseas. That the Gardens did not die as a botanical institution was largely due to John Smith (1798–1888), who was made W. T. Aiton's chief assistant in 1826 and later, under Sir William Hooker, became curator. In January 1838 the Treasury appointed a committee "to inquire into the management, etc., of the Royal Gardens". This committee consisted of Dr. John Lindley, a renowned botanist and author of "The Vegetable Kingdom", Mr. (later Sir) Joseph Paxton, and a Mr. Wilson, gardener to the Earl of Surrey. The resulting report described the collections, then at Kew, their condition, the state of the greenhouses, etc., and was extremely critical, though the report was itself criticized by John Smith in his "Records". However, the report on the constructive side pointed out strongly the need for a well-managed and well-equipped botanic garden in Great Britain. It was presented to Parlia-

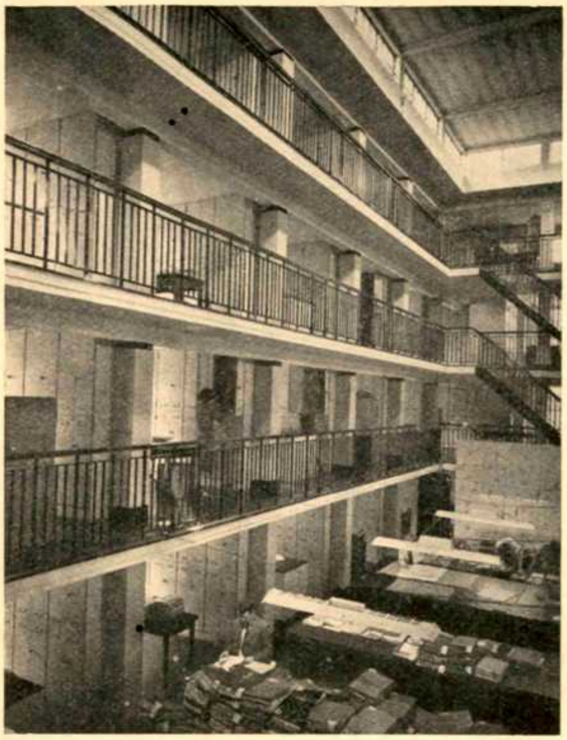

Fig. 1. Part of the Herbarium, Royal Botanic Gardens, Kew

ment on May 12, 1840, and as a result the control of Kew was transferred from the Lord Steward to the Commissioners of Woods and Forests, that is, from being the personal property of the Crown to the nation. Sir William Jackson Hooker, then regius professor of botany in the University of Glasgow, was appointed director in March 1841.

Kew as we know it to-day is very largely the creation of Sir William Hooker. Apart from being a first-class botanist, he was an organizer and administrator of the first rank. When he became the first director of Kew officially appointed by the Government, the garden area in his charge was only about 15 acres, and this was divided by brick walls which he speedily had pulled down. When he died, in 1865, six weeks past his eightieth birthday, Kew Gardens extended over 250 acres. Such figures, however, are only superficial indications of what Sir William did for Kew. New plants were received from many sources, a large part of the ground was laid out afresh, the Palm House was built between 1844 and 1848, the first Museum of Economic Botany was opened to the public in 1848, the Herbarium and Library were commenced in 1853, the Lake was completed in 1856, the first flagstaff successfully erected was presented in 1861, and the Temperate House was completed in 1862. Sir William continued his botanical and editorial activities, many of which had been started in Glasgow, after his appointment as director of Kew, and he encouraged botanical research by his staff and by visitors.

Sir William's only surviving son, Joseph Dalton Hooker (knighted in 1877), had been assistant director during 1855–65 and was appointed director in immediate succession to his father. He was born, as the second son, in 1817 and was educated in Glasgow. After taking his M.D., he was appointed assistant surgeon in the Royal Navy and was gazetted to the *Erebus* which, with the *Terror*, under the command of Captain (later Sir) James Ross, visited many parts of the southern hemisphere. J. D. Hooker's large collections were later worked out by him and published in a series of important volumes dealing with the taxonomy and phytogeography of the countries explored. From late 1847 until early 1851 he was in India and for three entire years explored and collected especially in Sikkim, eastern Nepal, and the Khasia Hills. His interest in Indian botany, which culminated in the preparation and publication of "The Flora of British India" (seven volumes, 1872–97), remained with him all his life. After his appointment as director of Kew, J. D. Hooker undertook two more botanical journeys, one to Morocco in 1871 and one to western North America in 1877. The most important taxonomic work was the "Genera Plantarum" (1862–83), written in collaboration with George Bentham and containing descriptions in Latin of all the then known families and genera of seed-bearing plants. These descriptions have, as a whole, never been excelled, and the volumes are still constantly used by taxonomists. Besides his own researches, J. D. Hooker encouraged much and diverse botanical investigation at Kew, particularly in taxonomy, plant geography, and economic botany. He made numerous improvements in the Gardens. Thus, he planted the Pinetum, brought the Berberis Dell to its present condition, created the Rock Garden, planted the Holly Walk, and improved avenues and vistas. The T-range was erected in 1868–69, the Jodrell Laboratory was built in 1876, a new wing was completed for the Herbarium in 1877, a wing added to Museum I in 1881, and the North Gallery opened to the public in 1882. After his retirement from the directorship in 1885, Sir Joseph Hooker lived at Sunningdale in Berkshire and continued to edit the "Icones Plantarum" until the end of 1889 and the *Botanical Magazine* until 1902 and for two years more with assistance. He completed the "Flora of British India", and during the final years of his long life continued researches in the genus *Impatiens*, results of which were published up to the year of his death, 1911. He was buried, with his father, in the family vault in St. Anne's Churchyard, Kew.

The history of Kew during 1841–85 is almost synonymous with the biographies, during that period, of the two Hookers, father and son. It gives some idea of their tremendous activities to record that in

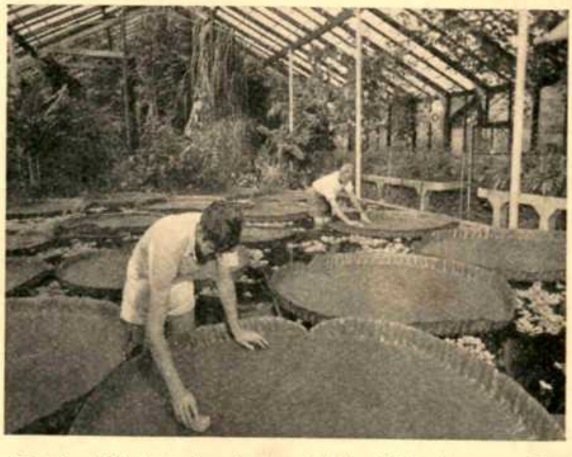

Fig. 2. *Victoria regia*, giant water-lily of the Amazon. The leaves attain a diameter of up to 6 ft.

the Kew Library there are 76 volumes (many large) of Hookerian correspondence. Administration had its difficulties, and the famous controversy in 1872 between the director and his official superior, the First Commissioner of Works, A. S. Ayrton, led to debates in both Houses of Parliament, the publication of a 'bluebook', and finally the placing of the authority of the director of Kew on a firmer basis.

J. D. Hooker was succeeded in the directorship by his son-in-law, William Turner Thiselton Dyer (the last two names became hyphened about 1891). Dyer was particularly keen on making Kew the botanical centre of the British Empire, especially as regards plant taxonomy and economic botany, and he did much in this direction by stimulating the preparation of Colonial floras. A new wing of the Herbarium was built in 1902, and the *Kew Bulletin of Miscellaneous Information* (afterwards the *Kew Bulletin*) was started in 1887. The original "Index Kewensis" was published in 1895. Improvements were made in the Gardens, and houses for alpine plants, filmy ferns and pitcher plants were erected. The Queen's Cottage Grounds were given in 1898 by Queen Victoria to Kew to commemorate her Diamond Jubilee, and Cambridge Cottage and its walled garden were added in 1904. On April 1, 1903, the Royal Botanic Gardens, Kew, were transferred from the Office of Works to the Board of Agriculture and Fisheries (now the Ministry of Agriculture, Fisheries and Food).

Thiselton-Dyer resigned in December 1905 and was succeeded by Lieut.-Col. David Prain, who steadily developed the scientific activities of Kew until 1922, in spite of setbacks during the First World War. Dr. A. W. (later Sir Arthur) Hill was director from 1922 until his tragic death in a riding accident in 1941. After a short interval, Prof. E. J. (later Sir Edward) Salisbury was appointed to the directorship and retired in 1956, and the present director is Dr. G. Taylor, formerly keeper of the Department of Botany, British Museum (Natural History). During the past fifty years, additions to Kew include a fine new wing to the Herbarium (built in 1931), enlargements to the Rock Gardens, the Sherman-Hoyt House for Succulents, a Chalk Garden, a Clematis Wall, a modern Australian House, and new accommodation for the Orchid Collection. Many of the greenhouses have been renovated or reconstructed since the Second World War, notably the Palm House. The old Orangery, designed by Sir William Chambers and erected in 1760–61 and long used as a museum for timber exhibits, etc., is being converted to serve again its original purpose.

Since 1841 the Royal Botanic Gardens, Kew, have been a government institution serving an international function—the advancement of botanical science. From the nature of botany, certain divisions of the subject can only be studied adequately at a large central institution, and it is these that are the special concern of Kew. In particular, the three branches of plant taxonomy, phytogeography, and economic botany require large collections of specimens, a first-class library and facilities for wide contacts overseas. Kew provides these conditions probably more adequately than any other institution in the world, both to members of the staff and to very many students from all countries who visit Kew for longer or shorter periods. In addition, a great deal of assistance is given to correspondents in answering a very large variety of questions, in providing material for research, and in loaning specimens to recognized botanical institutions. The work of Kew is not limited to the three branches of botany mentioned above, but it is even more essential to record that these branches themselves are considered at Kew along modern lines to include or to have contact with most of the specialized subdivisions of botany that are dealt with in other institutions. Of the large collections at Kew that are available for research one may mention the living plants in the Gardens, with more than 45,000 species, the Herbarium of dried specimens exceeding 6,000,000 sheets including more than 200,000 types, the sets of microscope slides at the Jodrell Laboratory, and the extensive series of samples of economic products (timbers, fibres, foods, drugs, etc.) in the museums.

The continued contribution of Kew to botanical research may be briefly indicated by reference to publications. The long series of floras produced at Kew include the "Flora Australiensis", the "Flora of British India", the "Flora of Tropical Africa", the "Flora Capensis", the "Flora of West Tropical Africa" (now being revised), and many smaller works. In course of preparation, and in part publication, are the "Flora of Tropical East Africa", the "Flora of Cyprus", the "Flora of Iraq" and (in collaboration) the "Flora Zambesiaca". Assistance is also being given in the preparation of the "Flora of Trinidad and Tobago" and the "Flora Malesiana". The *Kew Bulletin* is now published with three parts to an annual volume and contains papers, mostly by members of the staff, on a variety of botanical subjects. The "Index Kewensis", one of the most useful works to systematists concerned with vascular plants, is compiled at Kew and supplements are now published quinquennially. The "Icones Plantarum" consists of black-and-white figures, with descriptions and other information, of plants preserved in the Kew Herbarium, and is published by the Bentham–Moxon trustees in parts at intervals. The *Botanical Magazine*, the oldest botanical and one of the oldest scientific publications still continuing, was commenced in 1787 and has been connected with Kew for more than a century. It has coloured figures prepared from living plants grown at Kew or in other British gardens with accompanying text giving a full descriptive and general botanical account of the plants depicted. It is prepared at Kew and published by the Royal Horticultural Society as a biennial volume of four parts. In addition to the floras and periodicals enumerated, members of the Kew staff contribute scientific papers to many scientific journals and societies and have published various independent books on a wide range of subjects including taxonomy, plant anatomy, phytogeography, economic products, ecology, and genetics.

In this brief sketch of the history and functions of Kew emphasis has been placed on the botanical activities of the institution. The educational and recreational value to the public are also very considerable. The Gardens are interesting and beautiful at all seasons of the year, above all in the months of May and June. In 1958, a 'bad weather' year, the number of visitors passing through the turnstiles was 946,499, and though many of these came for a 'day's outing', a high proportion gained knowledge concerning the wealth of form, colour and behaviour of a great range of plant life and of the use of trees, shrubs, and herbs in man's economic and æsthetic life. Kew's contribution to the welfare of the nation, the Commonwealth, and the world cannot be precisely measured in monetary or any other terms, but it is certainly very great.

THE MECHANISM OF DETERGENCE

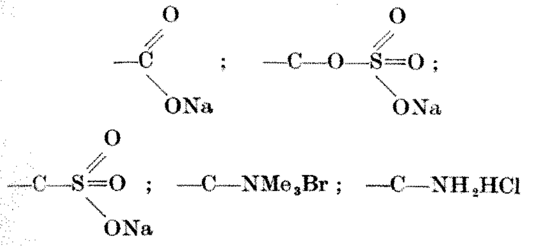
By Dr. A. S. C. LAWRENCE
Department of Chemistry, University of Sheffield

FOR nearly forty years since the discovery of orientated monomolecular films, detergent action has been described in terms of adsorption, wetting angles and reduction of surface free energy. Substrate and dirt have been regarded as inert non-polar surfaces on to which the soap is adsorbed with the hydrocarbon chain inwards and the polar group outwards to give wetting by water. As generalizations, the first is dubious and the second untrue. This general theory has no place for specificities of soaps for soils or substrates, nor can it explain the nature of the actual detachment and breaking up of dirts of sticky consistency and strongly adherent character. Indeed, some writers have been careful to say that there is no justification for saying that detergence is a spontaneous process. Nevertheless there is in the detergence of polar dirt a spontaneous process of penetration of soap and water into the dirt, followed by peptization. This process has nothing to do with surface forces, but results from cryoscopic forces and diffusion processes in the ternary soap/water/polar dirt system. This new picture of the mechanism of detergence arises from the following considerations.

It is now known that a large number of organic substances, especially fatty ones, are soluble in aqueous soap solution even though insoluble in water, and that substances partially miscible in water have their mutual solubilities greatly increased by addition of soap. By 'soap' I mean any substance which has the properties of soap; that is, a substance which in aqueous solution is surface active, froths, emulsifies oils and has detergent action: a definition which includes the substances variously described as synthetic detergents, syndets, surface-active agents, surfactants and even, in the horrible advertising jargon, 'soapless soaps'. Those most studied are of the type:

$$\underset{R_1}{\sim\sim\sim\sim\sim\sim\sim\sim}(S)$$

where R_1 is a saturated hydrocarbon chain of 12, 16 or 18 carbon atoms, and the oleyl soaps, which have a C_{18} chain with a double bond in the 9 : 10 position, and the *cis* configuration, which gives them solubility corresponding more nearly with the C_{12} saturated chain than the C_{18} chain. S represents:



$$-\overset{\overset{O}{/\!/}}{C}\!\underset{\underset{ONa}{\diagdown}}{} \;;\quad -C-O-\overset{\overset{O}{/\!/}}{S}\!=\!O\underset{\underset{ONa}{\diagdown}}{} \;;$$

$$-C-\overset{\overset{O}{/\!/}}{S}\!=\!O\underset{\underset{ONa}{\diagdown}}{} \;;\quad -C-NMe_3Br\;;\quad -C-NH_2HCl$$

I am not concerned now with non-ionic soaps, where the picture is more confused. The organic substances which we have studied most thoroughly are the aliphatic acids, alcohols, and amines, which may be written generally as:

$$\underset{R_2}{\sim\sim\sim\sim\sim\sim\sim\sim}(A)$$

A benzene ring can be included in the R_2 chain and more complex substances such as cholesterol show similar solubility effects. These are all substances of the type named by Winsor 'amphiphilic'[1]; that is, substances containing both a polar water-soluble group and a water-insoluble group of size sufficient to confer hydrophobic properties—a structure which ensures that the two parts of the molecule always have opposed solubility tendencies. Winsor includes the soaps in the amphiphilic class, but I prefer to keep them out of it and call them soaps.

Ternary Soap/Water/Amphiphile Systems

At first sight, the changes observed when an amphiphile is added to aqueous soap solutions of various concentrations seem quite irrational, and phase analysis appears to be impossible because of the very high viscosities encountered. Once, however, the presence of a ternary liquid crystalline phase existing over a wide range of concentrations was established[2], study of phase equilibria became possible, and the full triangular diagrams have shown a remarkable consistency independent of the nature and charge of S and A, or of R_1 and R_2 provided R_2 contains five or more normal carbon atoms (Fig. 1)[3-5]. The diagram consists essentially of five areas (Fig. 1); at the top, at high concentrations of soap, solid soap exists; at the bottom, below about 10 per cent soap, there are two liquids, sometimes as separate phases or, with higher values of R_2, as a system in which the aqueous isotropic phase is enclosed in membranes of liquid-crystalline phase and which defy mechanical separation. This is not an emulsion although it resembles one to casual visual inspection. At the water-rich corner, L_1 is isotropic solution; this is the region of McBain's 'solubilization'. At the corner rich in organic component another isotropic liquid, L_2, exists; this is not formed merely by turning the micelles in L_1

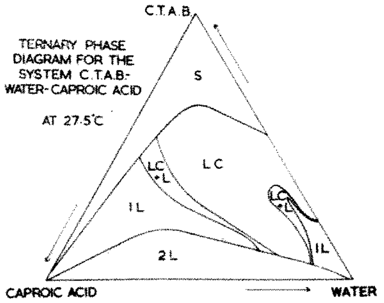


Fig. 1. Typical phase diagram for soap/water/amphiphile system. The diagram is for hexadecyltrimethylammonium bromide, water and hexanoic (caproic) acid at 27·5° C.

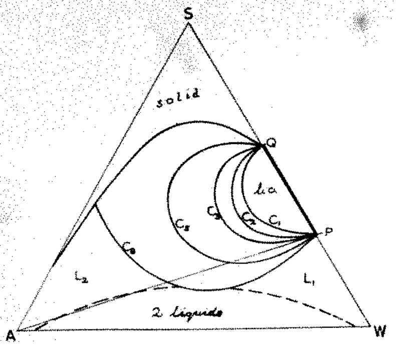

Fig. 2. Simplified diagram of the effect of chain-length of amphiphile (R_2) upon the phase boundaries of the ternary liquid-crystalline phase

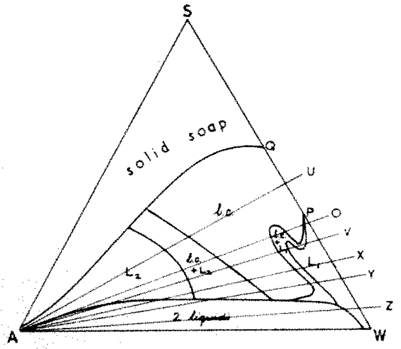

Fig. 3. Phase diagram for the system: sodium dodecyl sulphate/water/hexanoic (caproic) acid. Tie lines are shown to indicate the different sequences of changes when caproic acid is added to different initial concentrations of soap in water at 25° C.

inside out; they are reversed so as to become lipophilic in L_2 but, as they contain water, they are emulsions of truly colloidal dispersion[6], as opposed to the classical emulsions the dimensions of which place them far outside the range of true colloids. L_2 is the region of formation of the commercial 'soluble oils' when hydrocarbon is added as a fourth component. *LC* is the 100 per cent (smectic) liquid-crystalline phase flanked on either side by an area of $LC + L_1$ or L_2.

When R_2 is a 1, 2 or 3 carbon-atom chain or if the amphiphile is phenol or cresol, no two-liquid area occurs, L_1 and L_2 become continuous and extend to the base of the triangle. The liquid-crystalline (*l.c.*) phase, however, still exists as shown in Fig. 2. From this and from Fig. 1 it is clear that the *l.c.* area has, as base on the soap–water side of the triangle, the range of concentrations, *PQ*, over which the binary soap/water system is liquid-crystalline. This has been shown most clearly by Dervichian[7] in his potassium hexoate/water/methanol system; it is also clear why, starting from isotropic soap solutions, and adding the organic amphiphile, we do not observe liquid-crystalline phase when R_2 is a chain of less than five carbon atoms; the ternary liquid-crystalline phase exists but it is necessary to start with a soap solution which is already in the binary liquid-crystalline phase (tie line *AP*, Fig. 2 and *AU* in Fig. 3). If in Figs. 1, 2 and 3 we choose a concentration of soap in water and add amphiphile to it, we travel along a tie-line from that initial concentration to the 100 per cent amphiphile corner; the great variety of phase changes observed for initial soap concentrations of *U*, *V*, *X*, *Y* and *Z* are indicated in Fig. 3, which represents the phase diagram for sodium dodecyl-sulphate with caproic acid (amphiphile) and water. We see that we shall get different changes starting from concentration *V* of hexadecyltrimethylammonium bromide and of sodium dodecyl sulphate in Figs. 1 and 3. Again, if we wish to make a soluble-oil type such that no separation into two liquid phases occurs, then the minimum soap concentration is given by *AO*, the tie line from *A* tangential to the top of the two-liquid phase area.

This picture applies to all ionic soaps and amphiphiles regardless of the nature of the radicals *A* and *S* or of the sign of their charges. We have made a number of fatty alcohol/ethylene oxide-chain soaps which are interesting in so far as their solubility depends upon hydrogen bonding between the ethylene oxide chain and water. The aqueous solutions show a lower consolute temperature; that is, the soap and water separate into two liquid layers when the aqueous solution is heated. Addition of amphiphiles will lead to competition for hydrogen bonding and the case is different from that of ionic soaps. I suspect also that all these soaps are in fact true soaps solubilizing some of the lower water-insoluble polymers containing one, two or three ethylene oxide chains; the stepwise addition of ethylene oxide to form the polymer chain ensures that with an average number of, say, 6 ethylene oxide chains there must be some with more or some with fewer chains; the latter, together with any unreacted *R*OH, will therefore constitute amphiphiles already present in the soap solution, and extreme caution is necessary in interpreting the results of further deliberate addition of other amphiphiles.

Temperature Effects

With the higher homologues of the aliphatic amphiphiles, a lower temperature limit to the existence of the ternary liquid-crystalline phase is set by the point where the amphiphile crystallizes out; when this is present in excess, it freezes out at 2–3 deg. C. below its melting point. At more nearly equal ratios of soap and amphiphile, however, there is a large depression of freezing point such that the

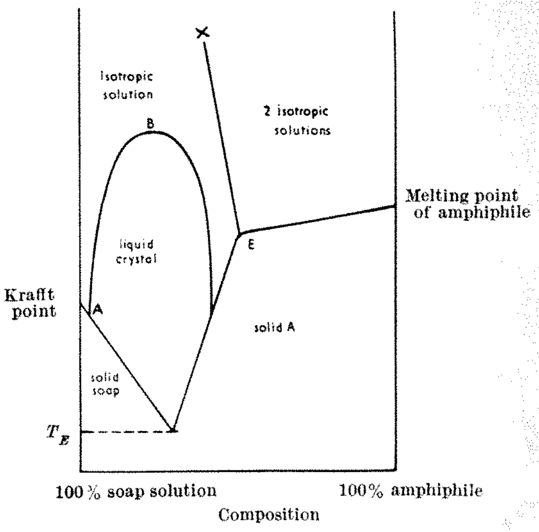

Fig. 4. Tentative temperature – composition diagram for soap/water/amphiphile systems for any selected soap–water concentration from the minimum required to avoid the two-liquid layer region up to the maximum at which the soap solution becomes liquid crystalline

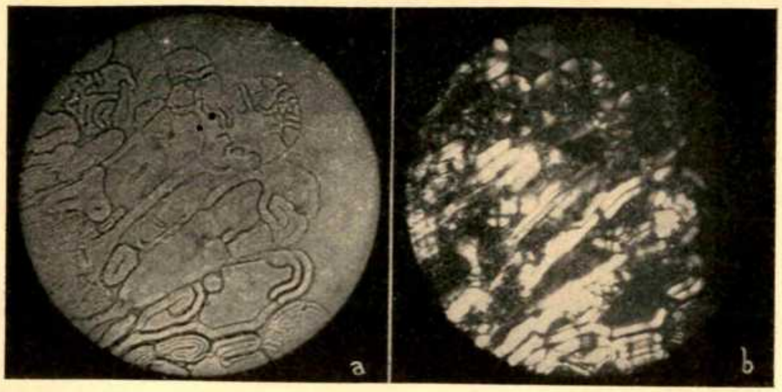

Nicols parallel (×50) Nicols crossed

Fig. 5. Myeline figures formed by penetration of water into an equimolecular mixture of sodium laurate and oleic acid; after about 10 min. at 20° C.

liquid-crystalline phase is stable at room temperature. Fig. 4 shows the temperature – composition diagram for such systems, treating them as binary mixtures with soap and water as one component and the amphiphile as the other; the Krafft point of the aqueous solution is taken as a melting point, while the other melting point is, of course, the orthodox one. It applies to all soap/water ratios between the minimum of about 10 per cent required to prevent formation of the lower two-liquid area and the upper limit at which the binary soap/water system becomes liquid crystalline. It will be seen that this is only a partial limitation involving the movement of the left-hand rising boundary of the *l.c.* phase from *A* to the $(S + W)$ axis; the low-temperature eutectic part of the diagram below the Krafft point being unaffected.

If the lower axis of the graph represents room temperature, then on the left we have solid soap plus solution; on the right, solid amphiphile plus solution; and in the centre ternary liquid-crystalline phase: this is found even with cholesterol as amphiphile which, in spite of its high melting point (147° C.), persists at 0° C. The upper temperature limit of the liquid-crystalline phase is usually above 100° C. The other cases in which either the melting point of the amphiphile or the Krafft point is below 0° C. have been described elsewhere[3]; also the case where both are below 0° C. and the first solid to separate out is ice.

Penetration Experiments

Fig. 4 suggests that the ternary liquid-crystalline phase should form spontaneously at room temperature by mixing the components. This can be shown to occur in two ways, both being observed most conveniently by the polarizing microscope. First, by placing a very small piece of soap plus amphiphile, as solid (or paste if the latter component is liquid), pressing a cover-glass down gently and then flooding with water. After 5–10 min., a crop of myelinic tubular forms is seen under a magnification of 50; they are best seen with the nicols parallel (Fig. 5*a*), although with crossed nicols the myelines are seen to be strongly birefringent close to the original material and becoming less and less so as they become more elongated. Finally, the outer part breaks up by dissolving to form an isotropic solution, L_1 (Fig. 5*b*).

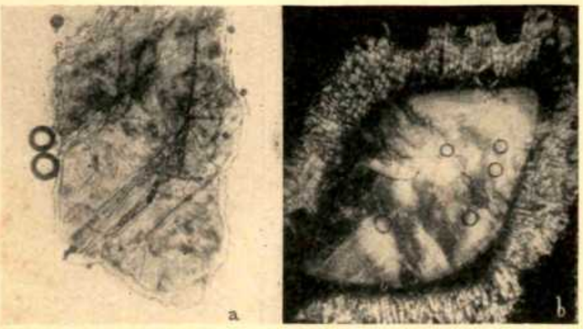

Fig. 6. Penetration of 15 per cent sodium dodecyl sulphate solution into solid stearic acid at 50° C.; (*a*) initial membrane in white light, and (*b*) after 6 min. in polarized light (× 20)

The second way is by immersing the solid amphiphile in soap solution; here also spontaneous formation of the ternary liquid-crystalline phase occurs but with two differences: the tubular myeline-like protuberances shown in Fig. 6 are sausages of liquid crystal and not tubular like the true myelines which have solution inside, and are elongated because the membrane containing them is a smectic liquid crystal with the axes of the long-chain molecules normal to the axis of the myeline so that extension can therefore take place only in a telescopic manner.

The second difference is that there is a sharply defined minimum temperature above which penetration of the soap solution into the solid amphiphile occurs (Fig. 7). Below this temperature (T_{pen}) only very slow formation of isotropic solution L_1 is

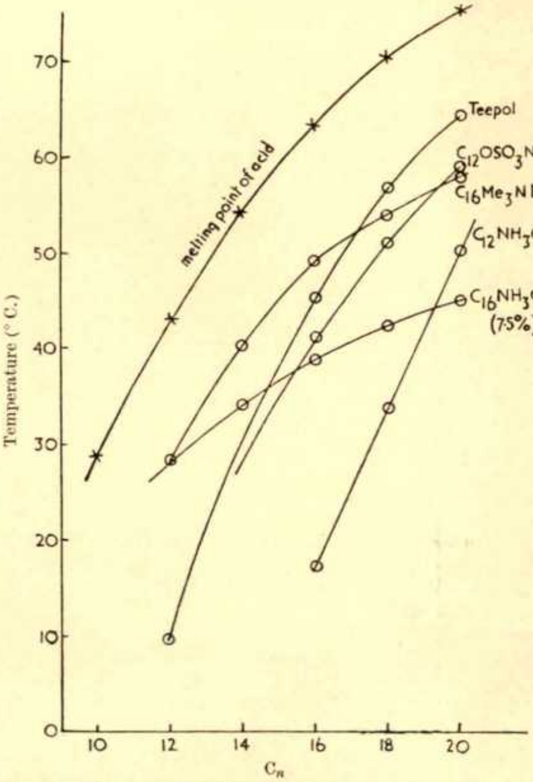

Fig. 7. Variation of temperature of penetration with chain-length for homologous fatty acids

observed. T_{pen} is several degrees below the melting point of the pure fatty amphiphile, and in the case of the eutectic curve of stearic and palmitic acids falls on a eutectoid curve with its minimum at the same composition but at a lower temperature (Fig. 8). Clearly T_{pen} should be identical with T_E, the eutectic temperature in Fig. 4. It is of interest in connexion with the ease of this penetration that the liquid crystalline growths are around the periphery of the crystal where polar groups are accessible and not on the large surfaces of the plates which are the terminal methyl groups.

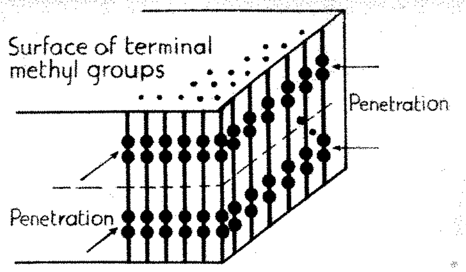

Fig. 9. Plate-shaped crystal of fatty amphiphile showing that the polar groups are accessible at the edges but not on the large flat faces of the plates

Detergence

It then occurred to me that these fatty amphiphiles are dirt—polar dirt it is true, but most dirt is partially polar—and that Fig. 7 is a picture of the spontaneous action of a detergent penetrating and peptizing dirt; that the triangular diagrams are soap/water/dirt phase diagrams and that Fig. 4 is the diagram of the temperature changes involved in detergence. Myeline formation has been reported in detergence by Stevenson[8] and also by Harker[9].

It may be objected that the process described requires a concentration of soap much larger than that normally used in detergence, but the objection is not valid because there will be a close-packed adsorbed monolayer of soap at the solution–dirt interface. At the point of attack the soap will always be a condensed phase and the interaction is of zero order with respect to the bulk concentration of soap. In fact, penetration occurs with solutions as dilute as 0·1 per cent.

Any line drawn from the solid stearic acid (shown in Fig. 6*b*) out into the isotropic solution is a tie line on the triangular phase diagram (perhaps not on a linear scale) from the 100 per cent amphiphile corner to the appropriate soap concentration; for example, *AO* in Fig. 3. We pass from solid amphiphile through fluid L_2 solution, very viscous *l.c.* into fluid L_1 solution; the dark isotropic ring around the stearic acid is the L_2 solution and, if the cover glass is disturbed, the *l.c.* phase is broken up, and floats away. Soap diffuses in again and builds up more *l.c.* and reduces the rate of diffusion of soap inwards. The gelatinous *l.c.* membrane is always separated from the 'dirt' by fluid L_2 phase; this is the reason why all washing requires agitation.

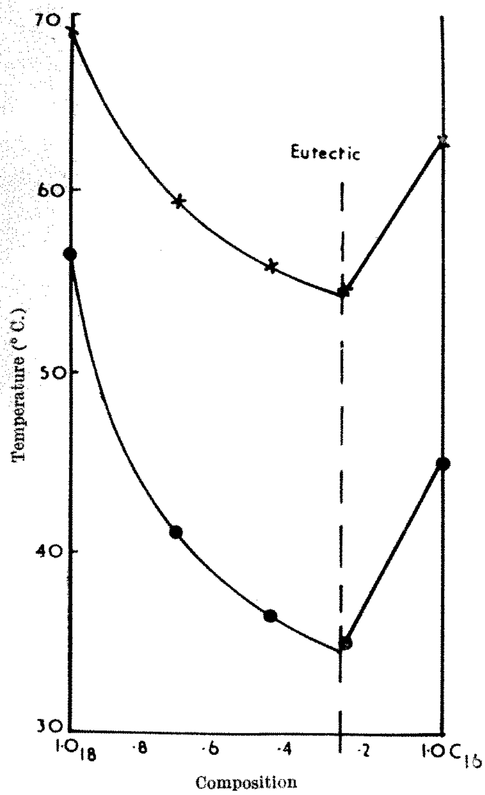

Fig. 8. T_{pen} for eutectic mixtures of stearic and palmitic acids; soap solution is 15 per cent sodium dodecyl sulphate

As described, fatty acids and alkanols are readily penetrated at temperatures greater than T_{pen}. Glycerin monolaurate was also penetrated but not the dilaurate. Addition of fatty acid or alcohol to 'Nujol' and paraffin wax showed that penetration in the former required a minimum concentration of about 10 per cent, whereas the wax needed at least 20 per cent.

An account has been presented of a mechanism of the process of detergence in terms of cryoscopic forces; the existing theory in terms of surface tension and free surface energy has always ignored this fundamental process. Wetting-angle phenomena are not affected by the new picture. Two outstanding problems, that of the very large temperature coefficient of efficiency of detergence and the rather mysterious one of 'redeposition', may well become explicable; the first as an increased rate of diffusion and the second by the fact that rinsing is a dilution so that we drop almost to the bottom of the ternary diagram into the two-liquid area, and, in this, the soap is in the organic phase: that is to say, the dirt is taking the soap out of the water.

The mechanism postulated here suggests that detergence is not brought about by free surface energy phenomena but by cryoscopic forces only. Ternary eutectic formation is by the water and the two water-soluble groups; the liquid crystalline properties result from the close-packing of the water-insoluble hydrocarbon 'tails' attached to the polar groups of soap and fatty soil.

I am indebted to Dr. T. Malkin for pure specimens of glycerin monolaurate and dilaurate.

DEVELOPMENTS IN PHOTOELASTICITY

COMMEMORATION AT UNIVERSITY COLLEGE, LONDON

A JUBILEE commemorative exhibition of photoelasticity has been held in University College, London. With a lecture delivered on April 15 by Colonel H. T. Jessop, special lecturer in photoelasticity in the College and sometime research assistant to Prof. L. N. G. Filon, it recorded the progress made in this method of stress exploration in the fifty years since its two most formidable protagonists, Profs. Coker and Filon, began their uneasy but extremely profitable partnership ; E. G. Coker was the Kennedy professor of engineering and L. N. G. Filon was the Goldsmid professor of applied mathematics in the College.

In 1909 Prof. Filon had been working for some years on the optical phenomenon of stress-induced birefringence, which had remained a laboratory curiosity since its original discovery by Brewster in 1816. While an undergraduate at University College, he had become interested, too, in the mathematical theory of elasticity as a result of his contact with Karl Pearson.

By 1909 Prof. Coker had also been attracted by the subject and his interest was that of a mathematically uninhibited engineer. He wanted to know the stresses in bodies for the purposes of design studies. He was introduced to photoelasticity by Silvanus Thompson and, in a four-year period of collaboration, these two men proposed a series of stress investigations using celluloid models of structures having engineering significance.

Coker seems to have been the first to realize the practical engineering significance of stress-induced birefringence, and his proposals precede similar work of Mesnager (who used glass) by three years. Coker's use of celluloid models was largely intuitive, and Filon pointed out the many theoretical questions that it begged. This brought the two men together, though no details are available of the first meeting in 1909. They clearly had very different approaches to the subject ; even so, their subsequent collaboration lasted until Coker's retirement twenty-seven years later. Furthermore, the text-book which bears their names has no equal, and is, for those interested in photoelasticity, what Love's treatise has been for elasticians.

The Exhibition of Apparatus

The early exhibits show the differing interests of these two pioneers. Filon's experiments and apparatus illustrate his concern with the optical behaviour of materials, and in particular glass, under simple and calculable states of stress. Coker's apparatus shows how he wanted the practical answers that could be obtained from each experiment, and he seems to have taken it as axiomatic that the elastic stresses—and in particular the maximum values of stress—were the significant quantities. Coker concerned himself with the purely two-dimensional problem of photoelasticity with three unknown quantities at each point. For his purposes, the directions of the principal stresses were obtained from isoclinics in a plane polariscope, the difference between the two principal stresses was deduced from the isochromatics in a circular polariscope, and their sum was found by the measurement of lateral strains. To this limited extent Coker could have claimed that he had completely 'solved' the problem of two-dimensional photoelasticity—indeed, the claim has often been made for him.

Filon seems to have distrusted the lateral strain measurements, although he verified their validity for a state of 'generalized plane stress'. He relied instead on the differential equation of equilibrium to give him the extra information which permitted the principal stresses to be separated. But for Filon's approach, the measurements which could be taken were not sufficiently accurate to justify calculation of their derivatives. This led him to consideration of stress trajectories which gave a curvilinear coordinate system, from which the so-called Lamé–Maxwell equations could be obtained. The errors of calculation were then mainly included in a single estimate of a radius of curvature.

Only a few pieces of Filon's apparatus survived the bombing in the Second World War. His first experiment on a glass beam in bending still exists, but the rest of the original apparatus has been lost. Two of his early experiments on dispersion and a calibration experiment on glass have been reassembled by Colonel Jessop, who was Filon's research assistant when the experiments were performed. Many of Coker's ingenious loading rigs and other pieces of his apparatus still exist. They illustrate his interest in stressed bodies of complex shape which, while they are far removed from mathematical abstraction, are common in engineering practice.

Not only were 'museum pieces' displayed ; the exhibition also gave an idea of the progress of the photoelastic method in recent years. The exhibits of recent origin revealed the amazing degree of confidence which is now placed both in model-making and in subsequent stress exploration. In fact, the method has been applied (both at University College and elsewhere) to structures of a complexity that would have surprised Prof. Coker, even in his most optimistic moments.

Recent Developments

During the Second World War, the laboratories of Profs. Coker and Filon disappeared, one literally (as a result of bombing), the other figuratively as a consequence of the rigours of war-time academic life. The revival of interest in photoelasticity in University College since then owes much to the support and encouragement of Prof. H. J. Collins and to the zeal of Colonel Jessop.

Both Coker and Filon appear to have believed that their exploitation of photoelasticity was more or less complete. But here, for once, they were quite wrong, and it is, perhaps, of interest to consider why this is so. The most striking advance has been made in three-dimensional work. This extension has been made possible by several factors. Of these, the development of a really suitable synthetic resin is a logical extension of Coker's step from glass to celluloid. With the appearance of modern epoxy casting resins, and in particular of 'Araldite *B*', practical materials have become available in adequate sizes; they possess good elastic behaviours, negligible creep, and sufficient optical sensitivity to be useful. With these new materials has come the stress-freezing technique—now more than twenty years old; this opens up an almost foolproof method for the analysis of solid models. By subjecting a model to a heating and loading cycle, it can be persuaded to 'remember' its loading system, and to retain an optical pattern which is equivalent to an elastic system of stress. The solid model can then be sectioned without disturbance of the optical effect, and a three-dimensional analysis can be made. The possibility of doing this was noted in Germany in 1935, but was apparently not known to Filon or to Coker (who was, by then, a sick man). A similar effect had been noted in glass at University College by Dr. F. C. Harris, although its implications for three-dimensional work were not recognized.

It is interesting to note that, with this development, one returns to the original difficulties of measurement which faced Coker. However, his primitive methods have been superseded by the techniques due to Tardy or Sénarmont. Sufficiently accurate measurements can now be made with strains in the model which are not more than ten times the strain in the prototype.

The interpretation of the results found from a model in terms of the corresponding full-scale structure in a different elastic material, and the effect of a tenfold increase in magnitude of strain in the model, was discussed in a review of the present state of knowledge. This was given at University College in two lectures on modern aspects of photoelasticity by Mr. C. Snell. He argued that although the position is not entirely clear, there are good theoretical and experimental reasons for transferring the stress pattern without significant change from model to prototype.

The problem of thermal stressing was exemplified in the exhibition, and the experimental difficulties that have yet to be overcome were mentioned. Dynamic stressing was also illustrated, with a demonstration that problems of dynamic elasticity can sometimes be studied by photoelastic means. In particular, periodic excitation can be investigated in this way unless the periodic time is too short for stroboscopic techniques to be adequate.

The use of optically sensitive layers to show the strain patterns in metals beyond the elastic range is probably the most recent development in photoelasticity. This technique was illustrated in two exhibits and is undoubtedly a promising new departure. Perhaps not so promising—but by no means without interest—was some apparatus (of recent origin) for investigating the optical behaviour of a moving fluid.

Photoelasticity in Engineering

These, and many other, exhibits leave no doubt about the future of photoelasticity. It has been put to use time and time again, particularly in the aircraft industry, where the economical use of material is vitally important. Now it seems clear that the methods will be widely employed in design work on nuclear engineering projects.

Historically, our knowledge of the stress–optical effect is of Scottish origin, the earliest investigations having been made by Brewster and, later, Maxwell. But practical stress exploration undoubtedly grew up in University College, London. It is most unlikely that any other institution could arrange, from its own resources, an exhibition covering so wide a range of productive work within photoelasticity—even if the earlier exhibits of purely historical interest are disregarded. This is a direct outcome of the collaboration of Profs. Coker and Filon—an engineer and a mathematician—and of the subsequent efforts of a small group of workers under the leadership of Colonel Jessop and, since his retirement, Mr. Snell.

R. E. D. BISHOP

OBITUARIES

Dr. Paul Chabanaud

DR. PAUL CHABANAUD, Chevalier de la Légion d'Honneur, well known for his researches on fishes, died on February 27 at the age of eighty-two.

Although he had been from childhood a keen amateur naturalist, Chabanaud began by preparing himself for a career in the law, but he considered this to have been a false start. Soon after the beginning of the First World War he was declared medically unfit for the Armed Forces and became a voluntary assistant to Prof. Roule at the Museum of Natural History in Paris, classifying and preparing exhibits from the collections of reptiles and amphibians.

In September 1919, Chabanaud received the blessing of the professors of the Museum to fulfil his great ambition of a collecting trip to tropical West Africa. Apart from free passage to French Guinea and free rail travel within the territory, the only financial assistance he received was a grant of ten or twelve hundred francs. He spent about eight months in the field, covering about 1,200 km. on foot, and brought back valuable collections of arthropods, reptiles, amphibians and fishes, as well as considerable ethnological material.

It was only on his return from this voyage that Chabanaud sought any remuneration for his scientific work, and in 1920 he was appointed Préparateur à l'École des Hautes Études, working in the Laboratoires des Pêches et Productions Coloniales d'Origine Animale. From this time his main studies were in ichthyology, and it was in this field that in 1936 he obtained his doctorate, with a thesis on the morphology and phylogeny of the flatfishes (Heterosomata). This penetrating study confirmed the groupings recognized by Tate Regan in 1910 and 1929, and demonstrated a better understanding of the details of flatfish structure than had been possessed by any of his predecessors. His interpretation of this classification, however, was unique. He agreed with Tate Regan that *Psettodes* was a little-modified percoid fish, diverging less from the symmetrical form than any other flatfish. But whereas Tate

Regan looked upon this genus as a survival from the base of the flatfish stem, to Chabanaud it was the latest departure from the path of percoid symmetry, and the more specialized soles and flounders were the modern twigs of earlier asymmetrical branches of the pre-percoid trunk. The fossils so far do not help to resolve this difference, for as Chabanaud himself was to describe, the main groups were already differentiated in the Upper Eocene.

The majority of Chabanaud's numerous publications after 1936 were on details of the morphology and classification of these asymmetrical fishes, in which he found an endless fascination. He applied to them a terminology of his own, which, in spite of its logical classicism, is unlikely to supersede current usage, which has 'just growed'. It was his ambition to write the second volume of the monograph of the flatfishes begun by J. R. Norman, but he began too late in life to analyse the many samples of soles and tongue-soles available to him and never arrived at a satisfactory synthesis.

Up to the eve of his last illness, Chabanaud would leave his flat in the Rue des Écoles at 8 a.m. and walk, painfully of late, to the laboratory in the Rue Cuvier to count more fin-rays and scales and cover more sheets with his endless tables. How I wish that in some Elysium it might be given him to draw from them the crystal truths that he was sure they would eventually yield ! He could be a charming host, and one of his most engaging accomplishments was the relating of reminiscences, plunging into parenthesis after parenthesis without faltering in the elegant use of his mother-tongue and never failing to emerge triumphantly in the end as from a series of Chinese puzzle-boxes.

He was quite unworldly, a man of child-like integrity and innocence of mind. He is survived by his second wife, with whom he spent many years of mutual devotion.

E. TREWAVAS

Prof. J. T. MacGregor-Morris

PROF. J. T. MACGREGOR-MORRIS died on March 18, at the age of eighty-seven. He established the Electrical Engineering Department at East London College (now Queen Mary College) in 1898, and he became the first professor of electrical engineering in this College, a position which he held until he retired in 1938.

He received his education in electrical engineering at University College, London, and, for a time, was personal assistant to Sir Ambrose Fleming. He was keenly interested in research and during the Second World War he did notable work in developing a hydrophone for submarine detection.

An important contribution to electrical engineering education by Prof. MacGregor-Morris was the manner in which during the lean years immediately following the First World War he kept research work alive in his department, despite meagre equipment and small research funds. He kept the department open on three evenings a week, and he inspired and directed the research work of students who attended on these evenings. The students were of good calibre and they did good work. Several of them have risen to important positions in the electrical industry.

Under the leadership of its professor, the Department grew steadily in prestige, and its housing and equipment improved as the years passed. A notable development was the opening of its well-known High Voltage Laboratory in 1938 with the aid of a grant from the London County Council. This Laboratory was an example of Prof. MacGregor-Morris's foresight —he was a good judge of new developments which were likely to become of major importance in electrical engineering. Another example of this was his interest in the cathode-ray tube from its earliest days. He was joint author of one of the earliest text-books dealing with these tubes.

His lectures were interesting, stimulating and unorthodox with his over-riding interest in research always intruding.

His students and particularly his research students were important personages to him. Many of them will recall with pleasure the annual 'get-together' of staff and research students at his home in Hampstead. Mrs. MacGregor-Morris always took an active part on these occasions.

He was a very active man. On most Wednesday afternoons during term time he would play a strenuous game of tennis or badminton. He was keenly interested in music and, when quite elderly, he learned to play the 'cello and became a proficient performer on this instrument. He was a devout Christian and took an active interest in missionary work.

W. J. JOHN

Dr. John Henderson, C.B.E.

DR. JOHN HENDERSON, for seventeen years director of the New Zealand Geological Survey (N.Z. Department of Scientific and Industrial Research), died suddenly at his home on March 6. Born in Dunedin in 1880, his later education was carried out at Otago Boys' High School, then at the University of Otago and Otago School of Mines. Here he completed, in 1902, his M.A. associateship of the School and B.E. (Mining).

For the next eight years he was director of Reefton School of Mines, during which time he devoted much energy to the investigation of the geological structure of the coal and gold mines of Westland and West Nelson, his thesis on the subject gaining him his D.Sc. in 1907.

In 1911 he was appointed mining geologist to the New Zealand Geological Survey. As well as keeping in touch with mining activities in the succeeding years, and reporting on numerous mines, quarries, and mineral properties of different kinds, he also reported on the geological implications of many engineering projects, for example the Arapuni Hydro-electric Dam on the Waikato River. In addition, he carried out extensive regional surveys of the geology and mineral resources of several districts. His bulletins on Reefton, Te Aroha (with J. A. Bartrum), Gisborne and Whatatutu (with M. Ongley), Mokau (with M. Ongley) and Huntly-Kawhia (with L. I. Grange) stand as lasting contributions to the geology of the Dominion.

At the request of the Fiji Government in 1923, Dr. Henderson visited and reported on the geology and mining prospects of gold-bearing quartz lodes in Vanua Levu.

Dr. Henderson, in 1928, succeeded the late P. G. Morgan as director of New Zealand Geological Survey and almost immediately encountered all the administrative difficulties and frustrations resulting from the financial stringency of the great economic depression. Nevertheless, by unremitting work he was able to keep his staff of geologists intact, and so actively to maintain the geological effort of New Zealand. Bulletins could no longer be printed, but the condensed reports, and the black-and-white geological maps of the annual reports of those years, have since proved their worth.

With the coming of better times and the greatly increased activities of Works, Railways and other Government Departments and public bodies, the requests for geological advice increased enormously. The consequent expansion of the Geological Survey was carried out over a wide field, including soil surveys and geophysical surveys. Each of these has now become a separate division of the Department of Scientific and Industrial Research. About this time Dr. Henderson represented the Dominion at the International Geological Congress in South Africa, when he was able to visit the great gold mines of Johannesburg and the Rand.

In addition to his official duties, Dr. Henderson wrote a number of papers on general geology and stratigraphy, published in the *Transactions of the Royal Society of New Zealand* and in the *N.Z. Journal of Science and Technology*. During his directorship he carried on the high tradition, so well implanted in Geological Survey routine by P. G. Morgan, of most careful and accurate editing of publications, especially of the bulletins. After retirement he acted as honorary editor (1946–49) of the *Transactions of the Royal Society of New Zealand*.

Dr. Henderson was of a modest and retiring disposition, avoiding publicity, but with a deep sense of public responsibility. His interests, and also his reading, covered a wide field. This gave him a vast amount of documented information always willingly and helpfully at the service of his colleagues. To the young geologist his wealth of knowledge and kindly interest provided a real source of inspiration.

Dr. Henderson was awarded, in 1929, the fellowship of the Royal Society of New Zealand, in 1935 the Jubilee Medal, in 1945 the Hector Medal and Award of the Royal Society of New Zealand, and in 1948 he was appointed C.B.E. J. Marwick

NEWS and VIEWS

New Foreign Members of the Royal Society : Prof. Melvin Calvin

Prof. Melvin Calvin, of the University of California, Berkeley, California, whose election to the foreign membership of the Royal Society was recently announced (see *Nature*, **183**, 1230 ; 1959), started his professional career as a control chemist in industry after the completion of his doctorate at the University of Minnesota, to which he later returned as a teaching Fellow. He then spent two years at the University of Manchester, returning in 1937 to the University of California, where he has remained ever since. His early interests were in theoretical organic chemistry and the mechanism of organic reactions.

After the Second World War Calvin took over the work initiated by Ruben on the study of photosynthesis, but employing the newly available radioisotope, carbon-14. The early results were questioned by many biologists, who from their physiological studies held strong convictions about the probable mechanism of photosynthesis ; but with the timely advent of paper chromatographic methods Calvin used these to exploit the powerful potentialities of tracer techniques. From then on progress was rapid and Calvin was gradually led to formulate a mechanism of carbon reduction in photosynthesis which is now universally accepted. From studies of photosynthesis he was led to postulate enzymic systems not then isolated but afterwards discovered both in animal and in plant tissues. The photosynthetic cycle of Calvin and his collaborators may be elaborated in the future but is unlikely to be changed in its essential features. He was awarded the Stephen Hales award of the American Society of Plant Physiologists in 1956.

The Editors regret that, due to difficulties in the printing industry, some sections of this issue of "Nature" have had to be curtailed

Calvin is the co-author of an excellent text-book on theoretical organic chemistry and his lectures have stimulated both undergraduates and research workers. He has published books on the use of isotopes and on the chemistry of metal chelate compounds. His wide interests include photochemistry and general physical chemistry as well as theoretical organic chemistry.

Prof. G. Domagk

Prof. Gerhard Domagk, recently elected a foreign member of the Royal Society, has devoted his life to the fight against some of the main scourges on mankind, against cancer and against bacterial infections including tuberculosis. A graduate of the University of Kiel, Domagk began his university career in Greifswald and Münster ; in 1927 he became head of the Research Institute for Experimental Pathology and Bacteriology of I. G. Farbenindustrie, Elberfeld, and it is there that he has carried out his successful researches for more than thirty years. Throughout this period he has, however, kept his ties with the University of Münster, where he was made personal professor in 1932.

His discovery in 1932 that an azo dye, 'prontosil', cured streptococcal infections in mice revolutionized medical thought, which had for many years proclaimed that chemotherapy of bacterial, in contrast to chemotherapy of protozoan, diseases was a utopian aim. It is well known how this discovery led to the development of the treatment of many serious infections with a variety of 'sulphonamides' ; the award of the Nobel Prize in 1939 was in recognition of this very great advance.

It is a tribute to the impetus given to chemotherapy by Domagk's discovery that when he turned to the problem of the chemotherapy of tuberculosis, there were many groups all over the world trying to tackle the same problem. So it happened that Domagk's most successful anti-tuberculous drug, isoniazid, discovered by him in 1951, was introduced into therapy independently by a group of American workers. Domagk was also the first to direct attention to the important antiseptic properties of the so-called 'inverted soaps'.

Domagk, whose interest in cancer dates back to 1928, is now mainly interested in the possibilities of chemotherapy of cancer. As a result of his recent work on animals, some compounds of promise are at present undergoing clinical trial. For the sake of mankind it is to be hoped that the success he has had in his other fields of endeavour will not fail him in this quest.

Prof. J. H. Oort

FEW astronomers have made such important contributions to the study of the structure and dynamics of the galactic system as Prof. J. H. Oort, who was recently elected to foreign membership of the Royal Society. He was among the first to recognize the importance of the high-velocity stars, interpreting the zone of avoidance of their motions in terms of the velocity of escape from the galactic system. These studies enabled him to develop Lindblad's theory of galactic rotation into the form in which it is used to-day. He developed formulæ for the effect of galactic rotation on the radial velocities and proper motions of the stars, and analysed the observational material to obtain estimates of the angular velocity and mass of the Galaxy. Another major investigation was concerned with the motions of the stars perpendicular to the galactic plane. Oort obtained a relation between the velocities of the stars and the gravitational acceleration of the Galaxy, and with the aid of models of the Galaxy he determined the density of matter in the solar neighbourhood. Since the Second World War, Oort's most important work has been his inspiration and leadership of the team of Dutch astronomers who have been investigating galactic structure with the aid of 21-cm. hydrogen radiation. It is no exaggeration to say that, under Oort's direction, the Leyden Observatory has become one of the world's leading astronomical institutions, the work of which has had, and continues to have, a profound influence on the progress of astronomy.

Prof. A. H. T. Theorell

PROF. HUGO THEORELL was also recently elected a foreign member of the Royal Society. Theorell's main work at the Nobel Medical Institute, Stockholm, has been concerned with the oxidizing enzymes, especially flavoproteins, hæmoproteins and dehydrogenases, in all of which fields he has made important contributions to knowledge during a period of more than twenty-five years. He first purified the yeast flavoprotein which had been discovered by Warburg and Christian, and later he isolated it in crystalline form. He investigated particularly the nature of the union between the flavin prosthetic group and the protein part, and showed the importance of the phosphate group in this. He also was the first to crystallize several hæmoproteins, including myoglobin and the peroxidases of milk and horseradish, and studied them in detail by physical methods, developing especially the use of measurements of magnetic susceptibility for the examination of the state of the iron atom in hæmoproteins. Theorell also investigated in great detail the structure of highly purified cytochrome *c*, established that the connexion of the porphyrin with the protein was through sulphur groups, and was ultimately able to construct a model of the structure of the part of the molecule adjoining the prosthetic group. He also carried out an important detailed study of the kinetics of the alcohol dehydrogenase system, using elegant methods depending on measurements of ultra-violet absorption and fluorescence. This led to interpretations of the apparent Michaelis constants of the various reactants in terms of the rate constants of the separate steps of the catalytic process and threw a good deal of light on the mechanism of the catalytic action of the enzyme.

Institution of Mining and Metallurgy: Awards

THE Institution of Mining and Metallurgy has announced the following awards: The Gold Medal of the Institution for 1958 to Dr. A. J. Orenstein, for long and distinguished service in the cause of the health and welfare of the workers in the mining industry, with particular reference to the Witwatersrand; honorary membership of the Institution has been conferred on Mr. W. A. C. Newman, in recognition of his services both to the Institution (of which he is a past-president) and to metallurgical education; on Brig. R. S. G. Stokes, past-president, in recognition of his services to the mining industry particularly in South Africa; and on Sir Alexander Fleck, in recognition of his outstanding services to the metallurgical industry; 'The Consolidated Gold Fields of South Africa, Limited' Gold Medal for the session 1957–58, to Mr. F. A. Williams, for his paper entitled "Performance Analyses of Screens, Hydrocyclones, Jigs and Tables used in recovering Heavy Accessory Minerals from an intensely decomposed Granite on the Jos Plateau, Nigeria" (*Trans. Inst. Min. Metall.*, **67**); and 'The Consolidated Gold Fields of South Africa, Limited' Premium of forty guineas for 1957–58, jointly to Mr. H. H. Fraser and Mr. O. E. A. Somerset, for their paper entitled "Scientific Management Principles applied to West African Mining" (*Trans. Inst. Min. Metall.*, **67**); The 'William Frecheville' Student's Prize to Mr. I. R. M. Chaston, for his paper entitled "A Simple Formula for Calculating the Approximate Capacity of a Hydrocyclone" (*Trans. Inst. Min. Metall.*, **67**).

Leverhulme Research Awards, 1959

THE Trustees have approved, among others, the following research fellowships and grants tenable for periods up to two years. *Fellowship:* Dr. K. R. S. Morris (epidemiologist attached to the American Foundation for Tropical Medicine, Inc., Harbel, Liberia) for a historical and epidemiological study of the movement of sleeping sickness across Africa. *Research grants:* Maurice Black (fellow and director of studies, Trinity College, University of Cambridge) to complete a study of limestone deposition in the Bahama Islands; Geoffrey Bownas (lecturer in Chinese and Japanese studies, University of Oxford) for a comparative study of urban and rural life in Shiga Prefecture, Japan; Dr. N. H. Hartshorne (reader in chemical microscopy, University of Leeds) for a critical study of the applications of polarization microscopy in chemical and biological research and practice; Dr. K. J. Ivin (lecturer in physical chemistry, University of Leeds) to study the solution properties of polymers; G. G. Lemon (lecturer in petrology and economic geology, University College of Wales, Cardiff) to study the metamorphic rocks of the County Sligo area, Eire; Mrs. Lily Newton (lately professor of botany, University College of Wales, Aberystwyth) to study marine algae, especially those with walls yielding carrageenin and algin; D. T. Whiteside (St. Catharine's College, University of Cambridge) for an examination of the mathematical section of the Portsmouth Collection of Newton manuscripts.

A Lunar Radio Communication Link across the Atlantic

IN a series of experiments carried out between May 11 and May 14 a lunar radio communication link was successfully established between the Jodrell Bank Experimental Station in Cheshire and the Air Force Cambridge Research Center at Bedford, Massachusetts. A 1-kW. frequency-modulated transmitter working on 201·00 Mc./s. was used with the 250-ft. steerable radio telescope at Jodrell Bank. In the United States an 84-ft. radio telescope was used with receivers of various bandwidths from ± 2·5 to ± 10 kc./s. Similar receivers were also used on the telescope at Jodrell Bank for monitoring the local lunar returns. The aerial systems were circularly polarized in order to avoid the deep fading caused by Faraday rotation in the ionosphere. A series of experiments lasting for about 40 hr. included the study of the transmission of audio tones up to 15 kc./s., the transmission of messages by slow Morse, and tests of the intelligibility of speech and quality of music. The tones and Morse were received in the United States without difficulty. Speech as received back at Jodrell Bank was nearly always clear and intelligible, but only occasionally so in America because of the low signal-to-noise ratio of their equipment.

Although trans-Atlantic reception of the lunar radar pulses transmitted from Jodrell Bank was reported in 1958, the recent experiments are believed to be the first to demonstrate the feasibility of a true lunar communication link. The commercial interest in long-distance transmission secure from ionospheric and terrestrial interference will undoubtedly stimulate further developments in this field. Transmitters of somewhat greater power working in the microwave band, where the potentialities of low-noise maser or parametric receivers can be realized, should enable the size of the radio telescopes to be reduced, and at the same time provide sufficient signal-strength to ensure speech intelligibility under all conditions. This work was carried out as part of a joint programme between Jodrell Bank and the Air Force Cambridge Research Center, but the early realization of the successful lunar link was made possible by the interest of Pye Telecommunications, Ltd., which provided the transmitter and receivers.

Creation of the College of Technologists

THE establishment of the College of Technologists was announced on May 20 by the Governing Body of the National Council for Technological Awards, the chairman of which is Lord Hives. The College will administer the award of Membership of the College of Technologists (M.C.T.) which the National Council proposes to create as a qualification higher than the Diploma in Technology. The College of Technologists will operate within the framework of the National Council for Technological Awards and will be served by the same administrative staff. A Board of Scientific and Industrial Studies is to be responsible for the academic and industrial aspects of the administration of the award. The governing body of the National Council has met as the Court of the College and the following appointments to the Board were made: Sir Arnold Hall, managing director, Bristol Siddeley Engines, Ltd. (*chairman*); Mr. A. W. J. Chisholm (head of the Department of Mechanical Engineering, Royal Technical College, Salford); Dr. H. O. J. Collier (director of pharmacological research, Parke Davis and Co., Ltd.); Dr. J. W. Cook (vice-chancellor, University of Exeter); Prof. P. V. Danckwerts (professor of chemical engineering science, Imperial College of Science and Technology, London, and Shell professor-elect of chemical engineering, Cambridge); Prof. E. Giffen (professor of civil and mechanical engineering, Queen Mary College, London); Dr. A. A. Griffith (research consultant, Rolls-Royce, Ltd.); Sir Stanley Harley (managing director, Coventry Gauge and Tool Co., Ltd.); Prof. A. J. Murphy (principal, Cranfield College of Aeronautics); Mr. P. E. Sleight (head of the Civil Engineering and Building Department, Brighton Technical College); Dr. G. B. B. M. Sutherland (director, National Physical Laboratory); Dr. J. S. Tait (principal, Northampton College of Advanced Technology, London); Dr. J. Topping (principal, Brunel College of Technology); Dr. R. C. G. Williams (chief engineer, Philips Electrical, Ltd.).

In addition to the members listed, the Court intends to appoint to the Board one more member of the teaching staff of a College of Advanced Technology. A further statement will be issued as soon as possible giving the details which will be needed for the submission of applications for registration as candidates for membership of the College of Technologists.

Jobs for School Leavers

INTERESTING proposals for dealing with the 'bulge' have been put forward by John Wellens, an industrial training consultant. This year some 900,000 boys and girls will reach the age of fifteen and in 1962 the figure will rise to 1,000,000. As at present organized, industry and commerce are quite unprepared to absorb the considerable extra number of school-leavers who owe their existence to increased birth-rate during and immediately after the War. The training facilities available for those that can be absorbed are inadequate by the most elementary of standards. To deal with the situation, Wellens suggests that a national industrial training agency should be formed, responsible to the Minister of Labour and National Service, and that the existing Industrial Training Council should act as an advisory body to the Agency ("The Bulge: Its Industrial Impact. A National Plan". John Wellens Organization, 24 Morsley Road, Grasscroft, nr. Oldham. 5*s*.). Details of the way in which the agency would work are elaborated as well as the main lines it should follow. It is doubtful whether the somewhat impractical proposals will command any wide support.

Government Support for Research in Water Supply

THE Department of Scientific and Industrial Research is to give financial support to the Water Research Association. The council of the Association has been strengthened by the appointment of Mr. J. E. Beddoe, assistant secretary, Water Division, Ministry of Housing and Local Government, of Dr. B. A. Southgate, director, Water Pollution Research Laboratory, and of Mr. G. A. McMillan, Department of Scientific and Industrial Research. The Department of Scientific and Industrial Research has appointed Prof. F. H. Garner (Birmingham) and Mr. C. S. Tanner (Imperial Chemical Industries, Ltd.) as 'visitors'.

The Water Research Association commenced with an income of £11,000. This rose to more than £20,000, but the research needs of the water industry are, with the increasing demands for water, so pressing that the water undertakings have decided to double their subscription to the Research Association and the Department of Scientific and Industrial Research has offered grant-in-aid up to £27,000. With an anticipated income of £72,000 the Association is moving its laboratories from Surrey to a site on the Thames in Buckinghamshire, where with an increased staff it can augment its present programme of work on the coagulation process of water purification, leak detection and plastic pipes, by the addition of filtration studies, dewatering of sludge, biological and chemical analytical methods and algal growth control. It will also pursue some of the hydrological interests of the water industry.

Science Information News

The National Science Foundation is issuing a new bi-monthly bulletin, *Science Information News* (1, No. 1; February–March 1959. Published bimonthly. Annual subscription, 1.75 dollars. Single copies, 25 cents. Washington, D.C.: National Science Foundation, 1959. Obtainable from the Superintendent of Documents, U.S. Government Printing Office), to provide a medium for reporting new and improved methods of disseminating scientific information and news of activities in this field. The first issue (February–March 1959) deals with the establishment by the National Science Foundation of its Science Information Service, the appointment of the Science Information Council and the establishment of the Federal Advisory Committee on Scientific Information and of a Research Advisory Service on Information Processing. There are, however, notes on the International Conference on Information Processing to be held in Paris during June 13–23, on the expanded programme planned by the Office of Critical Tables of the National Academy of Sciences–National Research Council, the study by the Columbia University Bureau of Applied Social Research of the flow of scientific information among scientists, and the study by the Case Institute of Technology of scientific communication among chemists. It is hoped that in future issues the bulk of the bulletin will comprise material contributed by readers and outside the Foundation's own activities in this field.

Royal College of Science and Technology of Glasgow

The latest annual report of the Royal College of Science and Technology, Glasgow, records no major building developments in 1957–58, but of a number of alterations the largest was the conversion of St. Paul's Church for the use of the School of Navigation. This building has yielded accommodation of a high standard and the rooms previously occupied by the school have been taken over by the Department of Natural Philosophy. Full-time students increased from 1,508 in 1956–57 to 1,662, part-time day students from 1,119 to 1,349, while evening students decreased from 2,346 to 2,109. Besides a list of titles of theses presented by 21 members awarded higher degrees by the University of Glasgow, and of those approved for the awards of the postgraduate diploma of the College, the report includes a list of recent publications by members of the College. Further information on research work in progress is given in the Research Report for the Session 1957–58, in which abstracts of most of the publications listed are appended to the summaries of the work in progress in the various Departments.

Jubilee of Queen's University, Belfast

It is just fifty years since, under the Irish Universities Act of 1908, The Queen's College, Belfast, founded in 1845 as part of a government plan for the extension of university education in Ireland, was dissolved and The Queen's University of Belfast was established. The retention of the title 'Queen's' for the new university was intended to show continuity with the foundation of 1845 and to proclaim adherence to the principle of non-sectarian education on which the old Queen's College (and those at Cork and Galway) had been established. This continuity is reflected in the short history of the College and the University, written by Prof. J. C. Beckett, which has been issued as a booklet (Queen's: a Short History of Queen's College, Belfast, and the Queen's University of Belfast. Pp. 10. 6*d*. Belfast: Queen's University, 1959), although the developments of the past fifty years occupy about half the account.

A new building, called the David Keir Building, to accommodate the Departments of Engineering, Chemistry, Zoology and Botany, was opened by the Duke of Edinburgh on May 21. The plans for this extension were described in *Nature* of February 19, 1955, p. 323.

Museum Treatment of Weakened Fabrics

In the issue of the *Museums Journal* of January 1959, Mr. E. R. Beecher describes a method of conserving fragile woven fabric by heat-sealing to prepared nylon net, allowing the intimate overall support provided by adhesion, while preserving the intrinsic textile quality of flexibility, of which some vestige may survive even in the worst example. The nylon net used is described technically as 15 denier 100 per cent bobbin with a count of 42/43 per sq. in. It is sold as 'Nylusion tulle'. Textile fabric thus mounted—full details are to be found in the article quoted—can be examined on both sides. The method is also reversible as a touch of acetone will dissolve the film on the nylon and allow it to be lifted away.

Resin-bonded Coatings of Polytetrafluoroethylene

Thin films of polytetrafluoroethylene on metal and other surfaces are in use because of their properties of low friction, stability at high temperatures, resistance to chemical attack and weak adhesion. Methods of fixing the film on to the base material involve sintering at 400° C., and for this reason films on rubber, plastics, wood and certain metals have not easily been obtained. A dispersion of polytetrafluoroethylene, under the trade name 'Emralon' (Acheson Colloid, Ltd.), has now become available and enables a coating of the polymer to be resin-bonded at low temperatures to a variety of surfaces. The advantage of this coating over the pure polytetrafluoroethylene film is its applicability to heat-sensitive surfaces, although, in addition, stronger adhesion and greater resistance to wear and corrosion are claimed. Of the two grades available, one uses a phenolic resin binder which can be applied by air spray and requires curing for one hour at 150° C.; the second contains a thermoplastic resin binder and needs no heat curing, so that it can be applied to surfaces where baking, even at 150° C., is impracticable.

Geological Society of London: Officers

At the recent annual general meeting of the Geological Society of London the following officers were elected: *President*, Dr. C. J. Stubblefield; *Secretaries*, Mr. J. M. Edmonds and Dr. P. A. Sabine; *Foreign Secretary*, Prof. O. T. Jones; *Treasurer*, Mr. P. Evans; *Vice-Presidents*, Mr. A. J. Butler, Prof. L. Hawkes, Mr. T. C. Nicholas, and Dr. E. I. White.

Institution of Metallurgists: Officers

The following were recently elected to office in the Institution of Metallurgists: *President*, Prof. A. J. Murphy (College of Aeronautics, Cranfield); *President-elect*, W. E. Bardgett (United Steel Companies, Ltd.); *Vice-Presidents*, Dr. W. O. Alexander (Imperial Chemical Industries, Ltd., Metals Division), Prof. J. W. Cuthbertson (University of Nottingham); *Hon. Treasurer*, Dr. E. G. West (Aluminium Development Association).

Royal Society of South Africa: Officers

The following were recently elected to office for 1959 in the Royal Society of South Africa: *President*, A. J. H. Goodwin; *Hon. General Secretary*, W. J. Talbot; *Hon. Treasurer*, Dr. N. Sapeika; *Acting Hon. Editor of Transactions*, Dr. S. Amdurer; *Hon. Librarian*, Dr. J. H. Day. *Other Members of Council*, Dr. S. H. Haughton, Dr. F. G. Holliman, Dr. W. E. Isaac, Dr. R. F. Lawrence, Dr. R. H. Marloth, Dr. S. M. Naudé, Dr. S. H. Skaife, Dr. R. H. Stoy, and Dr. C. L. Wicht.

The Night Sky in June

New moon occurs on June 6d. 11h. 53m. U.T. and full moon on June 20d. 20h. 00m. The following conjunctions with the Moon take place: June 10d. 15h., Venus 7° N.; June 10d. 18h., Mars 6° N.; June 18d. 11h., Jupiter 3° S.; June 21d. 05h., Saturn 4° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Mars on June 14d. 13h., Venus being 0·8° N., and Mercury with Pollux on June 24d. 09m., Mercury being 5·0° S. Mercury will be visible for a short time after sunset during the second half of the month. Venus is an evening star, visible in the south-west after sunset. Conditions are favourable for observation. Venus sets at 23h. 25m., 23h. 05m. and 22h. 30m. on June 1, 15 and 30, respectively; its stellar magnitude is − 3·9. Its distance decreases during the month from 82 to 60 million miles and the visible portion of the apparent disk decreases from 0·607 to 0·455. Mars is in Cancer during the month. It sets at 23h. 30m., 23h. 00m. and 22h. 15m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is about + 1·9; it is rapidly approaching conjunction, and is low in the west after sunset. Jupiter sets at 3h. 20m., 2h. 20m. and 1h. 10m. on June 1, 15 and 30, respectively. It is in retrograde motion in Libra. The stellar magnitude of Jupiter is − 2·0; its distance is approximately 420 million miles. Saturn is in Sagittarius, rising at 21h. 55m., 20h. 55m. and 19h. 40m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is + 0·3 and its distance is approximately 850 million miles. There is one occultation of a star brighter than magnitude 6 visible at Greenwich: June 11d. 21h. 21·2m., 162 B. Vir. (*D*). *D* refers to disappearance. The summer solstice occurs on June 22d. 04h.

Announcements

Dr. Louis Essen, a senior principal scientific officer at the National Physical Laboratory, has been awarded the A. S. Popov's Gold Medal by the Academy of Sciences of the U.S.S.R. This award is for the most distinguished scientific work in the field of radio-engineering performed during the period 1956–58. Dr. Essen has also recently received the first Wolfe Award of the Department of Scientific and Industrial Research (see *Nature*, 183, 930; 1959). The work of scientists from all countries is considered, but this is the first time that it has been awarded to a scientist outside the Soviet Union.

Prof. W. M. Elsasser, professor of theoretical physics at the Scripps Institution of Oceanography and the University of California, La Jolla, California, has been awarded the William Bowie Medal. The Medal is awarded for outstanding contributions to the geophysical sciences.

Dr. Robert T. Parker has been appointed head of the Banbury and Geneva offices of the Aluminium Laboratories, Ltd., in succession to Mr. R. D. Hamer.

Dr. Herman H. Goldstine has been appointed resident manager of the Lamb Estate Research Center of the International Business Machines Corporation, Cortlandt, New York. As resident manager, he will be responsible for IBM research on business theory, psychology, programming, information theory, mathematics, pattern recognition and operational research. Dr. H. J. Greenberg has been appointed manager of the Mathematics Theory Department of the Lamb Estate Research Center.

The Fulmer Research Institute, at Stoke Poges, Bucks., will hold an open day on July 16. Attendance will be by invitation only.

The autumn meeting of the Radiofrequency Spectroscopy Group, which will be held at the Clarendon Laboratory, Oxford, during September 17–18, is to be devoted to the radio-frequency spectroscopy of free atoms and molecules, with sessions on atomic beam and optical methods, microwave gaseous spectroscopy and the measurement of fundamental constants by radio-frequency methods. Registration forms (with requests for accommodation, which must be returned before July 1) can be obtained from Prof. B. Bleaney, Clarendon Laboratory, Oxford.

An International Oceanographic Congress, sponsored by the American Association for the Advancement of Science in co-operation with Unesco and the International Council of Scientific Unions, will be held in the United Nations building, New York, during August 30–September 12. Further information can be obtained from Dr. Mary Sears, Woods Hole Oceanographic Institution, Mass.

The Ninth International Botanical Congress will be held in Montreal, during August 19–29, at the University of Montreal, McGill University and Sir George Williams College, under the auspices of the Canadian Department of Agriculture. Dr. W. P. Thompson, president of the University of Saskatchewan, has been elected president of the Congress. The programme will be conducted in sixteen sections and will deal with all aspects of botany in its broadest sense, including plant production, breeding, and protection and their implications for agriculture and forestry. Inquiries should be directed to the secretary general, Dr. C. Frankton, Ninth International Botanical Congress, Science Service Building, Ottawa, Ontario.

ANTARCTIC METEOROLOGY

A SYMPOSIUM on "Antarctic Meteorology" was held in Melbourne during February 18–25. It was attended by meteorologists from eleven countries. About half the participants had been in the Antarctic during the preceding year, and this gave the discussion an added interest and a feeling of immediacy. The preparatory work carried out at the Commonwealth Bureau of Meteorology, and the smooth organization under the chairmanship of W. J. Gibbs, as well as the friendly hospitality, contributed to the success of the meeting.

The following topics were discussed in seven successive sessions, each with its own session chairman: (1) local effects (K. Langlo); (2) synoptic analysis and forecasting (J. Van Mieghem); (3) synoptic influences on lower latitudes (J. F. Gabites); (4) circulation studies (W. J. Gibbs); (5) snow and ice characteristics (G. de Q. Robin); (6) heat and mass exchanges (C. H. B. Priestly); (7) climatological aspects (J. J. Taljaard).

In practice, certain themes went through the whole symposium and were discussed repeatedly in different sessions from different points of view. One of these was the katabatic wind, which is one of the most spectacular features of antarctic meteorology. Descriptions of local katabatic winds at Mawson, Wilkes, and over the ice cap were given by P. J. R. Shaw, J. Zimmerman and K. B. Mather. The abrupt onset of katabatic winds at D'Urville and other coastal places may be accompanied by an advancing wall of drifting snow; this so-called Loewe's phenomenon was described by B. Valtat. B. L. Dzerdzeevski discussed the effect of the local topography and of the general synoptic situation upon the genesis of the katabatic winds and G. M. Tauber showed that their intensity depends on cyclonic activity over the oceans near the coast. Tauber also discussed the annual and diurnal variation of these winds in coastal regions and suggested that the diurnal variations must cause the turbulent vertical transport of heat to have a maximum during night time. R. H. Clarke described model studies carried out with the aid of a cold dome in a rotating dish pan. One of the most interesting papers on katabatic winds was presented by F. K. Ball. It gave the theory of airflow under an inversion along a rough, inclined surface. The theory indicates that katabatic stream lines should form an angle of about 40° with the fall line. Along the coast, this causes relatively strong winds at the eastern side of a headland or on the western shores of a bay. It also causes particularly strong katabatic winds in the south-west quadrant of off-shore depressions. These theoretical predictions are in good agreement with observations and with Tauber's investigations.

Another subject which came up repeatedly in different sessions was the intense heating which occurs in the antarctic stratosphere in spring. The antarctic stratosphere at 20 km. cools gradually by about 60° C. from February to September. With the return of the Sun the stratosphere warms up again; a large part of the warming (65 per cent) is accomplished within a few weeks towards the end of October or early November. K. Hanson presented a case-study of this explosive stratospheric warming over the Antarctic in October 1958. Conditions in 1957 were described by E. Flowers. Comparing arctic and antarctic conditions, H. Wexler (whose paper was presented in his absence by M. J. Rubin) directed attention to the fact that the heating in the Arctic is slightly less pronounced and that it occurs before the return of the Sun in February. In the Antarctic it occurs well after the return of the Sun. Wexler explained the spectacular warming of the polar stratosphere by a change in the circulation patterns which leads to large-scale subsidence. This view is not easily reconciled with investigations into advection across the antarctic boundary by M. J. Rubin, whose studies showed no evidence of systematic divergence from the Antarctic in the troposphere and lower stratosphere during summer. Rubin, however, did not study specifically the period in which the stratospheric heating occurs. E. B. Kraus showed that the heating cannot be due to direct absorption of solar radiation. He suggested that it may be caused by advection of moist warm air in the troposphere which results in a change in the long wave-lengths radiation balance above. This view would be in agreement with Hanson's case-study, which indicates a warming of the lower polar troposphere a few days before the rapid stratosphere heating occurred.

As regards equipment, much interest centred on automatic weather recording systems. American automatically reporting weather stations which did not require manual erection and could be dropped from the air were described by W. S. Lanterman. An automatic non-recording climatological station which had been left by the Japanese expedition at Syowa Bay during winter 1958 was discussed by Y. Morita and N. Murakoshi. Traps to measure the lateral transport of snow by drifting were tested by M. Mellor at Mawson. From an analysis of these drift measurements it was deduced by Mellor and U. Radok that the lateral transport of snow was even larger than had been anticipated hitherto. To gain maximum height for upper air measurements a special balloon valve had been developed at the University of Melbourne. V. D. Hopper stated that balloons equipped with this valve reached generally a height of 35 km. with a maximum of 43·5 km. The result of ozone observations at Halley Bay were described by J. MacDowall.

J. F. Gabites gave a lucid account of the antarctic heat balance. He found the flow of heat across 55° S. to be of the same order or only a little higher than the flow across 55° N. in spite of the greater meridional temperature difference. This could be explained by the smaller effect of friction over the ocean-covered southern hemisphere, which allows the establishment of greater vertical wind gradients and therefore greater horizontal temperature and density gradients.

Circulation in the upper air was the subject of a paper by W. B. Moreland and was also discussed in several other contributions. A stratospheric jet is a well-marked feature of the winter circulation. As in the Arctic, this polar night jet appears to be synoptically separated from the systems of the troposphere. There are, however, significant differences between the two polar regions. In the Arctic the jet core is commonly found at the 25-mb. level; in the south it occurs at a lower elevation. The jet stream persists there also later into the polar day, as may be expected from the later heating of the antarctic stratosphere. It has not been possible so far to investigate synoptically the effect of the final collapse in spring of the polar night jet upon the circulation pattern in lower latitudes.

The scarcity of observations from the Southern Ocean area inevitably affected general circulation studies and the discussion of the interaction between the Antarctic and lower latitudes. In presenting his paper on antarctic synoptic analyses, W. J. Gibbs suggested that the presence and the main features of cyclones and anticyclones can be diagnosed by the analyst though there was still considerable doubt about the reality of frontal analyses. Synoptic studies of cold outbreaks and surges had been prepared by a number of Australian authors (A. K. Hannay, R. Falconer and H. M. Treloar, F. A. Berson and U. Radok). Circulation studies based on synoptic material were presented by J. Langford, I. S. Kerr, H. van Loon and S. Karelski.

Synoptic conditions over the antarctic ice cap itself are now reasonably well known for the first time. The communication system required to achieve this end was described by T. I. Gray, jun. It appears that cyclones do occasionally penetrate deep into the Antarctic and that fronts move sometimes right across the South Pole, though this occurs not as often as is probably the case in the north. In general, high-latitude cyclones seem to move sluggishly along the coast.

The happy international co-operation established between meteorologists in the Antarctic is perhaps symbolized by a paper submitted by P. D. Astapenko (U.S.S.R.) which was based on a joint investigation by him, J. Alt (France) and M. Ropar (United States). It is hoped that this co-operation will be continued in the International Antarctic Analysis Centre which is now being set up under the ægis of the Australian Bureau of Meteorology at Melbourne and that the work carried out there will lead to a better understanding of meteorological problems as a whole.

E. B. Kraus

HYDROGEN LIQUEFACTION

The use of liquid hydrogen, first produced and collected by Dewar at the Royal Institution in 1898, has, until recently, been largely confined to the laboratory. With a normal boiling point of 20·4° K. it provides a convenient means of controlling the temperature for experiments in the range 14°–90° K. and it is used as a precooling agent in the liquefaction of helium.

On March 12, a one-day symposium on "Hydrogen Liquefaction and Associated Techniques", organized by the Low Temperature Group of the Physical Society, was held at the Institute of Physics in London, and it was evident from the attendance at the meeting, as well as the topics discussed, that interest in the liquefaction of hydrogen on an industrial scale is developing in Great Britain.

The morning session, under the chairmanship of Dr. P. H. Sykes, was opened by Prof. G. O. Jones (Queen Mary College, London), who spoke of the applications of liquid hydrogen in pure research. He pointed out that it is necessary to go well below temperatures obtainable with liquid hydrogen in order to study the interesting features of many phenomena. Nevertheless, liquid hydrogen is of great technical assistance in many experiments. In optical spectroscopy, for example, the reduction in thermal motion of atoms at low temperatures results in a decreased Doppler broadening of spectral lines. The use of liquid hydrogen in bubble chambers, where it may form both a target and a detector for nuclear reactions, has also proved of great value.

In certain experiments, however, there is little point in working at temperatures below 20° K. For example, the thermal expansion coefficients of most substances and variations in such properties of the solidified inert gases as the density, compressibility and refractive index become so small below 20° K. that they are difficult to measure with precision. Such experiments may very conveniently be performed in miniature hydrogen liquefiers with about 100 ml. of liquid and in which liquefaction commences some 15 min. after starting at room temperature.

The design and construction of small-scale liquefiers were discussed by Dr. D. H. Parkinson (Radar Research Establishment, Malvern), who emphasized the ease with which liquid hydrogen may be produced in the laboratory with relatively simple and inexpensive apparatus. High-pressure hydrogen, usually from a cylinder, is precooled with liquid nitrogen and then expanded at a valve into a reservoir. A proportion of the gas liquefies and the remainder is used to cool the incoming high-pressure gas by means of a heat exchanger between the liquid hydrogen and nitrogen stages. The yield of liquid depends rather critically on the pressure and precooling temperature; for example, a standard 120 cu. ft. capacity cylinder exhausted from 120 to 50 atmospheres would yield 0·36 litre of liquid if the gas were precooled to 77° K. and 0·55 litre with a precooling temperature of 65° K. Impurities, usually amounting to about 0·1 per cent in commercial hydrogen, must be removed from the gas or they will solidify and block the liquefier tubes, and 150 gm. of activated charcoal cooled in liquid nitrogen was recommended as an adequate absorber for each cylinder of gas.

The use of liquid hydrogen as a source of 'cold' has already been mentioned, and an application to the production of a beam of low-energy neutrons was described by Dr. F. J. Webb (Atomic Energy Research Establishment, Harwell). Neutrons from a reactor with, say, a heavy-water moderator at a temperature of 50° C. are thermal neutrons, that is, slow neutrons with energies of the same order as the thermal energies of atoms in a solid. They are spread over a range of values with the greatest number possessing energies corresponding to a de Broglie wave-length of about 1 A. In certain diffraction experiments, however, it is necessary to employ neutrons with wave-lengths greater than 4 A., the number of which is relatively small compared with those of 1 A. wave-length. Since the thermal energy is proportional to the absolute temperature, the kinetic energies of the neutrons may be reduced, and their wave-lengths correspondingly increased, by using liquid hydrogen as a moderator. In the *Dido* reactor at Harwell, a small hydrogen liquefier feeds a 3-in. diameter container placed in the neutron beam and the liquid hydrogen moderator results in a gain of the order of

25 in the flux of neutrons of the required wavelength.

Another application of liquid hydrogen to pure research was described by Mr. C. van Zyl (University College, London), who spoke of its use as a scattering target for high-energy particles. Interactions between two particles such as the proton and the neutron are being investigated as an approach to an understanding of the many-body problem. By employing three targets, one of liquid hydrogen, one of liquid deuterium, and a blank target to eliminate background scattering, it is possible to study *n–p*, *p–n*, *n–n* and *p–p* reactions in the same apparatus.

One of the difficulties encountered in building apparatus for low-temperature work is that of providing vacuum-tight windows for particles or radiation without causing appreciable absorption or scattering. Mr. van Zyl described windows for the target chambers made of thin (0·002 in.) 'Terylene' film which will contain liquid hydrogen when the chambers are surrounded by a high vacuum.

As every schoolboy knows, the considerable size of a space rocket is largely accounted for by the quantity of fuel required to deliver a given load, and the search for more exotic fuels proceeds apace. The ultimate performance of a ballistic vehicle depends upon its 'burn-out' velocity, and this is inversely proportional to the square root of the molecular weight of the fuel. Thus, the best rocket fuels have low molecular weights and are generally rich in hydrogen. From this aspect, liquid hydrogen is obviously a desirable choice, and in the afternoon session, under the chairmanship of Dr. M. Ruhemann, the possibilities were discussed by Mr. A. V. Cleaver (Rolls Royce, Ltd.).

It is estimated that combustion of hydrogen–oxygen mixtures would increase the thrust by some 40 or 50 per cent over that obtainable with conventional kerosene and liquid oxygen fuels. Against this must be set the complications of accommodating a liquid of low boiling point and low density which would tend to reduce the quantity of propellant carried by the rocket. However, recent improvements in the construction of fuel tanks, so that they contribute to the structural rigidity of the rocket and reduce its unladen weight, would seem to make the use of liquid hydrogen more feasible. Although no work is being conducted in Britain, encouraging results have been achieved in the United States with small rocket motors using liquid hydrogen and liquid oxygen.

Clearly, if liquid hydrogen were successfully employed as a fuel, the demand would exceed present production capacity very considerably. With this possibility in mind, Mr. W. L. Seddon (Petrocarbon Developments, Ltd.) presented a design study of a plant capable of producing 2 tons (about 30,000 litres) of liquid hydrogen per hour. This may be compared with one of the few large plants in existence, that at Boulder, Colorado, with a potential capacity of 600 litres per hour.

Hydrogen gas would be derived from oil refinery light hydrocarbon products, and since it is difficult to predict the future demand for liquid hydrogen the economics of the scheme were based on the production of heavy water by distillation. Liquefaction would take place by Joule–Thomson expansion of compressed hydrogen, but one difficulty would be the removal of impurity, ½ per cent of nitrogen present in the feed gas resulting in the deposition of 300 lb. of solid per hour. It was therefore proposed to precool the feed gas to about 35° K. with the aid of expansion turbines and expand the gas from a pressure of about 16 atmospheres. Under these conditions, the efficiency of the Joule–Thomson process remains fairly high and a considerable proportion of impurity is carried through the expansion valve and deposited in the liquid reservoir, where it may easily be removed.

The capital cost of such a plant is in the region of £6,000,000, and the estimated price of the product, allowing for the sale of heavy water as a by-product, is £200 per ton. Liquid hydrogen produced on this scale would therefore work out at a cost of about 1*s*. a gallon, comparing surprisingly favourably with hydrocarbon fuels at, say, 4*s*. 8*d*. a gallon.

On a somewhat smaller scale, a paper by Dr. B. Shaw and Mr. W. H. Denton dealt with the problem of coping with a varying demand at the Atomic Energy Research Establishment, Harwell, by storing liquid hydrogen in 50-litre Dewar vessels. Hydrogen consists of molecules in two different rotational states, the equilibrium concentration being 75 per cent *ortho*-hydrogen and 25 per cent *para*-hydrogen, but the liquid is slowly converted to the *para* form with evolution of heat. In storage, therefore, liquid is lost by *ortho–para* conversion and it is usually more desirable to induce the conversion before liquefaction by passing the high-pressure gas over a catalyst such as ferric oxide or activated charcoal at low temperatures. Dr. Shaw presented figures showing that, for short-term storage, greater overall economy is gained by carrying out partial conversion at 80° K. than by converting completely to the para form at 20° K. The total loss from a 50-litre Dewar vessel with liquid nitrogen shielding may be as low as 0·18 litre per day.

For storage on a large scale, however, a vacuum-insulated vessel employing a liquid nitrogen radiation shield would be unduly large and complicated and the feasibility of using thermal insulation similar to that now employed in liquid nitrogen and oxygen storage vessels was discussed in a paper by Mr. K. C. Smith and Dr. J. B. Gardner (British Oxygen Research and Development). In these vessels, the liquid is surrounded by a space evacuated to a pressure of 10^{-1} mm. mercury and packed with an insulating powder. For liquid hydrogen, the loss from such a vessel would chiefly be due to radiation, and Mr. Smith described measurements of the overall thermal conductivity resulting from the addition of reflecting particles, such as aluminium powder, to the powders commonly in use. They show a significant decrease in thermal conductivity and indicate that the thickness of insulation need not be inconveniently great in, for example, a vessel of 10 ft. in diameter. Similar considerations are being applied to the design of transfer lines for large quantities of liquid.

The question of safety must be given prime consideration when dealing with liquid hydrogen, and some general remarks were made by Dr. A. J. Croft (Clarendon Laboratory, Oxford), who stressed the importance of making provision for possible human errors in operating liquefiers. Many of the precautions are common to any equipment containing low boiling-point liquids or gases at high pressure, as, for example, the fitting of relief valves to prevent the pressure rising above a safe value. One must also adopt the precautions normal when dealing with a highly inflammable liquid or explosive vapour, such as adequate ventilation of buildings. The consequences of a mishap should be minimized by partly enclosing liquefying plant by blast walls and by operating it remotely. This, of course, is not always feasible, particularly with small-scale laboratory installations.

Happily, there have been few serious accidents attributable to the use of liquid hydrogen, and reasonable and sensible safety precautions would appear to suffice. Judging by the papers and discussions presented at this symposium, it is conceivable that, in the future, liquid hydrogen will be produced and handled on a scale and with a facility comparable to that encountered to-day with liquid oxygen.

D. H. BOWEN

PARASITOLOGY

THE first meeting outside London of the Parasitology Group of the Institute of Biology was held in the Zoology Department, University of Edinburgh, during March 19–21. It was the longest session so far held and the range of topics discussed was limited only by the general heading of "Parasitology".

Twenty-five papers were read, covering subjects as varied as the use of antigen–antibody reactions to differentiate species and strains of *Entamoeba* (V. Zaman), and the morphology, function and taxonomic status of the adhesive apparatus of Amphibdellatid parasites of electric rays (J. Llewellyn).

Some of the speakers were concerned with the mechanisms which trigger the changes in parasite life-histories. E. W. McConnachie reviewed the possibility that the onset of sexual reproduction of some parasites is related to hormonal changes in the host, and outlined her preliminary experiments with *Opalina* in frogs which tentatively support this view. Assuming a direct effect of the host's hormones on the parasite, one would have to postulate the presence of such hormones at the site of parasitism, which, for *Opalina*, is the lumen of the frog's rectum. Coccidian Protozoa would seem to be in a more favourable position to be influenced by systemic changes in the host since they develop in the epithelial tissues of the gut, but S. F. M. Davies showed that no mechanism of this kind was needed by *Eimeria necatrix* in chicks, the sexual phase of development being initiated by second-generation merozoites irrespective of the physiological state of the host.

The evolution of a temperature trigger mechanism in the life-cycle of certain tapeworms was argued by C. A. Hopkins on the basis of ecological studies on *Proteocephalus filicollis* in sticklebacks. He showed that in the north of Britain very few of the immature stages of these worms complete their development, even though they become successfully established in the fish host. Comparison with the state of affairs in the south suggested that low temperature can arrest development of such a species, limited, as it is, to cold-blooded hosts. An elegant solution to the parasite's problem would be the inclusion in the life-cycle of an 'incubator' in the form of a warm-blooded host. Hopkins suggested that this may have happened in the case of three-host pseudophyllidean tapeworms, since a rise in temperature is almost sufficient on its own to mature the plerocercoids of some of these parasites.

Mechanisms which enable free-living stages to locate their hosts were considered in two papers, one by C. A. Wright, the other by C. Ellenby and A. B. Gilbert. The former put forward evidence in favour of a response by trematode miracidia to substances exuded by their molluscan hosts. Ellenby and Gilbert presented a progress report on work with the hatching factor of potato root eelworm and showed that their results were still consistent with the view that an unsaturated lactone ring is diagnostic of the molecule of the active constituent of potato root diffusate.

Problems more comprehensive than trigger mechanisms were considered by E. J. Bell, C. A. Hopkins and M. R. Wyllie. These workers described their joint efforts to bridge the gap between the analytical and synthetic aspects of the *in vitro* culture of strigeid metacercariae to the sexually mature adult fluke. Media synthesized from chemically defined and simple constituents were very limited in their ability to promote growth and had to be assessed by sensitive criteria, such as cell-division, rather than by an increase in size of the organism or its parts. On the other hand, some of the unknowns of complex media which do support considerable growth could now be replaced by known substances, but the gap between the two approaches was still formidable.

Experiments which illustrate the differences that may exist between the metabolism of host and parasite were described by L. P. Joyner. Both sulphadimidine and pyrimethamine on their own showed therapeutic effect when administered to chicks infected with *Eimeria tenella*, but the two administered together gave more than additive effect. This is consistent with the theory that they antagonize different links in the same metabolic chain of the parasite, namely, the *p*-aminobenzoic acid – folic – folinic acid sequence. The drugs are also toxic to the chick, but when they were administered, together with the metabolites they are presumed to antagonize, differential reversal of their effects on host and parasite occurred.

Investigations into mechanisms concerning resistance of hosts to their parasites were reported by a number of speakers. F. W. Jennings presented the findings of a team of workers on immunity to *Dictyocaulus* infection in cattle. He showed that a double 'vaccination' of the host with irradiated infective larvæ protected it against further challenges of normal larvæ. L. Bailey dealt with the resistance of honeybees to epidemics of a range of parasites, and described how, without the aid of acquired immunity, the behaviour of the colony as a whole constituted a 'group immunity' reaction, and was successful in combating the disease as long as the community could develop normally. This was in part analogous to the dynamics of *Sarcoptes scabiei* infections in man, considered in two papers by K. Mellanby and W. N. Boog Watson, though in this case acquired immunity was an additional factor. The breakdown of resistance to infection in 'resistant' strains of potato by certain biotypes of potato root eelworm, and the investigation of its genetic basis in the nematode, was discussed by F. G. W. Jones. The evidence suggested a single locus for the effect, the double recessive conferring resistance-breaking, though the fact that some of the heterozygotes were resistance-breakers was against this simple interpretation.

The advantages of such a wide field at a conference of this kind were illustrated by the implications of the use of resistant species or strains to reduce the number of infective stages available to others that are susceptible. This is known to be valuable in the case of potato root eelworm, where resistant strains of the plant nevertheless stimulate hatching of the cysts, and was suggested by H. D. Crofton and P. G. Yonge as a mechanism in the control of *Diphyllobothrium* infections in trout when a normal proportion of coarse fish is present to reduce the level of infective material.

A plea to parasitologists not to lose sight of the economic aspect in the aims they set themselves when investigating the parasitic diseases of domestic animals was put forward by M. Christie. However, in the case of infections in man the parasitologist has a duty to assist in divesting him of his parasites. Contributions with this goal in mind included a mathematical analysis by W. E. Kershaw of the effects of parasitic infections on the mortality of insect vectors. These effects differed with the parasite and the vector, but the ability to support the parasite decreased with increasing age of the insect host, so that the vector may be present and yet incapable of transmitting the disease. Studies reported by A. I. Wright revealed an understandable, but nevertheless alarming, lack of knowledge of the etiology of hydatid disease on the part of some keepers of foxhounds in England, and showed that dogs fed on raw meat and offal readily become infected with *Echinococcus granulosus*.

No meeting of this kind would be complete without the description of a hitherto unknown animal. This was provided by J. Mahon, who presented studies on a new tapeworm, together with her reasons for placing it in the family Dilepididae.

P. A. G. Wilson

HORTICULTURAL AND FRUIT RESEARCH

The agricultural side of the work of the Agricultural and Horticultural Research Station at Long Ashton has been concerned mainly with fruit farming, but the retiring director, Prof. T. Wallace, had earlier described and photographed in colour the symptoms of numerous mineral deficiencies on a wide variety of crops. This raised so many questions that a research unit on plant nutrition was formed and is now firmly established at the Station under the ægis of the Agricultural Research Council. The annual report for 1957*, which was recently published, includes results of current work by this Unit on molybdenum deficiency, which has complex relations with nitrogen sources and with phosphate. A new type of symptom has indeed been produced when ammonium sulphate was used as a nitrogen source in place of nitrate. Other work of the Unit is outlined in the research summary of the report; much of it is obviously of a preparatory nature, but the results should ultimately provide knowledge upon an altogether new plane of detail for studies in plant nutrition.

In the main part of the report, C. Bould reports that two synthetic soil conditioners, HPAN (sodium salt, hydrolysed polyacrylonitrile) and VAMA (calcium salt, vinyl acetate maleic acid co-polymer), do indeed improve soil structure, but bring no increase in yield of strawberries. L. C. Luckwill and A. I. Campbell have obtained successful control of bindweed growing among black currant bushes by spraying 300 gal. per acre of 0·1 per cent potassium salt of 2 : 4 : 5-trichlorophenoxybutyric acid (2 : 4 : 5-TB). Long Ashton has undertaken the propagation of a virus-tested clone of loganberries, and E. W. Hobbis and A. I. Campbell have worked out a technique of leaf-bud propagation for its more rapid accomplishment. Barbara A. Rake reports that gooseberry cuttings taken from fruiting bushes root more easily than those taken from younger plants, and A. I. Campbell finds that crab *C* rootstocks are necessary to provide sufficient stem for cider-apple standards. The stem building stock Bulmer's Norman could also, however, be double worked satisfactorily upon a variety of rootstocks. D. Wilson finds that the prolific new pear variety, Bristol Cross, introduced by the Station in 1933, is almost completely male sterile, and should therefore be grown only with a pollinating variety, for example, Conference.

Plant pathology occupies a large part of the report. L. C. Luckwill has obtained evidence that 'chat fruit' disease of the apple Lord Lambourne is transmissible by graft and of virus origin. Spores of the fungi causing apple and pear scab diseases require a period of wetting before they will germinate, the so-called 'Mills periods'. Most of the work on these periods, which have forecast value, was done with ascospores of *Venturia inaequalis* (apple scab), but D. Wheatley shows that conidia of this fungus gave a higher percentage germination and grew more rapidly than ascospores. Conidia of *V. pirina* grew even faster than conidia of *V. inaequalis*, and these facts would necessitate a revaluation of Mills' forecast periods to meet particular situations, according to whether ascospore or conidial infection was involved. Several losses of stored apples have occurred in recent years; they are caused by the fungi *Gloeosporium perennans* and *G. album*, which infect the fruit while still on the tree. R. O. Sharples finds that the fungi complete their life-cycles as weak parasites on apple shoots, that fruit infection is incidental, and that spore production can be reduced by sprays or wound paints containing phenyl mercury chloride. R. T. Burchill shows that apple mildew, *Podosphaera leucotricha*, infects the buds via the petioles, a bud remaining susceptible to attack for about a month after emergence.

R. J. W. Byrde and Nora N. Waugh report laboratory tests of eleven new potential fungicidal materials. Three of them—*n*-dodecyl-guanidine acetate, 2 : 4-dichloro-6-(*o*-chloroanilino)-*s*-triazine, and *o*-hydroxydiphenyl—were selected for field tests. Bordeaux mixture is usually made by adding concentrated copper sulphate solution to diluted lime suspension, but E. Somers shows that better performance can be expected if the lime is concentrated and the copper sulphate dilute. R. J. W. Byrde, G. M. Clarke and C. W. Harper have again found in 1957 that captan used as a post-blossom spray on apples increased the incidence of mildew. J. T. Martin and J. A. Pickard have studied the retention of mercury salts by apple fruits after seven sprays with 0·003 per cent mercury as phenyl mercuric nitrate. A fruit weighing 200 gm. had about 10 µgm. of mercury: 2 µgm. in the peel, 8 µgm. in the flesh and less than 1 µgm. in the core. T. E. Cobbold describes a compressed air nozzle for small-volume spraying, and has also assessed the field performance of the power-knapsack type of mist sprayer. Little is known about the chemical composition of the cuticle in different plants, but J. T. Martin, R. F. Batt and Margaret F. Roberts show that there are considerable variations in the overall amounts of cuticle and in the proportions of wax and cutin between plants. As the cuticle is the initial receptor of sprays, a knowledge of its constitution should be important in practice.

* University of Bristol. The Annual Report of the Agricultural and Horticultural Research Station (The National Fruit and Cider Institute), Long Ashton, Bristol, 1957, with Index 1953–57. Pp. 182 + 10 plates. (Long Ashton, Bristol: Agricultural and Horticultural Research Station, 1958.) 15*s*.

There are also papers on domestic food preservation, on fruit juices, and on the conversion and utilization of the Station's plantation of cricket bat willows. Research workers and advisory officers will find a most useful list of papers published by members of the Station's staff in 1957, and there is a further index of papers published in the Long Ashton annual reports during 1953–57. JOHN GRAINGER

INSECT RESISTANCE TO INSECTICIDES

THE discovery by Müller of the insecticidal properties of DDT in 1939 was followed by the introduction of a whole range of similarly powerful synthetic insecticides in the years immediately after the Second World War. These included other chlorohydrocarbons like dieldrin, the gamma isomer of benzene hexachloride, and a number of organophosphorus compounds. Their use marked a new era in the control of arthropod pests and the development of what is now an important branch of the chemical industry. The spectacular control of the malarial mosquito, for example, brought the global eradication of the disease within the realm of probability.

The development of insect resistance to some of these insecticides, however, now threatens to undermine much of the progress achieved and the hopes of some large-scale public health programmes in tropical latitudes especially. Resistance may attain such levels as to involve virtual immunity of the insect to an insecticide and the failure of effective control in the field. Yet remarkably little is known about the mechanisms of resistance and in no case has a satisfactory counter-measure been developed except to change to one of the dangerously few alternative insecticides. A major problem has been to engage the interest of suitably equipped and experienced workers and to facilitate the exchange of information and insect material between research workers and the often far-distant field entomologist or sanitarian. A good deal has recently been achieved by a small dedicated group of the World Health Organization in Geneva due in no small part to the tireless efforts of Prof. A. W. A. Brown. His recent monograph on "Insecticide Resistance in Arthropods"* is one result of a two-year term-of-office with the Organization and reflects an authority and erudition made possible only by a combination of the uniqueness of the author's position and his personal industry.

Four long chapters deal with the genetic nature and development of resistance, resistance in species which are vectors to man, what is known of the physiological and biochemical mechanisms of resistance, and resistance in species which are not vectors.

The first chapter describes the historical development of resistance in vector species, the public health implications, the genetic nature of the inheritance of resistance, and the important problem of detecting significant levels of resistance in field populations. The second chapter deals *seriatim* with case histories of the vectors such as body lice, and mosquitoes transmitting malaria and yellow fever. The third chapter deals mainly with the housefly, since much the larger part of systematic research has been conducted with this insect. The final chapter, like the second, deals with case histories of the field development of resistance in fruit flies, bed bugs and cockroaches.

The monograph will interest the geneticist as well as entomologist and biochemist. There is abundant evidence that resistance is a pre-adaptive phenomenon and under genetic control, so that the development of resistance to an insecticide is due to selective breeding from naturally resistant phenotypes. The easy culture of highly resistant strains in the laboratory has probably provided an unprecedented opportunity for studying the biochemistry and genetics of evolution.

Prof. Brown has wisely refrained from speculating about the future of the resistance problem and the possible development of countermeasures. These may indeed involve entirely new concepts in the field of insect control. On the other hand, there are grounds for believing that effective counter-measures can be developed on the basis of the continued use of insecticides: for example, the exploitation of enzymes which appear to be present in far higher concentrations in the tissues of a resistant insect than in a susceptible one, or the alternate use of insecticides negatively correlated in their respective toxicities towards susceptible and resistant strains.

Some readers may be disappointed to find relatively little reference to resistance of agricultural pests and its implications. For example, there is no mention of the serious levels of resistance to the chlorinated hydrocarbons, reported in 1957 to have developed in the cotton boll-weevil infesting the larger cotton-growing area of Louisiana. While such an omission is not surprising in a publication of the World Health Organization, it might have been usefully indicated in the title or in a sub-title of the monograph. Prof. Brown has, perhaps, drawn a little heavily on pre-publication material some of which has shown signs of being a little premature. These blemishes notwithstanding, the monograph is a timely and invaluable contribution to an appreciation of this big problem. It is recommended as salutary reading to all interested in the chemical control of arthropod pests and as an essential text to all concerned with the problem of resistance itself.

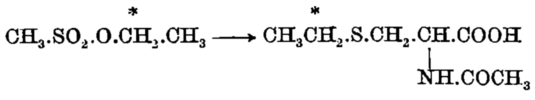
METABOLISM OF MYLERAN (1 : 4-DIMETHANESULPHONYLOXYBUTANE)

By Dr. J. J. ROBERTS and Dr. G. P. WARWICK

Chester Beatty Research Institute, Institute of Cancer Research,
Royal Cancer Hospital, London, S.W.3

EARLIER publications[1,2] on the mode of action of biologically active alkylating agents described the presence of derivatives of S-alkylated cysteines in the urine of rats given alkyl alkanesulphonates by intraperitoneal injection. Thus, for example, 1-^{14}C-ethyl methanesulphonate (I) was shown to be excreted as N-acetyl-S-1-^{14}C-ethylcysteine (II) and other derivatives of S-1-^{14}C-ethylcysteine.



$$\mathrm{CH_3.SO_2.O.\overset{*}{C}H_2.CH_3 \longrightarrow CH_3\overset{*}{C}H_2.S.CH_2.\underset{\displaystyle NH.COCH_3}{\underset{|}{CH}}.COOH}$$

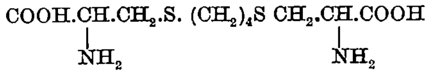
I II

This work was regarded as a prelude and guide to the investigation, now reported, of the *in vivo* reactions of 1 : 4-dimethanesulphonyloxybutane (myleran) (III) ; $n = 4$; a cytotoxic alkylating agent used clinically in the treatment of chronic granulocytic leukæmia[3]. These studies also provide a comparison between the *in vivo* reactions of two structurally related compounds, one monofunctional and the other bifunctional. Myleran is far more toxic to the rat than ethyl methanesulphonate and, unlike the latter, exerts a profound effect on the bone marrow, which results in a drop in the number of circulating neutrophils[4].

$$\mathrm{CH_3.SO_2.O\ (CH_2)_{\mathit{n}}.O.SO_2.CH_3}$$

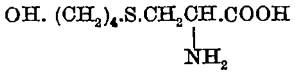
III

By analogy with ethyl methanesulphonate it was anticipated that myleran would react *in vivo* with the thiol group of cysteine or cysteine-containing compounds (peptides or proteins), resulting in the urinary excretion of metabolites of S-dicysteinylbutane (IV). However, evidence for such a reaction product was not obtained, while it was established that injected S-dicysteinylbutane was excreted in the free and conjugated forms. Furthermore, S-(4-hydroxybutyl)cysteine (V), which would be formed if one functional group of myleran reacted with cysteine while the other was hydrolysed, was also shown to be excreted as conjugates of sulphur compounds which were detectable on paper chromatograms. These compounds were not present on similarly prepared chromatograms of urine from rats which had received injections of myleran.



$$\mathrm{COOH.\underset{\displaystyle NH_2}{\underset{|}{CH}}.CH_2.S.\ (CH_2)_4S\ CH_2.\underset{\displaystyle NH_2}{\underset{|}{CH}}.COOH}$$

IV



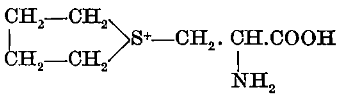
$$\mathrm{OH.\ (CH_2)_4.S.CH_2\underset{\displaystyle NH_2}{\underset{|}{CH}}.COOH}$$

V

After injection of 2 : 3-^{14}C-myleran (prepared by Dr. P. Brookes) into a male Wistar rat, only 4 per cent of the radioactivity was exhaled as carbon-14 dioxide during 24 hr. On the other hand, 2 : 3-^{14}C-1 : 4-butanediol, the hydrolysis product of myleran, was shown to be converted almost exclusively to carbon dioxide labelled with carbon-14 *in vivo*, indicating that myleran is not metabolized via this route. It will be recalled that conversion to carbon dioxide was one of the major routes of metabolism of ethyl methanesulphonate.

Autoradiographs of paper chromatograms of the urine collected during 24 hr. after injection of myleran revealed the presence of one major metabolite, which was stable to treatment with hot mineral acid and failed to give any positive test (on paper chromatograms) with a number of reagents such as ninhydrin or platinic iodide. The necessarily minute doses of myleran which were given to rats precluded isolation of adequate quantities of the metabolite for characterization.

In view of these apparent differences between the metabolism of ethyl methanesulphonate and myleran, the reaction between myleran and cysteine *in vitro* was studied in greater detail. Apart from the formation of some S-dicysteinylbutane and S-(4-hydroxybutyl)cysteine the major product of the reaction under a variety of conditions was the S-β-alanyltetrahydrothiophenium cation (VI).



VI

The ion was characterized as its picrate and was unambiguously synthesized by heating S-(4-hydroxybutyl)cysteine with concentrated hydrochloric acid.

The urine obtained from a rat which had been injected with this sulphonium salt (VI) (prepared from the labelled myleran) also contained one major metabolite identical with that formed from myleran, as judged by comparing autoradiographs of identically prepared paper chromatograms of the respective urines. The identity of this major metabolite has still to be determined ; but since it is no longer an amino-acid it is clearly a break-down product of the cyclic sulphonium ion (VI), possibly a derivative of tetrahydrothiophene. The sulphonium salt (VI) was shown to be labile in the presence of alkali and was converted to alanine by electrolytic reduction.

These results indicate that the predominant reaction which myleran undergoes in the rat is alkylation of a thiol group, and by analogy with ethyl methanesulphonate probably that of cysteine or cysteine-containing compounds, to give a cyclic sulphonium salt, which is the precursor of the major urinary metabolite.

Certain sulphonium ions have been shown to possess alkylating ability, depending both on the nature of substituents and the associated anion. However, the fact that S-dicysteinylbutane or S-(4-hydroxybutyl)cysteine is not produced when (VI) is treated with excess cysteine or water, and that it is not metabolized to these compounds *in vivo*, would suggest that this sulphonium ion is not an alkylating agent. This is supported by the fact that it was found to be non-toxic to the rat, and did not produce myleran-like effects on the bone marrow at a dose as high as 1 gm./kgm. body-weight (L. A. Elson, private communication). It seems likely, therefore, that this compound is not responsible for the pharmacological effects of myleran; but the possibility remains that the ion is unable to penetrate the necessary cell boundaries to produce its effects. Those pharmacological properties of myleran, therefore, which result from reaction with thiol groups are likely to be due to reaction with thiol groups of proteins or nucleoproteins leading to sulphonium ion formation. The formation of such ions may offer an explanation for the differences in pharmacological properties which have been observed between myleran and its monofunctional counterpart, ethyl methanesulphonate. While both compounds have been shown to react with thiol groups *in vivo*, the formation of sulphonium ions from myleran may have more far-reaching effects by modifying the structure and function of macromolecules. It has also been found that in the series of *bis*-methanesulphonyloxy esters[4] (III; $n = 2$–10) maximum toxicity and maximum activity against the neutrophils occur when $n = 4$ or 5, distances which would permit a facile cyclization to five- or six-membered rings, respectively[5]. This view is supported by some preliminary *in vitro* chemical studies of the reaction between cysteine and various members of the series (III; $n = 3$, 5 and 6).

Other alkylating agents such as the sulphur and nitrogen mustards could conceivably undergo *in vivo* ring formation in an analogous manner and work is in progress to determine whether this is the case.

This work has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research, Royal Cancer Hospital) from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. We wish to thank Prof. A. Haddow and Dr. L. A. Elson for their interest in the work, and to record our appreciation for helpful discussion with many of our colleagues. We should also like to acknowledge technical assistance from Miss M. Morton and Miss M. Gill.

WEAL AND FLARE IN HUMAN SKIN PRODUCED BY HISTAMINE AND OTHER SUBSTANCES

By Dr. A. HERXHEIMER and Dr. M. SCHACHTER

Department of Therapeutics, St. Thomas's Hospital Medical School, London, S.E.1,
and the Department of Physiology, University College, London, W.C.1

ALTHOUGH histamine is the most prominent wealing agent in man, evidence is accumulating which indicates that other naturally occurring substances have a similar action on capillary permeability. Among substances that have been found to have this property in laboratory animals are kallikrein[1,2], kallidin, bradykinin, wasp kinin[3] and 5-hydroxytryptamine[4]. The present experiments demonstrate that wasp kinin, kallidin, bradykinin and kallikrein preparations are effective wealing agents in man on intradermal injection. Also, that the size of flare and the size of weal produced by these substances do not run parallel. For example, kallikrein, which increased capillary permeability, produced no flare, whereas 5-hydroxytryptamine, which was an effective flaring agent, failed to cause wealing or other evidence of increased capillary permeability. Until pure substances are available the possibility exists that the permeability-enhancing agents in our preparations are not identical with the smooth muscle contracting (kinin, kallidin, bradykinin) or vasodilator (kallikrein) principles.

Four healthy men, aged 20–23 years, were injected intravenously with 10 ml. of a 5 per cent sterile solution of Evans blue in saline. Intradermal injections (0·05 or 0·1 ml.) of the test substances in saline were made into the skin of the back 30 min. later, and flares and weals were measured 8–15 min. after injection. Measurements were made either directly on the subject or from projected coloured photographs. The mean of the largest diameter and that at right angles to it was taken as the size of the flare or weal; the flare measurement included the diameter of the weal. Serial photographs of the skin reactions indicated that the flare usually reached its maximum in 4 min. and was beginning to fade in 15 min. The weal reached its maximum size in 9 min. and remained so beyond 30 min. Reactions were measured, therefore, 8–15 min. after the intradermal injection. Small weals that were not blue were designated as 0 or 0–4, since they presumably represent injected fluid and not fluid which had left the circulation. These were never, in any event, greater than 4–5 mm. in diameter.

Wasp kinin was prepared by extraction of wasp glands with glacial acetic acid, precipitation with ether, and repeated washing of the precipitate with ethanol. This preparation contained 1 unit in 0·4 μgm. of freeze-dried material. Kallidin and bradykinin were prepared by the action of human salivary kallikrein or trypsin, respectively, on heated ox globulin. These preparations were of equal potency and contained 1 unit in 75 μgm. dry material in terms of the unit of Rocha e Silva, Beraldo and Rosenfeld[5].

Details of the units and preparation of these different substances are given by Holdstock *et al.*[3]. Kallikrein was prepared from the saliva of the subject in whom it was eventually tested. There is as yet no standard of kallikrein in terms of its ability to release kallidin ; the preparation used in these experiments, however, released detectable amounts of kallidin when incubated with heated human plasma in concentrations of 10 µgm./ml. or less.

The results obtained with intradermal injections of 0·05 ml. kinin, histamine and 5-hydroxytryptamine in three subjects are shown in Table 1. Histamine and partially purified wasp kinin produced marked blueing with a large surrounding flare and were approximately equi-active on a weight basis. 5-Hydroxytryptamine produced a flare, but no blueing, even in much higher concentrations. The small, evanescent flare produced by saline was not measurable 5 min. after the injection.

Preparations of bradykinin and kallidin which were of equal activity on the guinea pig ileum were compared with kallikrein, histamine, kinin and 5-hydroxytryptamine in a fourth subject (Table 2). In this experiment, a greater volume, namely, 0·1 ml., of each solution was injected. Kallidin and bradykinin were effective blueing agents but much less active in producing flare. Thus, unlike histamine and wasp kinin (Table 1), they were still producing blueing reactions without an associated flare in high dilutions. Kallikrein, which produced larger weals, was also practically devoid of flaring properties in the concentrations used. 5-Hydroxytryptamine, on the contrary, again elicited a strong flare but no blueing reaction.

Table 1. FLARE AND WEAL PRODUCED BY INTRADERMAL INJECTIONS (0·05 ML.) OF KININ, HISTAMINE AND 5-HYDROXYTRYPTAMINE
(Combined results from three subjects)

Substance	Concentration (µgm./ml.)	Mean diameter (mm.)	
		Flare	Weal (blue area)
Wasp kinin	500	48, 44, 43	15, 14, 10
	50	48, 44, 35	13, 10, 9
	5	32	9
Histamine	500	55, 51	16, 14
	100	47	13
	50	48, 41	10, 10
	10	43	9
	1	30	9
5-Hydroxytryptamine	2,500	35, 32	0–4, 0–4
Isotonic saline		0, 0	0–4, 0–4

Table 2. FLARE AND WEAL PRODUCED BY INTRADERMAL INJECTIONS (0·1 ML.) OF BRADYKININ, KALLIDIN, KALLIKREIN, HISTAMINE AND 5-HYDROXYTRYPTAMINE IN A FOURTH SUBJECT

Substance	Concentration (µgm./ml.)	Mean diameter (mm.)	
		Flare	Weal (blued area)
Bradykinin	1,000	30	15
	333	27	13
	100	0	12
	10	0	10
Kallidin	1,000	28	15
	333	20	9
	100	0	11
	10	0	9
Kallikrein	500	trace	18
	50	0	15
Kinin	100	52	18
Histamine	100	58	20
5-Hydroxytryptamine	100	34	0–4
Isotonic saline		0	0–4

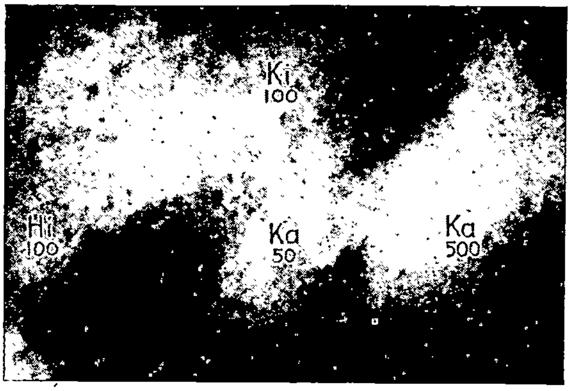

Fig. 1. Photograph of weal and flare reactions of human skin to intradermal injections of 0·1 ml. of histamine (*Hi*), wasp kinin (*Ki*) and salivary kallikrein (*Ka*). The numbers represent the concentration of the solutions in µgm./ml. The subject had received Evans blue solution previously, and the blue weal is the dark central area surrounded by the lighter flare. Note the complete absence of flare with kallikrein

Fig. 1 shows the flare and weal produced by histamine and wasp kinin contrasted with the pure wealing action of kallikrein.

These results indicate that in addition to histamine a number of naturally occurring substances produce wealing in man. They include wasp kinin, salivary kallikrein, kallidin and bradykinin. 5-Hydroxytryptamine, which increases capillary permeability in rat skin[4,6], has no such effect in man, where, however, it is effective in producing the local flare reaction. It is very unlikely, therefore, that the release of 5-hydroxytryptamine is of significance in reactions involving wealing or angio-œdema in man.

The fact that salivary kallikrein and the polypeptide, kallidin, which it releases are effective in increasing capillary permeability is of interest, because plasma contains large amounts of kallikrein in an inactive but activable form[7]. Indeed, there is a suggestive similarity in the blueing of skin produced by salivary kallikrein in our experiments and that produced by diluted human plasma in man[8]. In both instances flare reactions were strikingly absent. It may well be, therefore, that the agent in diluted human plasma which increases permeability is kallikrein, since there is also evidence that dilution of plasma or serum activates kallikreinogen, the precursor of serum kallikrein[9].

In our experiments kallidin itself did produce some flare reaction, although this was much less prominent than with histamine, kinin, or 5-hydroxytryptamine. In higher dilutions kallidin no longer produced any flare although it still caused blueing. Our preparations of kallidin and bradykinin are quite impure, and until pure preparations are available for testing, it will be impossible to say whether the mild flare reaction is produced by the same substance which produces the increase in capillary permeability.

This work was in part financed by a grant from the Central Research Fund of the University of London to one of us (M. S.), which gratefully is acknowledged.

CELLULOSE ACETATE AS A MEDIUM FOR IMMUNO-DIFFUSION

By R. CONSDEN
Rheumatism Research Unit (Medical Research Council), Canadian Red Cross Memorial Hospital, Taplow, Maidenhead, Berks

AND

J. KOHN
Queen Mary's Hospital, Roehampton, London, S.W.15

A NUMBER of well-established methods for demonstrating antibody–antigen reactions depend on the formation of precipitin lines by diffusion through a jelly—usually agar. Some of the difficulties associated with the use of jelly would be avoided if the diffusion process could occur in a sheet of solid material. For satisfactory results such a material would have to be wettable, allow the free diffusion of large molecules without adsorption, have a uniform composition and be readily available. We have found that cellulose acetate membrane (Oxo, Ltd.) fulfils these requirements and is equal, if not superior, to agar jelly for immuno-diffusion purposes. This material, in strip form, was introduced by Kohn[1] for electrophoresis and was later developed, in conjunction with agar, for immuno-electrophoresis[2,3].

For the Ouchterlony–Elek double-diffusion method, pieces of suitable size are cut from a membrane strip or, alternatively, unprinted circular membrane filters may be used. The positions where the samples are to be applied are marked lightly with non-diffusing ink (for example, with a ball-point pen). The membrane is then soaked in the desired buffer solution, blotted lightly so that no excess moisture is visible and supported in a horizontal position in a moist chamber. (A suitable support consists of pins with their heads pressed into a 'Plasticine' base so that the points are uppermost.) By means of capillary tubes, small amounts (1–5 μl.) of the samples are applied as spots or lines to the membrane surface. Antigen and antiserum are usually placed 1 cm. apart, but the arrangement and distance may be chosen as required. The membrane is allowed to remain in the moist chamber until the drops have sunk into the surface, following which it is immersed in a bath of liquid paraffin or 'Whitemor 120' oil (Manchester Oil Refinery Co.). Diffusion occurs in the moist membrane and the formation of precipitin lines is usually complete in 2 days at room temperature. Excess of oil is wiped off, and the remaining oil removed by a quick wash in ether or light petroleum. Thereafter, water-soluble material is removed by soaking in saline or buffered saline solution for 1–3 hr. with occasional agitation. The membrane is then blotted and stained to render the precipitin lines visible and finally dried flat between filter paper sheets at room temperature. The stains used were ponceau *S* (G. T. Gurr) (0·15 per cent in 3 per cent trichloracetic acid) for strong precipitin lines and dilute nigrosine *WS* (0·001–0·0025 per cent in 2 per cent acetic acid) for weaker lines as described by Kohn[3]. The membrane may be stained first with ponceau then with nigrosine. Examples of double diffusion on membranes are illustrated in Figs. 1*a* and 2*a*. Fig. 1*b* shows a conventional agar plate diffusion employing the same samples of antiserum and antigens as in Fig. 1*a*.

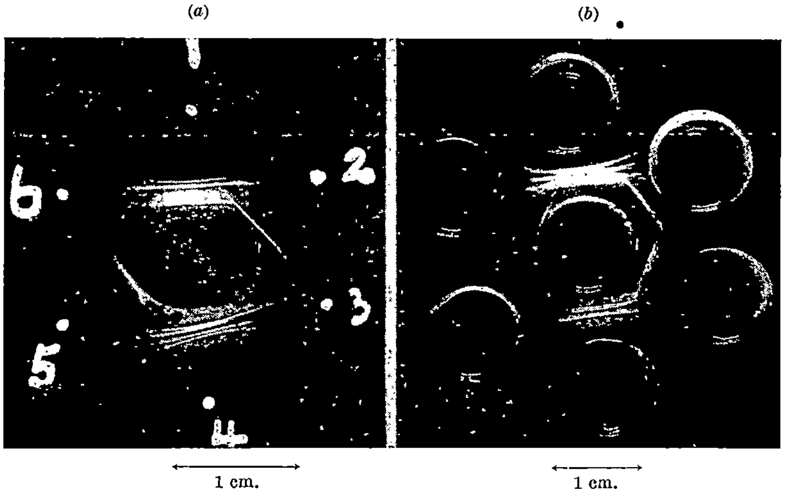

Fig. 1. (*a*) Double diffusion on cellulose acetate membrane at *p*H 7 for 2 days. Human serum or human serum fractions (2–3 μl.) placed at positions 1–6, horse anti-human serum at centre. Stained with ponceau *S*. Negative print from oil transparency. (*b*) Diffusion on agar with same samples (about 0·3 ml. in each well)

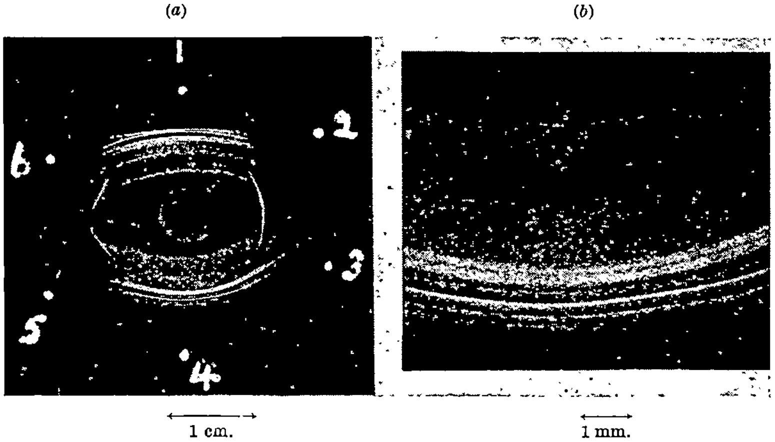

Fig. 2. (*a*) Diffusion on cellulose acetate at *p*H 8·6. Horse anti-human serum at centre. Normal human sera at positions 1 and 4. Concentrated urines from cases of myeloma at positions 2, 3, 5, 6. Stained with ponceau *S*. (*b*) Portion of membrane above position 4 in (*a*) enlarged direct from transparency

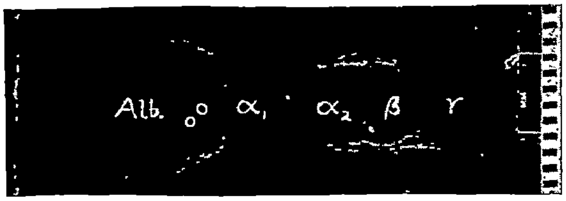

Fig. 3. Immuno-electrophoresis on cellulose acetate membrane (12 cm. × 2½ cm.). Electrophoresis of normal human serum (3 μl.) carried out at 20 V./cm. for 1½ hr. in barbitone buffer, *p*H 8·6. Horse anti-human serum placed along membrane above and below antigens after electrophoresis. Stained with nigrosine. Negative print from transparency

The stained membrane is best viewed in transmitted light, and may be photographed in this way. However, when soaked in 'Whitemor' oil, cellulose acetate, when dry, becomes almost transparent. The oiled, stained membrane if sandwiched between glass plates may then be used as a transparency for projection or for enlargement in a photographic enlarger. An enlargement of a small portion of a membrane is shown in Fig. 2*b* and demonstrates the fine nature and sharpness of the precipitin lines.

The Oudin-type of diffusion is carried out on a strip of cellulose acetate. Antigen and antiserum are each applied across the width of the strip about ½ in. apart. The strip is hung vertically in the oil during the diffusion stage.

For immuno-electrophoresis, the electrophoresis stage is carried out on the membrane strip as described by Kohn[1,3], the sample (1–5 μl.) being applied as a drop or across a short line at the starting position. After the electrophoresis, and without removing the strip from the box, a line of antiserum is applied from the capillary, preferably in one movement, parallel to the electrophoresis direction and at a distance of 0·5–1 cm. from the antigens. The lid is then replaced until the serum has soaked in, when the strip is removed to the oil bath. Subsequent procedures are as described above. Fig. 3 illustrates an immuno-electrophoretic pattern.

In these experiments diffusion under oil has been preferred to diffusion in a moist atmosphere, because in the latter conditions it is difficult during a long period to avoid unequal evaporation from the membrane surface which might cause artefact or distorted lines. The inert oil does not appear to have any denaturating effect on proteins.

Certain precautions should be observed in these techniques. No portion of the membrane should be allowed to become dry before transference to the oil bath. Should this occur, the membrane can be returned to the moist chamber and exposed until uniformly damp. All solutions and samples should be free from particulate matter, and the former should preferably contain a preservative to prevent bacterial growth; colonies of micro-organisms may cause distortion of precipitin lines and form an undesirable patchy background when stained. Membranes should be handled with forceps.

Cellulose acetate membranes have a number of advantages over agar. The material is relatively simple to use and satisfactory results are obtained with about 1/100 of the amounts usually used for gel diffusion (Fig. 1). In a membrane, precipitin lines can occur at the position of application of the samples but cannot form in the wells of an agar plate (Fig. 1). There is no difficulty in storing membranes. In jelly, of course, formation of the precipitin lines can be seen directly, whereas in a membrane they are not visible until stained. However, replicate diffusions may readily be carried out on membranes to establish optimum conditions, and, moreover, the material can be treated with a variety of dyes and reagents to obtain information about the chemical nature of the antigen in the precipitin lines. Cellulose acetate membranes are manufactured of standardized material in Britain, but a cellulose nitrate membrane has been found to be satisfactory for diffusion though not for electrophoresis. It is probable that other existing membranes may also prove suitable for one or both purposes.

ABSORPTION OF ALKALI CATIONS BY PLANT TISSUE CULTURES

By Dr. J. F. SUTCLIFFE and E. R. COUNTER

Department of Botany, King's College, London

It was observed by Steward and Millar[1] that actively growing carrot and artichoke tissue cultures absorbed cæsium ions more slowly per unit of fresh weight than did slowly growing cultures, and they concluded that, in general, the rate of uptake of salt is more rapid in vacuolated than in meristematic cells.

There were certain features of the experimental procedure which make it difficult to be sure that the differences observed were really due to the different physiological condition of the two types of tissue culture, as Steward and Millar suggested. Another possibility which occurred to us is that differences in the ionic composition of the two media employed may have been responsible for the effect. Although the concentrations of cæsium ions supplied were the same for each tissue (10^{-3} *M* and 10^{-5} *M*), the media were different with respect to the concentration of other ions because of the addition of 10 or 15 per cent coconut milk as a stimulant to the rapidly growing cultures. A sample of coconut milk which we analysed recently contained about 0·045 *M* potassium and 0·015 *M* sodium. The medium in which the slowly growing tissues were cultured contained about 0·0017 *M* potassium and 0·003 *M* sodium, and so it is evident that the composition of the two media, at least with respect to these ions, was quite different. Now it is well known that alkali cations compete with one another for absorption by plant tissues[2–4], and consequently it is to be expected that uptake of cæsium would be depressed by the presence of potassium and sodium; and to the greatest extent in the actively growing cultures where the concentrations of potassium and sodium in the medium were highest.

In order to test this possibility, we have repeated some of Steward and Millar's experiments using carrot explants placed in media with and without 10 per cent coconut milk, but with the initial potassium

Table 1. Cæsium Content (μequiv. per gm. fresh weight), and the Fresh Weight (gm.) of 3 Replicate Batches of 10 Cultures of (*A*) slowly growing and (*B*) actively growing Carrot Tissues, after 2 and 3 weeks at 23° C.

Treatment		After 2 weeks Fresh wt.	 Cs content	After 3 weeks Fresh wt.	 Cs content
	1	0·086	1·3	0·147	1·4
A	2	0·098	1·1	0·137	1·7
	3	0·083	1·5	0·121	1·7
	1	0·240	0·76	0·560	0·51
B	2	0·245	0·66	0·608	0·52
	3	0·245	0·80	0·576	0·51

and sodium concentrations adjusted to the same value in both media (0·01 *M* for each ion) by addition of appropriate amounts of potassium and sodium chlorides. Cæsium chloride, labelled with cæsium-134, was supplied in each solution at a concentration of 10^{-4} *M*. The results obtained are shown in Table 1.

It was observed that although the actively growing cells absorbed more cæsium per culture than the slowly growing tissues, they absorbed considerably less on a gm. fresh weight basis. The differences observed were much lower than those found by Steward and Millar, who reported a 14-fold difference in uptake per unit of fresh weight between the two kinds of cultures. It must be concluded that the bulk of the effect observed by these workers is attributable to the composition of the media they used, rather than to the differing absorptive abilities of rapidly growing and slowly growing tissues; nevertheless the growing cultures seemed in our experiment to be somewhat inferior in their accumulatory capacity.

It seemed to us important to establish that the last conclusion is a general one, applying to physiologically important cations as well as to cæsium. Therefore, in another similar experiment we measured the uptake of potassium and sodium ions by carrot tissues grown in culture media containing each of these ions at a concentration of 0·01 *M* in the presence and absence of coconut milk.

Table 2. Potassium (K) and Sodium (Na) Content (μequiv. per gm. fresh weight), and the Fresh Weights (gm.) of (*A*) slowly growing and (*B*) actively growing Carrot Tissue Cultures, in 2 and 3 weeks at 23° C.

	After 2 weeks		After 3 weeks	
	A	*B*	*A*	*B*
	(*S.E.*)	(*S.E.*)	(*S.E.*)	(*S.E.*)
Fresh wt.	0·075 ± 0·006	0·262 ± 0·018	0·103 ± 0·006	0·536 ± 0·005
K	104 ± 7·8	123 ± 5·0	128 ± 12·1	123 ± 3·7
Na	68 ± 7·1	15·6 ± 1·0	70 ± 4·7	21·5 ± 1·1
Ratio K/Na.	1·5	7·9	1·8	5·7

The results of this experiment (Table 2) show that untake of potassium per gm. fresh weight was not significantly different between the two treatments. Uptake of sodium, however, was considerably higher in the slowly growing than in the actively growing tissues. The ratio K/Na in the tissue remained fairly constant over the experimental period in the case of slowly growing tissues, but decreased with time in the actively growing cultures. It is clear from these results that actively growing cells exhibit a stronger preference for potassium over sodium than do slowly growing ones, but that the difference becomes less marked with time. One possible explanation is that in actively growing tissues, containing a higher proportion of meristematic and nearly meristematic cells, relatively more of the absorbed ions are retained by the cytoplasm than in the slowly growing, mainly vacuolated cells where the bulk of the salt is transferred to the vacuoles. Retention in the cytoplasm may depend to some extent on ion-binding to specific sites (for example, on enzymes) which exhibit a marked potassium preference, whereas vacuolar accumulation in carrot cells may be relatively unselective with respect to sodium and potassium. In support of the last statement we have found that the prolonged metabolic accumulation of cations by washed slices of dormant carrot tissues, which is presumably mainly vacuolar accumulation, does not exhibit any marked discrimination between potassium and sodium. By the end of 3 weeks culture, the rate of growth in the actively growing tissue was beginning to decrease, and this was probably accompanied by increased vacuolation, which may account for the reduction in the ratio K/Na absorbed with time.

In an attempt to distinguish more clearly between cytoplasmic and vacuolar accumulation in tissue culture cells, we have studied the uptake of potassium and sodium by growing red beet cells in which it is already known that vacuolar accumulation exhibits a preference for sodium over potassium[4]. Explants were cultured in three different media: (*A*) a basal medium containing salts and sugar; (*B*) basal medium + indole-3-acetic acid (5×10^{-5} *M*); (*C*) basal medium + 10 per cent coconut milk. In all treatments the concentrations of potassium and sodium were adjusted initially to 0·01 *M*. The tissues grew appreciably during the experimental period although not so rapidly as carrot tissue cultures. Microscopic examination indicated that the growth in *A* and *B* was mainly, if not entirely, by cell enlargement; whereas the growth in *C* was predominantly the result of cell division accompanied by a little cell expansion.

Table 3. Potassium (K) and Sodium (Na) Uptake (μequiv. per gm. fresh weight) and the Fresh Weights (gm.) of Beet Tissues after 2 weeks of Culture at 23° C. in (*A*) Basal Medium; (*B*) Basal Medium + Indole-3-acetic acid; (*C*) Basal Medium + Coconut Milk

		A	*B*	*C*
Fresh wt.		0·044	0·081	0·079
Uptake	K	17	26	79
	Na	161	126	94
Ratio K/Na		0·11	0·21	0·84

Salt analyses showed (Table 3) that tissues in the various media absorbed sodium in excess of potassium during the experimental period. Tissues in the medium containing coconut milk, however, showed a much smaller preference than did the tissues cultured in the other media, and this might be attributable to a partial masking of the sodium-preferring vacuolar accumulation by concomitant cytoplasmic accumulation exhibiting a preference for potassium.

These results, therefore, are consistent with the idea of a two-phase metabolic accumulation of cations into: (*a*) cytoplasm and (*b*) vacuoles of plant cells. In both beet and carrot tissue cultures the two components could be distinguished on the basis of selectivity, and it is of interest that cytoplasmic accumulation apparently exhibited a potassium preference even when vacuolar secretion was characterized by a strong preference for sodium. Possibly this is related to the metabolic utilization of potassium rather than sodium by the cells.

A full account of this work, which is now being extended, will be published elsewhere in due course.

LETTERS TO THE EDITORS

PHYSIOLOGY and BIOCHEMISTRY

The Work Output of Animals: Flight by Birds and by Man-power

MEN have always wanted to fly by their own power, like birds. But man is five times heavier than the heaviest flying creature of this or any other epoch. This creates difficulties; for as birds increase in size, their wing area diminishes in relation to their weight, since geometrical configuration and density remain roughly the same. This effect can only be countered by a greater expenditure of mechanical power by the larger specimens. In fact, the power required for level flight increases as $(\text{weight})^{1\cdot167}$ (Nonweiler, 1957, private communication).

Imagine a set of flying machines having the same shape and density, but differing in size. Let L be a characteristic length, and let V be the forward speed: then both lift and drag are proportional to V^2L^2. To achieve flight, weight = lift. Thus $L^3 \propto V^2L^2$, so that $V \propto L^{0\cdot5}$. Power expended = speed × drag $\propto V.V^2.L^2 \propto L^{3\cdot5} \propto (\text{weight})^{1\cdot167}$.

Successful aeroplanes have been built that range in size from a few grams up to nearly 200 tons. This is possible because artificial sources of power are available which provide considerably more power than is needed merely to achieve flight. Internal-combustion aero-engines are available with a weight range of $1:10^5$, and they all produce about 1·5 horsepower per kilogram. Full-sized engines actually become more powerful as they become bigger; their power goes up roughly as their $(\text{weight})^{1\cdot28}$.

But what of living creatures? What is their power output, and how does it vary with their size?

The Power Output of Animals is small compared with that of petrol engines of similar weight. For example, the maximum continuous power output of an athletic man is only 0·5 per cent of the output of an engine of comparable weight.

One of the best-established facts of comparative physiology is that the resting metabolism of animals varies with their size in an exceedingly regular manner. The smaller the animal, the greater its resting metabolism per kilogram. This is illustrated in line A of Fig. 1. The black spots represent actual measurements of the resting energy output of dogs, men, and horses. They are extracted from the much larger series of measurements on mammals and birds (from mice to elephants, a range in weight of more than five decades) collected by Brody (ref. 1, pp. 370, 388). He showed that these measurements could be fitted by the equation:

resting metabolism in h.p. = $4\cdot6 \times 10^{-3}$ (weight in kgm.)$^{0\cdot734}$

Line A is drawn from this equation.

Now, an animal at rest is doing no external work, its energy output is all in the form of heat. We want to know what happens when it *is* performing external mechanical work. This is not easy to investigate experimentally. Most animals can be lulled to rest, but few can be induced to work steadily and energetically. Moreover, the mechanical work must be performed in such a way that it can be measured. The final difficulty, which is almost psychological, is that a valid comparison can only be made between animals that are trying equally hard to perform comparable tasks.

The only measurements that I have been able to find in which all these criteria were satisfied were on dogs climbing a treadmill[2] or pulling a sledge[3]; men cycling, rowing, climbing, etc; and horses pulling[1].

In each case it is possible to fit a reasonably good straight line to the points which is parallel with line A. This shows that the output of mechanical work varies with size in exactly the same way as does the resting metabolism, and helps to support Brody's claim that one can express the effort that an animal is exerting as a multiple of its resting metabolism. Lines B, C and D correspond to mechanical power outputs of 1·7, 4·8 and 25 times basal heat production. Because of the relative inefficiency of muscular contraction, the total production of energy (work + heat) resulting from exercise will be about four times greater, say, 7, 20 and 100 times basal. The conclusion to be drawn is that the maximum metabolic rate is linked to the resting metabolic rate; though it is not clear what the physiological mechanism of this link may be.

We are now in a position to appreciate the dilemma of the birds that tended, in the course of evolution,

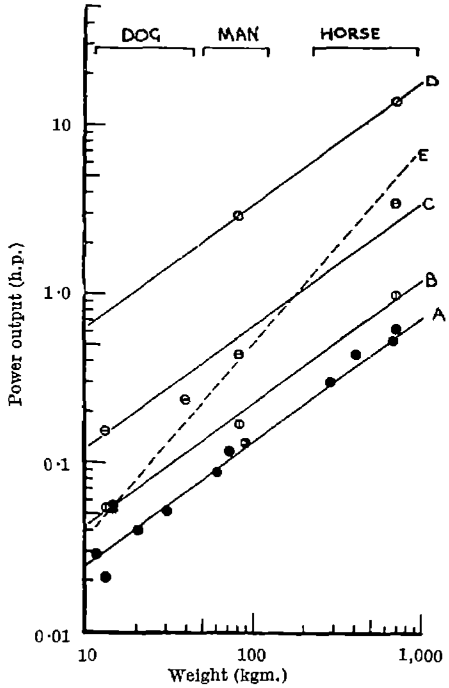

Fig. 1. Power output of animals as a function of body-weight; plotted on a double logarithmic scale. A (black spots), heat output at rest; B, C, D (circles), work output at various levels of effort; B, maintained all day; C, maximum steady-state (maintained 5–30 min. approximately); D, brief effort (maintained a few seconds only, by going increasingly into oxygen debt). The full lines have been fitted from the equation: horse-power = const. 10^{-3} (kgm.)$^{0\cdot734}$, where const. is 4·6, 7·4, 21 and 113 respectively; E (dashed line) shows the power required to fly, calculated from the relation:

$$\text{horse-power} = 2\cdot33 \times 10^{-3}\,(\text{kgm.})^{1\cdot167}.$$

* Intersection of B and E represents the great bustard.

to become larger. As they did so their power production (lines *B*, *C*, *D*) became relatively less, while their power requirement (line *E*) increased. Evidently flying ceased to be a practical proposition for birds heavier than about 15 kgm. This is not to say that it is impossible; merely that it is too expensive a means of transportation for a bird in a competitive world.

Line *E* has been drawn with the theoretical slope derived from the relation:

$$(\text{power required}) = \text{const. } (\text{weight})^{1\cdot167}$$

but in order to fix the position of the line it is obviously necessary to estimate the value of the constant. This involves estimating, or guessing, the power output of a bird of known weight. I have chosen the great bustard, because, at 14·5 kgm. it is the heaviest flying bird. It is said to be capable of powerful and sustained flight, so I have assumed that it can fly with its 'all-day' level of effort (line *B*) and have accordingly made line *E* intersect *B* at 14·5 kgm.

Fig. 1 then leads to the interesting conclusion that it should be possible for birds weighing up to 170 kgm. to fly while still remaining in oxygen balance, though they would have to work extremely hard to do so. Line *E* passes just below the maximum steady-state point for a man; so if he had wings he would be able to fly. Unfortunately, in practice, flying machinery will have to be carried as an extra—the extra weight per man (assuming a two-man machine) can scarcely be less than 40 kgm. This may mean that man can only fly by incurring an oxygen debt, which would limit the performance to a few minutes.

These conclusions, based on comparative and dimensional grounds, entirely agree with those of Nonweiler[4], who has calculated in a purely aerodynamic design-study the power needed for flight by a suitable aircraft, and compared this with the known power output of man. They disagree with the conclusions of Günther and Guerra[5], who assumed in their calculations that the power required for flight increased as $(\text{weight})^{0\cdot667}$.

Calculation thus indicates that practical man-powered flight is possible, but only just possible, so that good engineering will be needed to achieve it. Clearly, the matter should be put to experimental test.

Fast and Slow Muscles in Mammals

THE histology and physiology of both fast and slow types of cat striated muscle were studied in detail by Denny-Brown[1]. He reported that the histological appearance did not distinguish definitely between the functionally fast and functionally slow type of muscle fibre. From his physiological investigations he concluded that the typically fast muscles (for example, gastrocnemius) were specialized for phasic contractions, whereas the typically slow muscles (for example, soleus) were utilized for tonic contractions. He suggested that a comparable arrangement of fast gastrocnemius and slow soleus might be found in many animals, including man.

The renewed interest in the physiology of fast and slow contracting muscles[2] has prompted an attempt to measure the contraction times in human muscles. The responses of the gastrocnemius and soleus muscles were examined in sixteen normal males between the ages of 18 and 40 years, some repeatedly. The subjects were examined while lying at rest in the prone positions. The muscle contraction was recorded by means of a saline-filled needle inserted into the belly of the muscle and connected to a capacitance manometer measuring the pressure among the fibres. The muscle fibres lying adjacent to the recording needle were caused to contract by an electrical stimulus applied either via the recording needle itself, or via a second needle placed in close proximity to the first. Thus the pressure changes within a group of contracting muscle fibres were measured. When this technique was used in the muscles of the cat and the results compared with simultaneous measurements of tension changes using the conventional strain gauge, it was found that, although it did not accurately record the time-course of the contractile process, nevertheless the method adequately differentiated the fast and slow muscles of the cat as shown in Fig. 1.

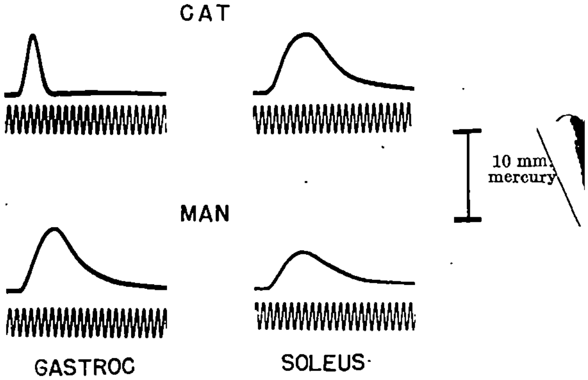

Fig. 1. Top row: Records obtained with a capacitance manometer of the pressure among a group of contracting fibres of gastrocnemius muscle (time to peak, 35 msec.) and soleus muscle (time to peak, 110 msec.) of the cat. Bottom row: Records obtained by similar recording from a human subject. Time, 50 c./s. Pressure, 10 mm. mercury

In the human subjects, no such clear-cut distinction could be made between the times of contraction of gastrocnemius and soleus. While the average time to peak of gastrocnemius contractions (110 msec., range 92–150 msec.) was somewhat shorter than that of soleus (120 msec., range 100–150 msec.), no regular pattern emerged, and in any one subject the times of contraction of the two muscles often differed by less than 20 msec.

In preliminary studies of human muscles other than those of the calf (forearm and hand), it was noted that considerably shorter times of contraction than with soleus and gastrocnemius could be obtained, but so far none shorter than 45 msec. to peak.

It therefore appears that, contrary to Denny-Brown's suggestion, the clear-cut differentiation of gastrocnemius and soleus into fast- and slow-contracting muscles respectively does not occur in the human.

Effect of Monofluorosulphonate, Difluorophosphate and Fluoroborate Ions on the Iodine Uptake of the Thyroid Gland

Several inorganic anions have been found to interfere with the normal function of the thyroid gland[1-3], the perchlorate and thiocyanate ions being outstanding in this group. On the other hand, it has been shown that other common anions, including chloride, bromide, fluoride, sulphate, phosphate and bromate ions, have no significant effect on the iodine uptake and retention in the gland. The effect of perchlorate ions suggests a competition for some sites in the thyroid[1]. This assumption is supported by the fact that perchlorate ions concentrate in the gland[4]. Further, it was shown[4] that perchlorate ions do not undergo metabolization, thus excluding the possibility that they are involved in some enzymatic redox system. This behaviour of the perchlorate ion distinguishes it from other inorganic thyroid blocking agents like thiocyanate ions which have been shown to be metabolized and not to accumulate in the gland[2]. It occurred to us that the competition between perchlorate and iodide ions may be due to their similar monovalency and size. It is hard to compare the size of a spherical ion like iodide with that of a tetrahedral complex ion like perchlorate. Still we may compare the calculated volumes. The volume of ClO_4^- may be calculated taking $r(O^=) = 1{\cdot}33$ A. From the radius of I^-, $r(I^-) = 2{\cdot}16$ A., we may find its volume. We find for the volumes of ClO_4^- and I^- the values 3·94 and $4{\cdot}23 \times 10^{-23}$ cm.^{3} respectively. The experimental value[6] for the ionic volume of ClO_4^- is $4{\cdot}05 \times 10^{-23}$ cm.^{3}.

In order to check the hypothetical correlation between ionic size and its effect on the thyroid function, three ions which are isoelectronic with and of almost the same size as ClO_4^- were chosen. The similarity between perchlorate, monofluorosulphonate, difluorophosphate and fluoroborate ions has been pointed out[6,7]. The similarity of the ionic sizes of these ions may be deduced from the values of the bond-lengths in ClO_4^- (r(Cl—O) = 1·50 A.)[6], in sulphate (r(S—O) = 1·50 A.)[6], in phosphate (r(P—O) = 1·50 A.)[6] and in fluoroborate (r(B—F) = 1·48 A.)[8], and, on the other hand, from the fact that[5] $r(O^=) = r(F^-)$. In our experiments we compared, under identical conditions, the effects of the three ions mentioned above with that of perchlorate on the accumulation of iodine in the thyroid.

Monofluorosulphonate and difluorophosphate were synthesized by the reaction of ammonium fluoride with sulphur trioxide and phosphorus pentoxide respectively[9]; they were separated and purified by precipitation of their corresponding nitron complexes and finally their ammonium salts were recrystallized. Potassium fluoroborate was prepared from commercial fluoroboric acid and was recrystallized before use.

0·1 ml. of a 1 per cent solution of propylthiouracyl was injected into young rats (100–110 gm.) intraperitoneally, in order to block the formation of protein-bound iodine in the gland[3]. 1 hr. after this injection, 0·1 ml. of carrier-free iodine-131 iodide solution (40 mc./ml.) was injected. 15 min. later an injection of 0·5 ml. saline containing 25 μmoles of $KClO_4$, NH_4SO_3F, $NH_4PO_2F_2$ and KBF_4 respectively was given. The control rats were injected with 0·5 ml. of pure saline. The rats were killed at intervals of 30, 60, 90 and 120 min. after the iodide injection. The whole thyroid gland was removed and 1 ml. fresh blood was measured volumetrically and taken as a reference. The activity of the thyroid glands and of the blood samples was determined in a well-type sodium iodide scintillation counter. A summary of our experimental results is presented in Tables 1 and 2.

From the experimental results it is evident that all four ions tested are effective at these low concentrations. The increase in uptake with time of the $PO_2F_2^-$ series is most probably due to the hydrolysis of this ion[9] to F^- and $PO_4H^=$, which are not effective as inhibitors of iodide uptake[1]. It should be noted that these thyroid blocking agents have an effect within 15 min. after injection.

Other substances which accumulate in the thyroid, and thus interfere with its normal function, have been described lately, namely, TcO_4^- and ReO_4^-. Their accumulation in the thyroid was attributed to their position in the Periodic Table[10]. Evaluating the ionic volumes of these ions, we find[6] that the values for MnO_4^- and ReO_4^- are 4·0 and $4{\cdot}1 \times 10^{-23}$ cm.^{3} respectively; we may therefore infer that the ionic volume of TcO_4^- is $4{\cdot}05 \times 10^{-23}$ cm.^{3}, which actually is the experimental value found for the ionic volume of ClO_4^-. Thus we may include TcO_4^- and ReO_4^- in our series of effective monovalent anions.

It is worth while pointing out a correlation between the uptake of certain anions by the thyroid proteins and the fact that these very ions form insoluble complexes with nitron (1,4-diphenyl-3,5-endanilo-

Table 1. Activity of the Thyroid Glands (Counts/Min./Whole Thyroid)

* Taking the average weight of a rat's thyroid as 12 mgm. we may calculate the relative specific activity of the thyroid by multiplying the relative activity of the whole thyroid given in Table 2 by 833

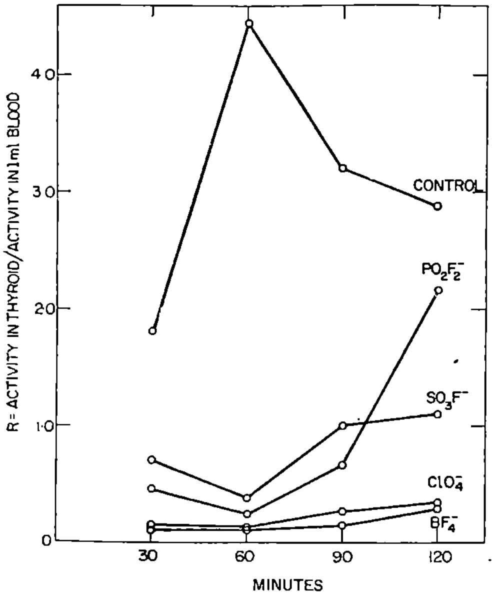

Fig. 1. Relative activity of thyroid glands of rats injected with inorganic blocking agents

4,5-dihydro-1,2,4-triazole). These ions include not only perchlorate and its isoelectronic species but also iodide, thiocyanate, chlorate and nitrate; all of them were found to take part in the function of thyroid[1]. The striking fact is that whereas chlorate has some effect on iodide uptake, no such effect was found for bromate[1]; it has been shown that iodate does not accumulate in the thyroid[11]. It has been shown[12], moreover, that nitron does not form insoluble complexes of appreciable stability with iodate and bromate.

It may be concluded that the trapping mechanism in the thyroid involves a factor which scarcely distinguishes between different anions having the same charge and a comparable volume. Such a factor is probably a protein with a special arrangement which traps only those ions which fulfil these requirements.

In Vitro Effects of Insulin and Glucose on Leucine-2-^{14}C Incorporation into Protein of Diaphragms of Hypophysectomized Rats

INSULIN, added *in vitro*, has been found to stimulate the incorporation of labelled amino-acids into the protein of isolated diaphragms of normal rats[1-4]. Glucose, when added to the incubation medium, depressed the stimulatory action of insulin on the uptake of alanine labelled with carbon-14 [1,3] and α-amino*iso*butyric acid-^{14}C [4] by normal diaphragm. Even when insulin was not added to the incubation medium the uptake of these amino-acids was markedly depressed by supplementing the medium with glucose. In one report, however, the incorporation of glycine labelled with carbon-14 into protein of diaphragms of normal fasting rats was found to be increased by the addition of glucose alone to the medium[2]. A later study[3] failed to confirm this observation and indicated further that neither glucose nor pyruvate seriously altered the uptake of a number of amino-acids labelled with carbon-14 by normal diaphragm. From the above studies it was apparent that insulin had a stimulatory effect on the uptake of amino-acids by isolated muscle of normal rats, and that in certain instances this effect was altered by the concomitant utilization of carbohydrate. Thus, it was of interest to study the effects of insulin and of glucose, alone and in combination, on the *in vitro* incorporation of labelled leucine by the diaphragm of hypophysectomized rats, which show a decreased rate of incorporation of amino-acid[5] but which utilize glucose at a greater than normal rate[6].

Female rats (60 gm.) that were hypophysectomized three weeks previously were killed by a blow on the neck, and the diaphragm was quickly excised with part of the rib cage and spine attached and placed in freshly gassed buffer. The diaphragm was then divided into two hemi-diaphragms by cutting through the central ligament and through the insertions to the xiphoid process and spine. Each hemidiaphragm with ribs attached was blotted and placed in a 50-ml. Erlenmeyer flask and incubated with shaking for 90 min. at 37° C. The incubation flasks contained 6 ml. Krebs–Ringer phosphate buffer, *p*H 7·4, to which DL-leucine-2-^{14}C was added at a concentration of 0·1 m*M* (25,000 c.p.m./ml. medium). Each flask was gassed with 100 per cent oxygen during the first 2 min. of incubation and then sealed. Insulin (Lilly, crystalline, No. *T*-2842) was added to the medium at a concentration of 0·5 U./ml. and glucose was added at a concentration of 2 mgm./ml. medium. The incorporation reaction was terminated by rapidly chilling the flasks to 0° C. The tissue was then spread on a block of ice and the diaphragm muscle carefully trimmed of ribs and adhering tissue. The protein of the diaphragm was prepared and counted by methods published elsewhere[5].

The results are presented in Table 1. Insulin, added *in vitro*, increased the incorporation of leucine-2-^{14}C into the protein of diaphragms of hypophysectomized rats. Glucose added alone to the medium did not alter the incorporation of leucine by the diaphragms. Another experiment (not given in Table 1) with glucose added alone was carried out over a range of incubation times of 30–150 min., and again glucose addition had no effect on incorporation of leucine. When glucose and insulin were added together to the medium, the incorporation of leucine by the protein of the diaphragms was increased, but

Table 1. *In vitro* Effect of Insulin and Glucose on Incorporation of Leucine-2-^{14}C into Protein of Hypophysectomized Rats

Added to medium	No. of observations	c.p.m./mgm. protein	
		Mean	*S.E.*
Control	6	189	± 12·6
Insulin	6	287*	± 12·1
Glucose	6	186	± 22·4
Insulin + Glucose	6	280*	± 16·3

* Mean is significantly different from control, $P < 0{\cdot}01$.

the increment was similar to that produced by insulin alone (Table 1).

These results indicate that insulin *in vitro* stimulated the incorporation of labelled leucine into the protein of diaphragms of hypophysectomized rats. The addition of glucose to the medium, in the presence or absence of added insulin, had no effect on this system. These results agree qualitatively with those obtained in experiments with normal rat diaphragms[3]; but the increase in leucine incorporation produced by insulin in the hypophysectomized rat diaphragm (151 per cent of control) was greater than that reported for diaphragms of normal rats (118 per cent of control). The lack of an effect of glucose on this system would favour the opinion expressed by Manchester and Young[3] that the action of insulin in stimulating amino-acid incorporation is largely independent of its action on carbohydrate metabolism.

It is of interest that, like insulin, chronic bovine growth-hormone treatment begun seven days post-operatively resulted in a stimulation of *in vitro* leucine incorporation by diaphragms of hypophysectomized rats[5]. It is possible that this stimulation of amino-acid incorporation produced after growth-hormone treatment was due in part to an elevated insulin activity in the isolated diaphragm resulting from an increased secretion of insulin brought on by growth-hormone treatment. This seems unlikely, however, since bioassays of plasma insulin activity have failed to detect an increase in insulin activity when growth-hormone treatment was given to hypophysectomized rats 7–9 days post-operatively[7]. Moreover, growth hormone injected into hypophysectomized rats 18–24 hr. before removal of the diaphragm lowers the insulin activity bound to this tissue, as assayed by glucose uptake[8].

This study was conducted during the tenure of a National Research Fellowship in the Medical Sciences and was supported by a grant from the American Cancer Society (*P* 139-*A*) made to Dr. E. Knobil. I wish to thank Dr. Knobil for helpful criticism and Dr. Mary Root of Eli Lilly and Co. for generously supplying the crystalline insulin.

Effect of Norleucine and Related Compounds on Growth of the White Rat

It was recently reported from this laboratory that the inclusion of 2 per cent DL-norleucine in the diet greatly inhibited the utilization of D-leucine by rats[1]. In view of this observation it was of considerable interest to determine whether the antagonistic effect of norleucine on leucine utilization was limited to the D-isomer of the latter.

The experiments summarized in Table 1 were designed to compare the effect of leucine isomers on the reversal of norleucine toxicity. Weanling albino rats of the Yale strain which were previously fed on a nitrogen-free diet for a 2-week period were used in this study. Following this period the animals were fed an amino-acid diet containing various levels of L- and D-leucine in the conjunction of 2 per cent DL-norleucine, as outlined in Table 1. The composition of the basal diet and the amino-acid mixture have been described elsewhere[2]. It can be seen from Table 1 that both enantiomorphs of leucine are antagonized by norleucine, but it is also apparent from the results that the antagonism is greater in the case of D-leucine. Although the exact quantitative relationship was not determined, it appears that at least twice as much of D-leucine is required to reverse norleucine toxicity when compared with the L-isomer. This is in good agreement with the previous observation that L-leucine is approximately twice as effective as the D-leucine for growth of young rats[2]. Note the close correlation between water consumption and growth.

Although norleucine does not seem to be a natural constituent of proteins[3] it is readily metabolized by mammals[4–7]. When incubated with rat liver homogenate it gives rise to α-ketocaproic acid, valeric acid and β-hydroxyvaleric acid. On the basis of such results, Kinnory *et al.*[8] concluded that norleucine is catabolized by conversion to the corresponding α-keto-acid, followed by oxidative decarboxylation and the subsequent oxidation to the resulting monocarboxylic acid by β-oxidation.

In order to learn more about the growth-depressing effect of norleucine an additional study was undertaken in which two of the above-mentioned intermediates of norleucine catabolism (α-ketocaproic and valeric acids) and two other compounds closely related to norleucine (caproic and ε-aminocaproic acids) were compared with norleucine for their effect on growth of rats. Since the growth-retarding effect of norleucine was previously demonstrated with the diet containing L-leucine at a level corresponding to 50 per cent of the requirement, that is, 0·43 per cent of the diet, it was decided to use this amount of L-leucine in our control diet. The compounds under test were added to the diet at molar equivalent levels corresponding to 1 per cent of norleucine. Normal weanling male albino rats of the Sprague–Dawley strain were used for assaying the above compounds. Each experiment covered 2 weeks. The experimental results which are shown in Table 2 demonstrate that of all the substances tested only norleucine and α-ketocaproic acid retarded the growth of rats. The slower rate of growth of animals was accompanied by lower consumption of food and decreased food efficiency. The inhibitory effect of the keto-acid is not unexpected since the first major step in the catabolism of most amino-acids, that is, formation of keto-acid, is readily reversible[9]. Since the keto-acid was less inhibitory than norleucine, while valeric acid

Table 2. EFFECT OF NORLEUCINE AND RELATED COMPOUNDS ON THE GROWTH OF WEANLING RATS FED DIETS LOW IN LEUCINE

Supplement to leucine-free diet	No. of rats	Initial weight (gm.)	Average weight gain (*W*) (gm.)	Average food intake (*F*) (gm.)	*W*/*F*
0·43 per cent L-leucine	4	57	16·0	71·5	0·22
0·43 per cent L-leucine + 1·0 per cent DL-norleucine	4	57	5·3	57·5	0·09
0·43 per cent L-leucine + 2·0 per cent DL-norleucine	4	57	2·0	62·0	0·03
0·43 per cent L-leucine + 0·99 per cent α-ketocaproic acid	4	57	8·5	56·0	0·15
0·43 per cent L-leucine + 0·78 per cent valeric acid	4	57	16·0	61·5	0·26
0·43 per cent L-leucine + 0·89 per cent caproic acid	4	57	19·3	73·5	0·26
0·43 per cent L-leucine + 1·00 per cent ε-aminocaproic acid	4	57	15·3	69·0	0·22

was without any demonstrable effect, it can be concluded that the deleterious effect manifested by norleucine is due to the intact molecule of the latter rather than to some of its catabolic products. Once the amino-acid undergoes oxidative decarboxylation it loses its growth-depressing effect. Since neither caproic nor ε-aminocaproic acids affected the growth of animals it is apparent that the amino- or oxo-group must be present at the α-carbon position in order to produce a growth depression in rats.

Formation of Urea from Arginine in the Brain of the Living Rat

IN a classical set of experiments, Bollman, Mann and Magath[1] demonstrated that "the production of urea in the body of the dog is entirely dependent on the presence of the liver, since urea formation ceases completely as soon as the liver is removed". Standard text-books of physiology and biochemistry have interpreted the above experiments as demonstrating that urea formation occurs exclusively in the liver. However, an alternative interpretation is possible, namely, that normal liver function is necessary for normal extra-hepatic metabolism, and such extra-hepatic metabolism may include urea synthesis. In fact, it has been shown that perfused brain requires factors elaborated or released by the liver to maintain normal metabolism[2].

Recently, our laboratory has demonstrated that the brain of the rat can metabolize proline to ornithine and arginine *in vivo*[3]. Because of the role of ornithine and arginine in the Krebs urea cycle[4], it was of interest to determine whether brain is capable of metabolizing arginine to urea. The present report describes such experiments.

In studying metabolism of the brain of the intact animal it is essential to control the variable of extra-cerebral metabolism if one wishes to draw valid conclusions about cerebral pathways. In order to control the variables (1) extra-cerebral metabolism and (2) alterations in the metabolism of the brain and in the permeability of the blood-brain barrier resulting from an intracisternal injection, the rats used in these experiments were injected as follows: rats 2 and 4 were injected intracisternally with 1·2 mgm. of uniformly labelled ^{14}C-L-arginine monohydrochloride (total activity 37 μc.); 5 min. after their intracisternal injections these same rats were injected in the exposed femoral vein with 1·2 mgm. of inert L-arginine monohydrochloride. Rats 1 and 3 (litter mates, respectively, of rats 2 and 4) were injected intracisternally with 1·2 mgm. of inert L-arginine monohydrochloride, and 5 min. later were injected in the exposed femoral vein with 1·2 mgm. of uniformly labelled ^{14}C-L-arginine monohydrochloride (total activity 37 μc.). If, by the use of the above method, one can show that rats 2 and 4, which received radioactive arginine intracisternally, have more radioactivity in urea isolated quantitatively from brain than rats 1 and 3, which received the same dose of radioactive arginine intravenously, then one may conclude that the brain itself has the ability to metabolize arginine to urea.

All injections were performed under light ether anæsthesia, and all rats were alert and walking within a few minutes after injections were finished. The animals were killed by decapitation 1 hr. after their injection of radioarginine, and their brains homogenized in trichloracetic acid. Following the addition of 8 mgm. of inert carrier urea, the homogenates were centrifuged and urea was isolated from

Table 1. RADIOACTIVITY IN BRAIN 1 HR. FOLLOWING INJECTION OF RADIOACTIVE ARGININE. ALL ACTIVITIES EXPRESSED AS COUNTS PER MIN.

	Rat 1	Rat 2	Rat 3	Rat 4
Brain (wet weight, gm.)	1·680	1·750	1·750	1·760
Total activity of injected arginine	27×10^6	27×10^6	27×10^6	27×10^6
Total activity of brain trichloracetic acid-soluble fraction	$2\cdot9\times10^4$	810×10^4	$4\cdot2\times10^4$	810×10^4
Activity/mgm. of dixanthydryl urea isolated from brain	43	1,500	46	1,710
Total activity in brain urea	2,600	89,000	2,700	101,000

the fractions soluble in trichloracetic acid by chromatography on 'Dowex 50' columns. Complete separation of urea from other components soluble in trichloracetic acid was achieved by making the dixanthydryl derivative of urea, which was then recrystallized to constant specific activity.

The results presented in Table 1 show that dixanthydryl urea isolated from rats 2 and 4 is 35–37 times more radioactive than that isolated from their litter-mate controls, rats 1 and 3. The results thus indicate that brain can form urea from arginine. Since it has previously been demonstrated that rat brain can synthesize arginine from proline[3], it appears that brain is capable of urea synthesis *in vivo*. However, the quantitative significance of this pathway as a method of ammonia detoxication in brain is not yet known, and the role of urea synthesis in the metabolism of the brain remains to be determined.

We wish to express our appreciation to Dr. John Romano and Dr. George L. Engel for their support and encouragement during these experiments. Miss Ailene Williams contributed valuable technical assistance. This work was supported by grant *M*–1901 from the National Institute of Mental Health, U.S. Public Health Service and by the Foundations' Fund for Research in Psychiatry. A more detailed report of these investigations will appear elsewhere[5].

Seasonal Variations in the Pituitary Gland of the Ferret

IT has been shown that the pars distalis of the pituitary gland of the cat, rabbit[1] and dog[2,3] contains cells which stain with carmine or acid fuchsin. These cells have been described as a second type of acidophile. They appear during the first pro-œstrous period in the young female cat, extend to occupy larger areas during œstrus and then partially regress[4].

Examination of the pituitary glands of female ferrets has shown that a similar type of carmine or fuchsin-staining cell is present, in addition to ordinary acidophiles which stain with orange *G* alone. After staining by the periodic acid – Schiff – orange *G* method[5] these 'carmine' cells appear deep reddish-orange in colour, in contrast to the yellow-orange of the acidophiles. This colour difference is due to a faint periodic acid – Schiff-positive reaction in the cytoplasm of the 'carmine' cells, combined with an affinity for orange *G*.

Pituitary glands of female ferrets killed at varying times of the year, and hence at varying phases of the breeding cycle, showed variations in the size and number of these cells. They were most numerous and widely distributed throughout the pars distalis in the glands of animals killed during early œstrus, and in four others which were anœstrous when killed in February, but which had been exposed to 16-hr. illumination each day for the three weeks before death. Bissonnette[6] showed that anœstrous ferrets reach full œstrus 38–64 days after exposure to extra light, and these four animals can almost certainly be considered to have been in an early pro-œstrous phase. In late œstrus, or early anœstrus, the cells were less conspicuous and reduced both in size and number; while in animals killed several months after the end of œstrus (November–January) the cells were either completely lacking or present only in small scattered groups. Vacuolation of the cells was seen in some, but not all, animals killed between August and December.

In the period immediately before œstrus, the cells are the largest of the various types in the pars distalis, and a Golgi zone similar to that found in basophiles is present in some of them. It seems probable that the increased size and number of these cells in the pro-œstrous period indicates that they are most active at this time; and this further suggests that they may be concerned with the initiation of œstrus.

Measurements of Oxygen Tension in the Tissues of Mice cooled to 1° C.

Evans, Goodrich and Slaughter[1] demonstrated a decrease in the sensitivity to X-irradiation of the skin of new-born rats at body temperatures of about 0° C. Increased resistance to doses of X-rays which were lethal at normal body-temperatures has been demonstrated[2–3] at about 1° C. Weiss[4] has shown that there is increased resistance to radiation in the testes of mice subjected to whole-body X-irradiation at body-temperatures in the region of 1° C. It has been suggested by all of these authors that profound hypothermia acts by virtue of the anoxia which follows respiratory and cardiac arrest, and it is known that anoxia reduces sensitivity to X-irradiation[5].

We have recently attempted to measure oxygen tensions in the organs of mice while cooling, when

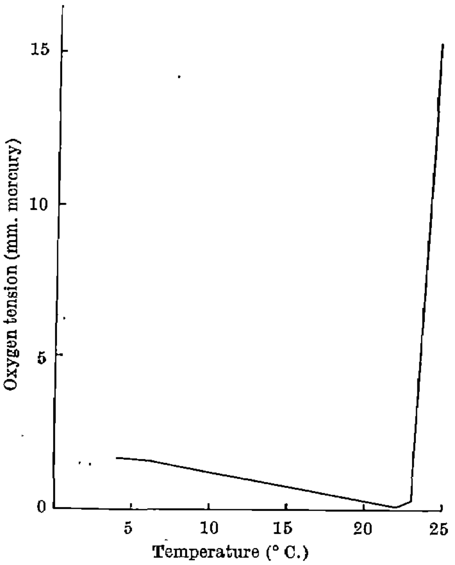

Fig. 1. Oxygen tensions recorded in the testis of a mouse resuscitated from 4° C.

cold, and also during resuscitation from the hypothermic state by the method of Goldsveig and Smith[6]. Gold electrodes (0·315 mm. diameter) insulated with 'Araldite' were inserted into spleen, testis and bone marrow and held in position by a stitch. A negative potential was applied (0·6 V. compared with a silver/silver chloride electrode inserted subcutaneously) and the resulting current was measured. Details of this oxygen–cathode technique for making quantitative measurements of oxygen tension will be described elsewhere (Cater, D. B., Silver, I. A., and Wilson, G. M., unpublished work).

Mice were cooled in sealed 1-lb. 'Kilner' jars immersed in ice, for 50 min. They were then removed from the jars, wetted with a detergent and surrounded by chipped ice, until their body temperatures measured per rectum fell to 0–1° C. After insertion of the electrodes, the ice was removed, the animals were warmed with a 60-W. electric light bulb, and given artificial respiration with a hand-pump.

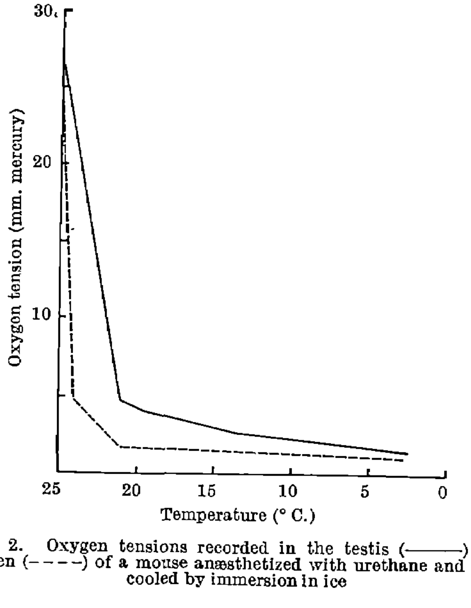

Fig. 2. Oxygen tensions recorded in the testis (———) and spleen (– – – –) of a mouse anæsthetized with urethane and then cooled by immersion in ice

The oxygen tensions recorded in the testis of a mouse, resuscitated from 4° C., are shown in Fig. 1. This experiment was discontinued when the animal showed signs of recovering consciousness.

It was not technically possible to make recordings of the oxygen tension in the organs of animals while they were being cooled down in a jar. However, mice were anæsthetized with subcutaneous injections of 25 per cent urethane in saline (0·25 ml./25-gm. mouse), and after the insertion of electrodes were cooled down in ice to 0–1° C. The recordings from the testis and spleen of such an animal are shown in Fig. 2. Respiration stopped in this mouse at 12° C.

The results showed that during cooling to the region of 0° C., the oxygen tension within the testis, spleen, bone-marrow and peritoneum fell reversibly to the order of 2 mm. mercury. This degree of hypoxia would be expected to afford considerable protection against radiation. The animals are protected from the effects of the hypoxia itself by their profound hypothermia. The possible applications of this to the radiotherapy of tumours will be discussed by one of us (L. W.) elsewhere.

Target Organ Activation by Stress

It is a well-established fact that under stress conditions the organism calls for increased corticosteroid activity[1]. The response to such a call has been believed to occur solely by an increased corticosteroid production, that is, by increased pituitary-adrenocortical activity. Recent studies[2,3] have brought to light certain facts which suggest that the organism possesses an additional mechanism to meet the increased demand for corticosteroid activity. This mechanism functions by increasing the sensitivity of the target organs to corticosteroids.

The possibility of such a mechanism emerged during a study of the action of topically applied corticosteroids upon skin capillaries. It was noted that capillary resistance, measured by the negative pressure method, may increase under the local influence of corticosteroids in what appeared at first a haphazard manner. Further observation indicated that this increase in the response of the capillaries to corticosteroids is, in fact, a stress phenomenon.

An ointment containing 0·5 per cent Δ^2-hydrocortisone was applied on a circumscribed skin area of the flexor surface of the arm in human subjects or on the abdomen of dogs. The ointment base only was applied in the same manner on an adjacent control area. Five hours later the resistance of the

capillaries was measured in both areas (the value of capillary resistance is the least negative pressure expressed in cm. mercury which can produce one or more petechiae by rupturing the capillaries of the skin area tested). It was found that so long as the experimental subjects (two healthy volunteers and eight dogs) were leading a routine life and avoiding any extra stressful activity there was no difference between the resistance of the capillaries of the cortisone-treated and control skin areas amounting to more than ± 2 cm. mercury, the error of the method. The situation was markedly changed when stress was applied.

The human subjects did exhausting muscular work (swimming or gardening) or were exposed to ultra-violet light. On one subject the effect of delivering a strenuous class lecture was also studied. Dogs either ran in the treadmill or were irradiated by ultra-violet light or subjected to prolonged fasting. Following these various forms of stress the capillary resistance in skin area treated with cortisone was found to be significantly higher than in the control area in seven out of eight experiments in the human, and in eleven out of fourteen in the dogs. The differences showed wide individual variations amounting to 4–19 cm. mercury and were found to occur either within a few hours after stress or on the following day, and in most instances were demonstrable for several days. Two experiments, one in a human and one in a dog, exemplify in abbreviated form the phenomenon observed (Tables 1 and 2).

Table 2. Effect of a 25-day Fast (indicated between arrows) on Capillary Resistance and Capillary Sensitivity of an 18 kgm. Female Dog

For explanation see Table 1. Tests were made once daily between 1 and 2 p.m. During the period between the thirty-fifth and the forty-first days of the experiment no difference could be measured because capillary resistance in both areas was above the highest value measurable by the method (70 cm. mercury)

An attempt was then made to elucidate the mechanism by which capillaries are activated. There was no evidence that humoral factors play a part in this mechanism. Experiments on bilaterally sympathectomized dogs failed to demonstrate any capillary activation following stress. Activation was readily demonstrable in unilaterally sympathectomized dogs on the intact side but was entirely absent on the operated side. It appears, therefore, that activation, that is, increase in the sensitivity of the capillaries to corticosteroids, is intimately connected with the nervous system, specifically with the sympathetic nervous supply of the vessels.

The question whether or not other corticoid targets are activated by stress in a similar manner is open and does not appear to be as easily answerable as in the case of the capillaries. The present studies have in any event brought to light, through the specific example of the capillaries, a hitherto unknown ability of the organism to meet the demand induced by stress for increased corticosteroid activity in a manner other than by increased corticosteroid production.

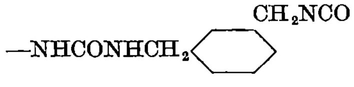
Preparation of an Electron-dense Antibody Conjugate

The fluorescent antibody conjugate technique recently developed by Coons[1] has already proved of great value in the study of biological problems. In this technique, a fluorescent substance is covalently linked to an antibody, and the antibody conjugate is allowed to react with cells or tissue containing its homologous antigen. The antigen is then detected and localized by observing the fluorescence in an optical microscope. For many reasons, it is desirable to extend this method to the sub-cellular level with the resolution attainable in the electron microscope. In order to achieve this purpose, however, it is necessary to confer sufficient electron density upon an antibody molecule, without inactivating it, to render it visible in the electron microscope.

We have prepared an electron-dense antibody conjugate by covalently coupling ferritin to the antibody. Ferritin is a crystalline protein of molecular weight 460,000 which is unique in that it contains as much as 23 per cent iron in ferric hydroxide–phosphate micelles[2]. Because of this electron density, individual ferritin molecules may readily be seen in the electron microscope[3]; they exhibit a characteristic micellar arrangement at the corners of a roughly square lattice.

The coupling of ferritin to the antibody was carried out as follows. To 5 ml. of a 1·6 per cent solution of crystalline horse spleen ferritin[2] in sodium borate buffer, *p*H 9·5, Γ/2 0·1 at 0° C., was added 0·10 ml. of *m*-xylylene di*iso*cyanate (the generous gift of the Carwin Co., North Haven, Connecticut). After ¾ hr. stirring at 0° C., the mixture was centrifuged, the supernatant solution was removed from the unreacted di*iso*cyanate, and was allowed to stand at 0° C. for an additional hour to allow any dissolved di*iso*cyanate to react. At this point, roughly half the free amino-groups of ferritin had reacted, presumably converted to



$$\text{—NHCONHCH}_2\text{—C}_6\text{H}_4\text{—CH}_2\text{NCO}$$

groups. This solution was then added to 5 ml. of a 1·6 per cent solution of rabbit γ-globulin (containing specific antibody), in the above-mentioned borate buffer containing, in addition, 1 *M* sodium chloride. After two days stirring at 6° C., the mixture was dialysed against 0·1 *M* ammonium carbonate to destroy any unreacted *iso*cyanate groups, and then was dialysed against phosphate buffer, *p*H 7·5, Γ/2 0·1. A small amount of precipitated protein was removed by centrifugation to give a clear stable solution.

To demonstrate that (*a*) the ferritin was conjugated to antibody, and (*b*) the ferritin–antibody conjugate was still capable of reacting specifically with its homologous antigen, the following experiments were performed. Two preparations of rabbit γ-globulin were available, one containing about 25 per cent anti-bovine serum albumin (BSA)Ab, the other about 20 per cent anti-bovine ribonuclease (RNase)Ab. Ferritin was treated with both by the procedure described above, giving preparations designated Fer-anti-BSA and Fer-anti-RNase, respectively. Two mixtures were then made, containing: (1) 2 mgm./ml. of Fer-anti-BSA and 1·5 mgm./ml. of unreacted anti-RNase γ-globulin; and (2) 3 mgm./ml. of Fer-anti-RNase and 1 mgm./ml. of unreacted anti-BSA γ-globulin, each in phosphate buffer, *p*H 7·5, Γ/2 0·1. 2-ml. portions of each mixture were then added to various dilutions of either RNase or BSA, and the precipitates formed after 24 hr. at 4° C. were washed and analysed for iron by the *o*-phenanthroline procedure, and for nitrogen by Nessler analysis.

Consider the results in the three upper sections (*A*, *B* and *C*) of Table 1. These clearly demonstrate that the presence of Fer-anti-BSA had no effect on the precipitation of RNase by anti-RNase, and therefore that the iron brought down in the RNase-(Fer-anti-RNase) precipitate must have been bound to specifically active antibody. Consistent with this conclusion is the essential independence of the iron/nitrogen ratio from the antigen/antibody ratio in the RNase-(Fer-anti-RNase) precipitates. Furthermore, if we assume that each Fer–Ab conjugate contains one ferritin and one antibody molecule, it follows from the iron/nitrogen ratios of 2·0 in our ferritin sample itself, and of 0·8 in the RNase-(Fer-anti-RNase) precipitates, that at least one-third of the antibody molecules were conjugated to ferritin. A larger fraction of antibody molecules could probably be coupled by using a larger mole ratio of ferritin to γ-globulin in the coupling reaction.

	0·031		0·078	0·052	0·67

In BSA-anti-BSA precipitations from solutions containing Fer-anti-RNase (section *E*, Table 1), some ferritin was brought down non-specifically. However, the iron/nitrogen ratio varied markedly with the antigen/antibody ratio in the precipitate. In particular, the iron/nitrogen ratio near the antigen–antibody equivalence zone was considerably smaller than the ratio in the specific BSA-(Fer-anti-BSA) precipitate (section *F*, Table 1). These results, therefore, while somewhat obscured by the non-specific precipitation, are consistent with the conclusions derived from the ribonuclease system.

The question of the specificity with which a Fer–Ab conjugate reacts with its homologous antigen is vital to the use of such conjugates in electron microscopic studies of cell and tissue sections. This question can only be answered at the electron microscopic level, however, and not by macroscopic antigen–antibody precipitation experiments. The specific behaviour of the RNase system, and the non-specific complications in the BSA system, are therefore not directly pertinent to this question.

Preliminary electron microscopic studies, in collaboration with Prof. William R. Adams, have indicated that in preparations of Fer–Ab conjugates, the characteristic micellar structure observed with ferritin itself is unaffected. These and further studies in progress, dealing with the application of the Fer–Ab conjugates to problems at the electron microscopic level, will be reported in detail elsewhere.

I gratefully acknowledge valuable discussions with Drs. Frank A. Pepe and Martin Saunders, and the competent technical assistance of Miss Julia McNeely.

Inhibition of Electron Transport and the Swelling of Isolated Mitochondria

THE swelling of isolated rat-liver mitochondria appears under certain conditions to be dependent on their respiration[1]. This view is based on the following observations. (*a*) Mitochondria 'aged' by storage for one day in 0·44 *M* sucrose at 0° C. did not swell in presence of phosphate or thyroxine unless an oxidizable substrate was added as well. (*b*) With succinate as the substrate, malonate inhibited the swelling and amytal did not; whereas with β-hydroxybutyrate, amytal inhibited and malonate did not. (Amytal prevents oxidation of substrates with diphosphopyridine nucleotide-linked dehydrogenases, but has no effect on that of succinate[2].) (*c*) Cyanide inhibited swelling induced by phosphate, but not when electron transport was restored by addition of ferricyanide as terminal acceptor[3]. (*d*) Antimycin *A* inhibited swelling in presence of phosphate with various substrates[1,3]. The effects of amytal and antimycin on swelling have now been investigated further.

The experimental conditions have been described previously[1]. Antimycin in concentrations known to inhibit many mitochondrial oxidations[4] (3–50 mμgm./ml.) had only a small effect on the swelling induced by 10 m*M* phosphate or 30 μ*M* L-thyroxine with fresh mitochondria. In contrast, with aged mitochondria in the presence of 1 m*M* D-β-hydroxybutyrate, 5–8 mμgm. antimycin/ml. completely arrested the swelling induced by phosphate or thyroxine. However, when the β-hydroxybutyrate was replaced by L-glutamate, L-malate, L-proline or succinate (all 1 m*M*) the inhibition of phosphate-induced swelling was much less, and was only partial even with 50 mμgm./ml. (Fig. 1). A selective effect was observed with amytal as well. Unlike antimycin, amytal[2] (1·8 m*M*) completely arrested the swelling of fresh mitochondria induced by phosphate or thyroxine. With aged mitochondria, however, amytal resembled antimycin (Fig. 1), in that when β-hydroxybutyrate was present, a given inhibition was produced by a lower concentration of the barbiturate than that which was required with glutamate (Fig. 2).

Fresh mitochondria have been shown to contain substrates, for example, citrate[5] and precursors of glutamate[6], and to have a significant endogenous respiration[7]. It is therefore reasonable to suppose that the swelling of fresh particles is supported by oxidation of intrinsic material. We have seen that antimycin in the concentrations tested had little effect on the swelling of fresh mitochondria in absence of added substrate, whereas it was profoundly inhibitory with aged particles in presence of β-hydroxybutyrate. If this substrate were added to fresh mitochondria, it might be expected that antimycin would remain ineffective, swelling still being supported by the endogenous respiration, which is not sensitive to antimycin. Surprisingly, however, 5–50 mμgm. of antimycin/ml. strongly inhibited the phosphate-induced swelling of fresh mitochondria in the presence of β-hydroxybutyrate (Fig. 3). This suppression of the phosphate swelling was not obtained when β-hydroxybutyrate was replaced by malate; glutamate gave a slight effect. With ferricyanide present as terminal electron acceptor, antimycin had a similar action, that is, the phosphate-induced swelling, which was little affected by the antibiotic, was almost completely inhibited in the presence of β-hydroxybutyrate[3].

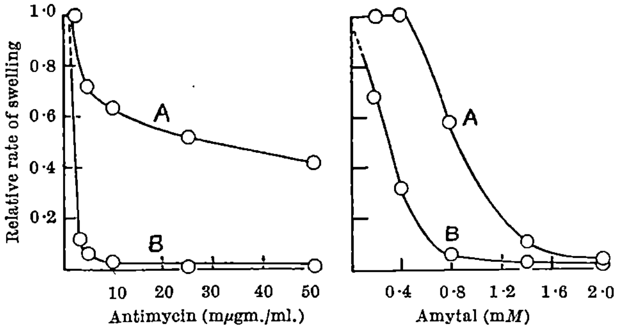

Fig. 1 Fig. 2

Figs. 1 and 2. Effects of antimycin *A* (Fig. 1) or amytal (Fig. 2) on the swelling induced by phosphate of aged mitochondria with 1 m*M* D-β-hydroxybutyrate or L-glutamate as substrates. The ordinates represent the steady rate of swelling in the presence of inhibitor relative to the maximal rate in an uninhibited control. Each cell contained 0·3 *M* sucrose, 25 m*M* *tris* chloride buffer, *p*H 7·5, and 10 m*M* phosphate. 20° C. Curve *A*, L-glutamate; curve *B*, β-hydroxybutyrate

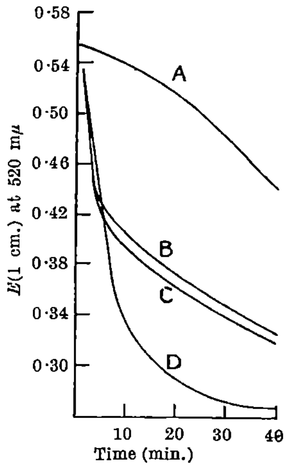

Fig. 3. Effects of antimycin *A* (20 mμgm./ml.) on swelling induced by phosphate of fresh mitochondria with and without D-β-hydroxybutyrate. Experimental conditions as for Figs. 1 and 2. Curve *A*, phosphate, β-hydroxybutyrate + antimycin; curve *B*, phosphate + antimycin; curve *C*, phosphate; curve *D*, phosphate + β-hydroxybutyrate

The action of the combination of β-hydroxybutyrate and antimycin was not restricted to fresh mitochondria, for with aged particles in which swelling due to phosphate was supported by glutamate, the further addition of DL-β-hydroxybutyrate together with antimycin completely checked the increase in volume, whereas antimycin alone caused an inhibition of only about 50 per cent.

In some respects oligomycin, which inhibits the phosphorylation system and thereby considerably reduces respiration in coupled systems[8], has an action on mitochondrial swelling like that of antimycin. Oligomycin (0·4 μgm./ml.) had a very small effect on the phosphate-induced swelling of fresh mitochondria, but when DL-β-hydroxybutyrate was present as well, almost complete inhibition resulted. In contrast to that of antimycin, this effect was counteracted by 2 : 4-dinitrophenol[3].

To summarize, it has been shown that antimycin and amytal caused an inhibition of mitochondrial swelling which depended on the substrate present; maximal sensitivity to these agents was observed when β-hydroxybutyrate was present, and minimal effects with no added substrate, that is, when the mitochondria were presumably dependent on their endogenous respiration. Other substrates showed behaviour between these extremes.

The protective action of β-hydroxybutyrate with fresh mitochondria in presence of antimycin or oligomycin is not readily explained in the light of our present knowledge. It seems to indicate an inhibition of endogenous respiration by β-hydroxybutyrate even when the oxidation of the latter is suppressed. Experiments are in progress, both with the oxygen electrode and with a new method for measuring ferricyanide reduction[3], to determine whether interaction of this kind takes place. If none is found, an explanation of our findings must be sought in terms of the respiration – swelling transducer mechanism.

We wish to thank Dr. B. C. Pressman for a generous gift of oligomycin and Mr. Colin Taylor for expert technical assistance.

Methanol-soluble Carbohydrate Complexes

We have found that carbohydrates of low molecular weight are generally highly soluble in concentrated solutions of anhydrous calcium chloride in cold absolute methanol. After some time, crystalline methanol-solvated complexes of calcium chloride and carbohydrate are deposited. Such solutions and methanol-solvated complexes have not been reported before.

Lactose is the carbohydrate we have studied most thoroughly. A highly concentrated solution is prepared, for example, by mixing at 40° C. lactose, calcium chloride and methanol in a molar ratio such as 1 : 3 : 24. Paper chromatographic analysis of the aged solution shows that more than 97 per cent of the lactose remains unchanged and that a minor constituent has formed to the extent of less than 3 per cent. The specific rotations have been measured in water ; $[\alpha]_i$ refers to the value extrapolated to the instant of mixing with water, and $[\alpha]_f$ to the later equilibrium value ; the rotational effects of the calcium chloride and methanol are negligible under the conditions of measurement. That the α-form of lactose exists in higher proportion in methanolic calcium chloride solution than in water is shown by the ratio of $[\alpha]_i$ to $[\alpha]_f$, which equals 1·30. However, since $[\alpha]_f$ of the lactose in the methanolic solution is 43·5, while $[\alpha]_f$ of the lactose used as starting material is 55·3, the minor constituent which was found in the chromatographic analysis must have a very low or negative rotation.

From the highly concentrated methanolic solution, heavy crystallization occurs after months, or, when it is seeded and shaken, after several days or weeks. The crystals are separated by prolonged centrifugal filtration in a closed system, since they cannot be washed without change in composition. The crystals are first dried at 60° C. to evaporate the methanol, and then at 105° C. If heated first at 105° C., they decompose. Analysis shows that the crystals consist of 1 mole of lactose, 1 mole of calcium chloride, and 4 moles of methanol. Polarimetry shows that nearly all the lactose is present in its β-form.

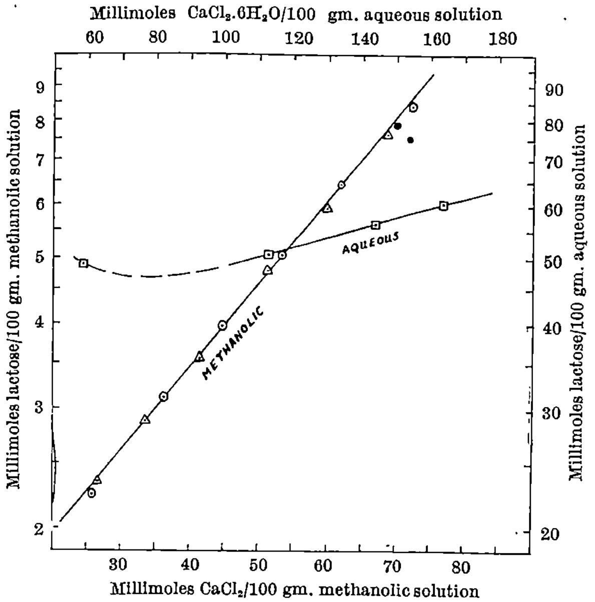

Fig. 1. △, ⊙, Solubility of lactose in methanolic calcium chloride, from two similar sets of experiments ; ⊡, solubility of lactose in aqueous calcium chloride, according to Herrington (ref. 1).

The dilution of the concentrated lactose solution with methanol causes lactose to crystallize. The ratio of $[\alpha]_i$ to $[\alpha]_f$ for these crystals equals 1·28 ; the final rotation $[\alpha]_f$ is 54·7. While this ratio is the same as exists in solution, these crystals do not contain the minor constituent which affects the final rotation in solution. Within the range investigated, the logarithm of the solubility of this crystallized lactose in methanol is a linear function of the calcium chloride concentration (Fig. 1). Herrington[1] determined the solubilities of lactose in aqueous calcium chloride solutions. If one plots (Fig. 1) the results of his four tests in which lactose was the solid phase, the logarithm of the lactose concentration turns out to be another straight line for the highest of three points ; the lowest point is off the line.

When about 6 moles of water are added to the highly viscous methanolic lactose solution for each mole of dissolved calcium chloride, the maximum amount of a complex consisting of (lactose. $CaCl_2$. $7H_2O$) gradually crystallizes over a period of a few days. Adding either more water or less lowers the yield. The lactose in these crystals is the α-form. These crystals are identical with those deposited from water according to Herrington's procedure[1].

Solubilities of several carbohydrates were determined in a qualitative way by the mixing of the carbohydrate with calcium chloride and methanol in a molar ratio of 1 : 3 : 24 at 28°. In general, monoses, bioses and trioses, and their simple derivatives were found soluble ; only the higher polysaccharides (for example, dextrin) are insoluble. The following are soluble : the sugars D-glucose, D-galactose, L-sorbose, D-fructose, sucrose, maltose, melezitose and raffinose, and the sugar derivatives α-methyl-D-glucoside, D-gluconolactone, sorbitol, lactobionolactone, and lactositol.

Some of the monoses, for example, glucose and fructose, crystallize very rapidly as methanol-solvated calcium chloride complexes. The fructose solution is of special interest in that soon after it begins to crystallize it becomes a translucent homogeneous rigid gel which fills the entire volume of the solution.

Methanolic calcium chloride might serve as a solvent for sugar reactions and for fractionating sugar mixtures by extraction or crystallization.

A fuller report is to be published elsewhere.

Effects of Vanadium upon Liver Coenzyme *A* in Rats

THE addition of vanadium to liver sections of normal animals can prevent the synthesis of cholesterol from both mevalonic acid and acetate[1]. Diets containing vanadyl sulphate do not, however, alter the cholesterol-levels in the serum or liver after being administered for six weeks to rabbits fed on high-cholesterol diets, though they considerably reduce the cholesterol concentration in the aorta and appreciably lower the capacity of the liver to synthesize cholesterol[1,2].

On these grounds, a study was carried out aimed at assessing the effects of vanadium upon the liver coenzyme *A*—for it is an established fact that the synthesis of cholesterol from acetate is promoted by the activation of acetate by coenzyme *A*.

The first experiments were devoted to investigating the effects of vanadium upon the serum and liver cholesterol contents in (1) normal rats, (2) rats that had been kept on a high-cholesterol diet and (3) rats that had been administered intravenous injections of 'Triton' *WR* 1339 (arylalchylic phenol polyether) a surface-active substance that can enhance the cholesterol-synthesizing capacity of the liver[3]. Other experiments were devoted to assessing the effects of vanadium upon the coenzyme *A* of the liver.

The test were performed on white rats of our breeding, average weight 90–120 gm., fed *ad libitum* for 7 days before the experiment on a standard diet (diet *A*) of 21 per cent casein, 7 per cent olive oil, 4 per cent salt mixture IV, 5 per cent vitaminized lactose and 63 per cent sugar.

The hyperlipæmia from 'Triton' *WR* 1339 was determined by injecting the surface-active substance intravenously. Vanadium, in the form of an aqueous solution of sodium metavanadate ($NaVO_3.H_2O$), was simultaneously administered by intraperitoneal injection. The animals were killed by decapitation 18 hr. after the injection, and their sera and livers were analysed for total cholesterol by the Sperry–Webb[4] and Abell[5] methods, respectively.

Table 1. EFFECTS OF VANADIUM UPON THE CHOLESTEROL CONTENTS IN THE LIVER AND SERUM OF RATS UNDER VARYING EXPERIMENTAL CONDITIONS (AVERAGE VALUES ± S.E.)

No. of animals	Diet	Triton (mgm./kgm.)	Vanadium	Total cholesterol (mgm./100 gm. or 100 ml.) Serum	Liver
10	*A*	—	—	71·4 ± 4·33	204·5 ± 9·78
12	*A*	—	5 mgm./kgm. i.p.*	67·6 ± 3·48	182·9 ± 7·06
12	*A*	200	—	264·9 ±12·04	1,083·8 ±38·75
13	*A*	200	5 mgm./kgm. i.p.	197·2 ±11·81	741·8 ±21·14
15	*B*	—		80·6 ± 5·27	725·3 ±24·33
15	*B*	—	0·01 per cent in diet	74·9 ± 6·10	640·5 ±19·84
15	*B*	—	0·05 per cent in diet	76·6 ± 6·32	597·4 ±15·45

* i.p., intraperitoneal.

Table 2. EFFECTS OF VANADIUM ON THE COENZYME *A* IN THE LIVER OF NORMAL RATS (AVERAGE VALUE ± S.E.)

No. of animals	Vanadium	Days of treatment	Coenzyme *A* U./gm. liver	U./100 mgm. protein
12	—	—	138·1 ±3·75	103·5 ±3·29
15	5 mgm./kgm. i.p.*	1	135·7 ±3·49	94·9 ±3·12
15	5 mgm./kgm. i.p.	6	101·4 ±2·64	81·1 ±2·40
15	10 mgm./kgm. i.p.	1	83·0 ±2·12	68·5 ±2·18
12	0·01 per cent in diet	7	124·5 ±3·60	98·3 ±2·78
12	0·01 per cent in diet	14	97·6 ±2·35	84·7 ±2·11
12	0·05 per cent in diet	7	91·2 ±2·07	76·0 ±2·42
12	0·05 per cent in diet	14	68·5 ±2·15	59·4 ±1·29

* i.p., intraperitoneal.

The results are shown in Table 1, together with those concerning the effects of vanadium upon the cholesterol content of the serum and liver of normal subjects. In the same table the results obtained by administering vanadium for 7 days with a diet *A* containing an extra 1 per cent cholesterol (diet *B*) are also tabulated.

The effects on the coenzyme contents of the liver of vanadium administration, either parenterally or incorporated in our diet *A*, are tabulated in Table 2. The coenzyme content was determined by the Kaplan and Lipmann method[6] on two-thirds of each liver, the remainder being used for protein determination by the Folin method as amended by Lowry[7].

From Table 1 it can be seen that no significant changes occur in the cholesterol-levels in the liver and serum of normal animals 18 hr. after the vanadium injection. Now, since the same vanadium dose appears to lower to a fair extent the cholesterol-levels in the animals treated with 'Triton' the assumption that the metal exerts its effect only when cholesterol synthesis has been abnormally enhanced appears to be justified.

In animals kept on a high-cholesterol diet, the amount of cholesterol in the liver is reduced, though only to a moderate extent, even when only 0·01 per cent vanadium is added to the food. (The effect remains more or less unchanged as the vanadium percentage is increased.)

The effect of vanadium injected intraperitoneally on the coenzyme *A* of the liver becomes evident 24 hr. after a single administration of 10 mgm./kgm., or 6 days after a 5 mgm./kgm. daily dose.

When administered in the diet at a concentration of 0·01 per cent over 7 days, the metal does not seem to exert any significant action, the effects becoming apparent after a 14-day treatment. At a concentration of 0·05 per cent in the diet, a reduction in the coenzyme *A* of the liver is observable after 7 days; after a 14-day treatment it becomes considerable and may be as much as 40 per cent less than normal.

Our investigations have not yet detected the mechanism of the inhibiting action of vanadium upon the coenzyme *A*. Other workers[8] have suggested that the metabolism of sulphurated amino-acids would be affected by vanadium. If so, considering the important role of the thiolic cell components in biosynthesis of the coenzyme, a shortage might be postulated of the sulphydryl groups, notably cysteine, that are needed for the formation of pantotheine.

Separation of Mono-*n*-butyl Phosphate and Di-*n*-butyl Phosphate by means of Ion Exclusion

Many different methods have been applied by several authors to the separation of mono- and di-*n*-butyl phosphate. Kumler and Eiler[1], who were interested in obtaining pure samples for the determination of their dissociation constants, used fractional precipitation of barium salts. Extraction by organic solvents (*n*-amylic alcohol or dibutylic ether) was applied with a good yield by Stewart and Crandall[2]; di-*n*-butyl phosphate is preferentially extracted into the organic phase. With the aim of obtaining mono- and di-*n*-butyl phosphate labelled with phosphorus-32, after the isotopic transfer of phosphorus-32 from $H_3{}^{32}PO_4$ to the esters, the exchange resin 'Dowex 2 *X*–8', 100–200 mesh, chloride form, was used by Higgins and Baldwin[3] to separate the three components from each other. Thus the mixture at *p*H 9 was fixed at the top of the resin bed; *ortho*-phosphoric acid, mono- and di-*n*-butyl phosphate were consecutively obtained by eluting with 0·05 *M* hydrochloric acid and with 0·5 *M* potassium chloride.

Separations of the same type were also carried out in our laboratory with satisfactory results, by using 'Amberlite *IRA* 400', carbonate form, and 0·1 *M* sodium carbonate and 0·1 *M* sodium chloride as selective eluants.

To investigate another way of separation, some ion exclusion experiments were carried out by us. This method needs no regeneration of the resin, which acts with a different mechanism from that of common ionic exchange. Many factors are reported to determine the limitations of ion exclusion[4]; among them are: rate of flow of solution through the column; volume of feed and concentration ratio of the two components; operating temperature; size of resin particles and percentage of cross-linkage; degree of dissociation of compounds to be separated. In principle, separation through ion exclusion is effective when compounds involved possess different degrees of dissociation, because one component acts as an 'ionic substance' in respect to the other 'non-ionic'.

Even though mono- and di-*n*-butyl phosphate have nearly the same dissociation constants[1] (for mono-*n*-butyl phosphate $K' = 1{\cdot}29 \times 10^{-2}$, $K'' = 1{\cdot}40 \times 10^{-7}$ and for di-*n*-butyl phosphate $K = 1{\cdot}90 \times 10^{-2}$) a fairly good separation was obtained by operating in the conditions reported below. A bed of 50 c.c. of 'Dowex 50 *X*–8', 50–100 mesh, hydrogen form, having a cross-section of 1·1 cm.^{2}, was fed with 9 ml. of a solution containing 0·071 m.moles/ml. of mono-*n*-butyl phosphate and 0·037 m.moles/ml. of di-*n*-butyl phosphate at a flow-rate of 6·25 ml./hr. cm.^{2}. While eluting at room temperature (18° C.), with distilled water at the same rate of flow, fractions of 2·2 ml. were automatically collected. Results are shown in Fig. 1, where mono-*n*-butyl phosphate is shown appearing after 18 ml. of effluent and di-*n*-butyl phosphate after 38 ml., as was expected on a theoretical base. Furthermore, it should be pointed out that mono-*n*-butyl phosphate, in spite of its slightly lower dissociation constant, is eluted first. The yield of separation is 95·5 per cent in pure mono- and 89 per cent in pure di-*n*-butyl phosphate, since in one fraction alone the two components were both present. Rate of flow can be raised to 9 ml./hr. cm.^{2} and feed concentration varied at about ±10 per cent without influencing the separation yield, which is lowered only when the amount of resin is reduced by 20 per cent.

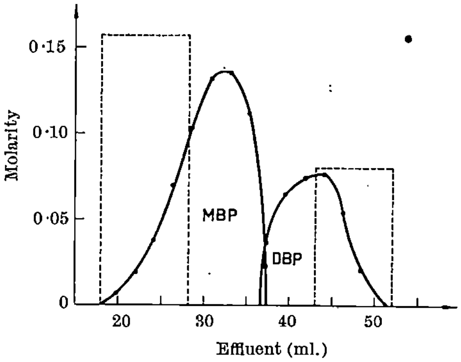

Fig. 1. Elution curves for mono- and di-*n*-butyl phosphate. Dashed lines indicate the theoretical shape of the separation

To prepare significant amounts of pure compounds, seven semi-continuous cycles were carried out, on 650 c.c. of resin, 5·2 cm.^{2} cross-section. Each cycle employed 100 ml. of feed solution containing 0·061 m.moles/ml. of mono-*n*-butyl phosphate and 0·028 m.moles/ml. of di-*n*-butyl phosphate, at a rate of flow of 9 ml./hr. cm.^{2}.

All the experiments described here were performed on solutions of mono- and di-*n*-butyl phosphate obtained synthetically from phosphorus pentoxide and butanol, and brought to suitable concentrations by dilution with water.

Analyses of fractions were carried out by potentiometric titration with 0·1 or 0·01 *N* sodium hydroxide; in some cases a purity control by paper chromatography was effected[5].

Structure of Dihydrodiphosphopyridine Nucleotide

WEBER[1] has recently reported on the intramolecular transfer of excitation energy in dihydrodiphosphopyridine nucleotide. In addition to the strong band having its maximum at 340 mμ, the excitation spectrum of the 462 mμ fluorescence also shows a maximum at 260 mμ, a region where the absorption is due to the purine part of the molecule.

Kaplan *et al.*[2] have identified an isomer of diphosphopyridine nucleotide which comprises 10–15 per cent of a highly purified commercial preparation of diphosphopyridine nucleotide. The isomer was characterized by optical rotation studies as the α-glycoside of nicotinamide riboside as distinct from the biologically active β-isomer of diphosphopyridine nucleotide. This assignment of configuration about the C_1 of ribose was substantiated by the synthetic preparation of nicotinamide mononucleotide[3] to give a mixture of the β- and α-anomers in a 4 : 1 ratio.

The α-isomer of diphosphopyridine nucleotide was reduced chemically with sodium dithionite[4] and the product was examined spectrofluorometrically. Unlike the β-isomer, the excitation spectrum of the 462 mμ fluorescence of α-dihydrodiphosphopyridine nucleotide shows a strong band only when activated at 340 mμ and not when irradiated at 260 mμ, indicating that excitation energy transfer is not as efficient with the α-isomer as was observed with the β-isomer. The 462 mμ fluorescence resulting from 260 mμ and 340 mμ excitation of α- and β-dihydrodiphosphopyridine nucleotide is shown in Fig. 1.

Further evidence for the differences in interaction in the α- and β-isomers of dihydrodiphosphopyridine nucleotide may be found in their spectrophotometric behaviour in water and propylene glycol. Weber[1] reported that the ratio E_{260}/E_{340} is 2·85 for the intact β-isomer of dihydrophosphopyridine nucleotide, whereas this ratio becomes 3·4 in propylene glycol. A similar examination of the reduced α-isomer reveals that the E_{260}/E_{340} ratio is the same in water as in the propylene glycol.

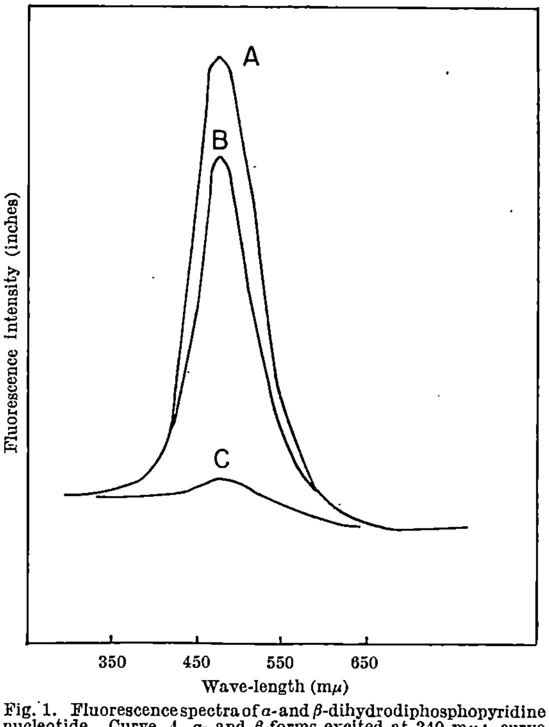

Fig. 1. Fluorescence spectra of α- and β-dihydrodiphosphopyridine nucleotide. Curve *A*, α- and β-forms excited at 340 mμ; curve *B*, β-form excited at 260 mμ; curve *C*, α-form excited at 260 mμ. These values are relative since the intensities of the exciting light have not been determined

Studies similar to those described for the α-isomer of dihydrodiphosphopyridine nucleotide have been carried out with deamino-dihydrodiphosphopyridine nucleotide (the hypoxanthine analogue[5]) and with the 3-acetylpyridine analogue[6]. The latter analogue clearly showed the transfer of excitation energy since excitation at 260 mμ gives a 478-mμ fluorescence[7] which is also elicited by excitation at 365 mμ. The absorption spectrum of this analogue behaved much like β-dihydrodiphosphopyridine nucleotide in water and propylene glycol. The deamino-dihydrodiphosphopyridine nucleotide, however, did not show properties of energy transfer, since excitation of the purine ring did not result in fluorescence of the dihydropyridine nucleus.

In accordance with the postulate by Weber[1] that the adenine and the dihydropyridine rings form a complex in β-dihydrodiphosphopyridine nucleotide, it appears that such complex formation cannot occur in the α-isomer.

Further studies on the structural conformation of diphosphopyridine nucleotide and dihydrodiphosphopyridine nucleotide are being examined in this laboratory through the use of pyridine coenzyme analogues.

A Possible Negative Feedback Phenomenon controlling Formation of Alkaline Phosphomonoesterase in *Escherichia coli*

WE have already reported[1] that in a phosphate-deficient medium the amount of ribonucleic acid in *E. coli* decreased remarkably, while there was an appreciable increase of deoxyribonucleic acid, protein and viable cell numbers. At the same time we also studied activities of some enzymes presumed to be related to the degradation of ribonucleic acid, for example, ribonuclease phosphodiesterase and phosphomonoesterase, and found a marked increase in that of phosphomonoesterase. This communication is concerned with this formation of phosphomonoesterase in *E. coli*.

The strain used was *E. coli B* and the medium contained per litre: 3·0 gm. NaCl, 0·25 gm.

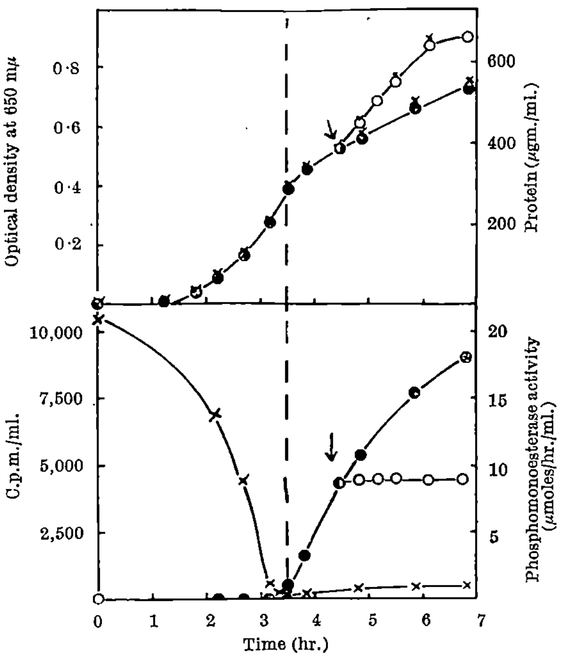

Fig. 1. Relation between the formation of phosphomonoesterase and phosphate content in the medium. Cells were suspended in a medium containing phosphorus-32 at 10 μgm. phosphorus/ml. and incubated at 37° C. with shaking. At the time indicated aliquot samples were taken to assay phosphomonoesterase activity and protein content (see text). At the time indicated by arrows, the culture was divided into two portions, to one of which (○—○) was added phosphate (100 μgm./ml.) and to the other (●—●) water. Radioactivity of the medium was obtained from that of the supernatant fraction after centrifugation (10,000*g*; 5 min.). The broken line indicates the time when the phosphate in the medium was exhausted. ●, ○, Optical density; ×, protein concentration

$MgSO_4.7H_2O$, 0·01 gm. $CaCl_2$, 2·0 gm. sodium lactate, 10·0 gm. Difco 'Bactopeptone' and 12 gm. *tris*-(hydroxymethyl)-aminomethane. The *p*H was 7·4. This medium contained 16 μgm. phosphorus/ml. Phosphomonoesterase activity was measured by the method of Bessey *et al.*[2], using *p*-nitrophenyl phosphate as the substrate, glycine–sodium hydroxide buffer (*p*H 9·5) and magnesium sulphate. Activity of phosphomonoesterase was expressed as μmoles of *p*-nitrophenyl phosphate hydrolysed/hr./ml. of toluene-lysed cell suspension[3]. Protein was estimated by the method of Lowry *et al.*[4] using bovine serum albumin as standard.

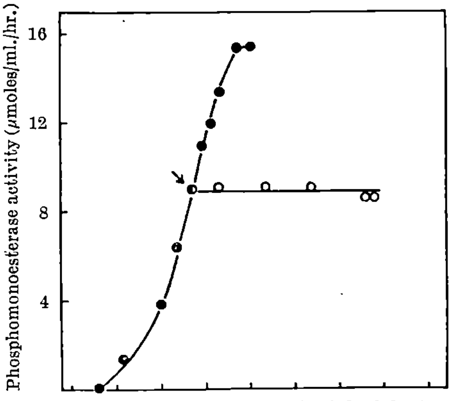

Fig. 2. Relation between the activity of phosphomonoesterase and optical density of the culture. Experimental conditions and key as in Fig. 1

As illustrated in Fig. 1, cells began to form phosphomonoesterase when the phosphate in the medium was exhausted. Thereafter, a linear increase of activity was observed for 2–3 hr. and the amount of cell protein/ml. increased linearly, although at a low rate. Fig. 2 shows the relation between the increase of optical density and that of the phosphomonoesterase activity. As shown in Fig. 2 this increment of protein was directly proportional to that of phosphomonoesterase activity, except in the early and in the final phases of the phosphate-deficient stage. The formation of phosphomonoesterase was stopped immediately by the addition of phosphate to the medium (final concentration: 100 μgm. phosphorus/ml.), though the amount of protein increased at a high rate (Figs. 1 and 2). The appearance of phosphomonoesterase activity was not observed in the phosphate-rich medium. Apparently phosphate inhibits the action of phosphomonoesterase.

In view of the above results, it seems to us that the formation of phosphomonoesterase is an important factor in the regulation system of the phosphate economy in *E. coli*. A negative feedback mechanism[5] is possible, with phosphate as a repressor, although the activation of phosphomonoesterase cannot be ruled out. Further details will be published elsewhere.

RADIOBIOLOGY

Effect of High Oxygen Pressure on the Protective Action of Cystamine and 5-Hydroxytryptamine in Irradiated Rats

Both the oxidized disulphide, cystamine (—S—S—) and its corresponding sulphydryl amine, cysteamine (—SH) are excellent radioprotective agents *in vivo*[1]. If rats, protected by the latter reduced substance, respire pure oxygen under pressure (4–5 atmospheres absolute) at the time of irradiation, the protective action is completely reversed[2,3] and this result also applies to cysteine. Our own findings have shown that this reversal also applies to the pharmacologically active amines, histamine and adrenalin, and largely to 5-hydroxytryptamine (*vide infra*). The lessening of the radioprotective action of these reducing agents by an increased oxygen pressure in tissue fluids may be due to the inactivation of additional —SH and reducing groups supplied to the body, or due to an increase in physical solution and diffusion of oxygen so provided, in overcoming the anoxæmia caused by either decreased oxygen-carrying capacity of hæmoglobin (for example, with *para*-aminopropiophenone[3]), or by smooth muscle constric-

Table 1. Fffect of Respired Oxygen Pressure on the Protective Actions of Cystamine and 5-Hydroxytryptamine against Acute Radiation* Lethality in Rats† and Effect of Added Pretreatment with Sodium Cyanide

Experiment	Respired gas (pressure in atmospheres absolute)	Survivors at 30 days (per cent)	Mean survival over 30 days (± *S.D.*)

Experiment 4. Rats pretreated with sodium cyanide§ (2 mgm.) and 5-hydroxytryptamine‡ (2 mgm.).

* All animals received 1,000 r. X-rays whole-body irradiation.

† Rats of Canberra black stock weighing 150–190 gm., of equal sexes.

‡ Cystamine or 5-hydroxytryptamine administered as intraperitoneal injection 5 min. preceding irradiation.

§ Sodium cyanide administered intraperitoneally 5 min. prior to injection of protective agent (cystamine or 5-hydroxytryptamine).

tion in bronchioles or arterioles resulting from pharmacological action (for example, 5-hydroxytryptamine[4]). However, the protective disulphide, cystamine (—S—S—), is reduced to cysteamine (—SH), *in vivo*[5] and *in vitro*[6], and increased oxygen pressure *in vivo* may be expected to lessen its protective action, if the latter depends on the reduction of cystamine in tissues, to produce available —SH groups, or promote pharmacological activity, both of which tend to result in intracellular anoxia.

Our studies of the effect of respired oxygen tension on the protective action of cystamine and 5-hydroxytryptamine in rats subjected to acute lethal whole-body irradiation show that an increase in respired oxygen pressure to 4 and 5 atmospheres absolute pressure almost completely reverses the protective action of 5-hydroxytryptamine but fails to cause significant reduction in the protective action of cystamine. An example of the experimental results is given in Table 1. It is seen that pretreatment with sodium cyanide, itself a reducing substance but not protective in rats[7,8], results in a substantial reduction in the protective action of cystamine (and 5-hydroxytryptamine) if combined with increased oxygen pressure. In other experiments in which the dose of cystamine was reduced to 4, 8 and 12 mgm./rat respectively, raised oxygen pressures (4 atmospheres absolute) also failed to decrease the lesser protective action resulting and, indeed, tended to enhance the protective action to levels corresponding to a higher dosage of cystamine.

The results indicate that the protective action of cystamine (—S—S—) does not result entirely from the formation *in vivo* of cysteamine (—SH), although the enhancement of protective action at lower dose levels may support the hypothesis of Pihl and Eldjarn[9] that the degree of protective action is correlated with the ability to form mixed disulphides. That protective action for the disulphide depends on its histamine-liberating qualities[10] is not supported by our findings with histamine protection and its reversal by oxygen respired at 2 atmospheres absolute[8]. Again, the effect of combined cyanide pretreatment and oxygen pressure (Table 1) fails to support the theory of free-radical competition as applied to radioprotection *in vivo* of either cystamine or reducing substances, and a decrease of intracellular oxygen pressures (delayed by pretreatment with respiratory enzyme poisons) seems to be at least an important contributing factor. If the transfer of oxygen across cellular membranes involves active transport mechanisms, as distinct from simple physical diffusion, it may be easier to interpret chemical protection in terms of an 'oxygen effect'. These studies will be reported in full elsewhere.

Effect of X-Rays on the Cell

It is well known that the inhibition of the synthesis of nucleic acid plays a very important part in the chain of the post-irradiation changes and particularly in the blocking of mitosis. But this hypothesis does not explain the great susceptibility of mitosis to comparatively small doses of irradiation[1]. The generalization relating sensitivity to mitotic activity fails when applied to lymphocytes. Other important biochemical processes in the cell, as, for example, the oxidative phosphorylation, are also sensitive to irradiation[2]. It cannot be excluded that other cellular functions are also impaired by X-rays.

We were able to demonstrate that, as yet, unknown changes[3] occur in tissue after small doses of irradiation. We incubated the tissue homogenate at 38° C. and found that coagulation occurred in a homogenate prepared from the organ of the irradiated rat, whereas coagulation did not occur in a similar homogenate prepared from tissue from a non-irradiated animal. We found this effect with the spleen, and also with 'radioresistant' liver tissue.

The coagulation phenomena may best be followed with the aid of turbidometric measurements. The present communication reports some properties of liver homogenates from irradiated and non-irradiated rats, studied by this method and by *p*H measurements.

The animals generally used in our experiments were Wistar albino rats of both sexes. We used a 'Super Sanax' X-ray apparatus operated at 180 kV. and 15 m.amp. with 1-mm. aluminium and 0·5-mm. copper filters, focus distance 53 cm., dose-rate 40 r./min. Animals were killed by decapitation 30 min.

after irradiation. The liver was removed after perfusion *in situ* with cold physiological saline and gently homogenized in distilled water (1 gm. in 10 ml.). We used a chilled loose Potter–Elvehjem glass homogenizer (about 20 up-and-down strokes of the pestle, driven at 1,500 rev./min.). Colorimeter tubes were filled with the whole homogenate, consisting chiefly of disrupted and partly of whole cells (after filtration through mill cloth) and the increase of optical density during incubation was measured against water using a green-yellow filter. In some experiments we measured the *p*H of the homogenate during the incubation (ionoscope apparatus) with antimony and calomel electrodes at 22° C.

We found that the coagulation of the homogenate from irradiated rats takes place more quickly in comparison with the coagulation of the control. It is interesting that it is possible to prove by this method the effect of a dose of 10 r. The speed of coagulation depends on the dose of irradiation (Table 1).

Table 1

Irradiation dose	Time of incubation at 38° C. required to reduce light transmission of homogenate by 50 per cent (average for 3 rats)
500 r.	265 min.
100 r.	295 min.
10 r.	375 min.
Control	425 min.

Raising the temperature of incubation accelerates the coagulation of the liver homogenate from the irradiated animal as well as that of the control. The *p*H in liver homogenate from irradiated animals falls more rapidly than that from controls (Fig. 1).

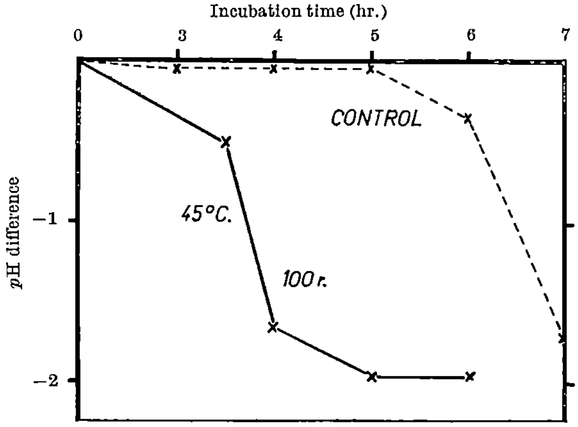

Fig 1. Drop in the *p*H of liver homogenate from irradiated and non-irradiated rats

We studied similar phenomena on spleen homogenate. It coagulates faster than liver homogenate, however, so that it is more difficult to demonstrate the influence of small doses of irradiation in that case.

PATHOLOGY

Prevention of Adaptive Formation of Tryptophan Peroxidase by a Carcinogenic Azo Dye

The carcinogenic azodye 3′-methyl,4-dimethyl aminoazobenzene induces gross tumours in livers of rats fed a basal diet poor in riboflavin[1]. The whole process, in Sprague–Dawley rats, takes approximately 200 days. Structural damage to liver tissue may be detected histologically during the first weeks of carcinogen feeding[2]. Intracellular changes, manifested by the gradual depletion of mitochondria and ergastoplasm, which result in respiratory damage to the cell, can be detected by differential centrifugation weeks and even months before onset of malignancy[3]; yet all these changes are long-range effects. Even though the continual administration of this carcinogen brings about respiratory damage to the cell, the carcinogen is not a respiratory inhibitor[4,5]. It can be shown that the specific respiratory activity (activity per mgm. protein nitrogen) with sodium pyruvate as substrate remains normal for mitochondria during feeding with this carcinogen although the tissue is full of protein-bound azodye[5]. In short, the immediate chemical effect of this carcinogen, apart from its binding to one or more proteins not yet functionally characterized[6], is still obscure.

Assuming that the depletion of cytoplasmic structures may be due to the interference of the carcinogen with some phase of the mechanism of protein synthesis, we decided to study its effect on adaptive enzyme formation. It is known that tryptophan peroxidase is an adaptive enzyme formed in mammalian livers in increased amounts following the injection of L-tryptophan[7]. The enzyme is synthesized *de novo* by the liver cell from its constituent amino-acids[8]. It was reported recently[9] that there exists in the hepatoma a block in the pathway of tryptophan metabolism via kynurenin, indicating the absence of tryptophan peroxidase. There seem to be no results, however, in the literature on the level of this enzyme and its adaptive synthesis in the precancerous liver. For these reasons we investigated the induction of tryptophan peroxidase in livers of Sprague–Dawley rats (two months old at the beginning of the experiment) fed for various lengths of time on a basal diet containing 3′-methyl,4-dimethyl aminoazobenzene (twice recrystallized, 600 mgm./kgm. of food) as compared with controls on a basal diet without the carcinogen.

L-Tryptophan (78 mgm. in 10 ml.) was injected intraperitoneally to half the animals; the other half remained uninjected. 6 hr. after injection all animals were killed. The liver tissue was homogenized in isotonic neutral potassium chloride. Tryptophan peroxidase was assayed by the spectrophotometric method of Knox[10] from metaphosphoric acid extracts of samples incubated at 37° C. for 60 min. and unincubated controls. The sediments obtained after precipitation with 15 per cent metaphosphoric acid were extracted by Schneider's procedure[11] and the deoxyribonucleic acid was measured by the diphenylamine reaction. Assuming 5×10^{-12} gm. to be the constant deoxyribonucleic acid content of a rat diploid nucleus[12], the results expressed on this basis indicate the activity of tissue per nucleus.

Table 1 shows that there is no manifest change in tryptophan peroxidase activity in the course of 80 days of carcinogen feeding. On the other hand,

Table 1. Effect of Feeding 3′-methyl,4-dimethyl aminoazobenzene on Adaptive Synthesis of Tryptophan Peroxidase

Activity = μmoles of kynurenin formed in 1 ml. homogenate in 1 hr. at 37° C. DNA = μgm. in 1 ml. homogenate. Spec. act. = activity per 5×10^{-12} gm. DNA.

the ability to form new tryptophan peroxidase after the injection of tryptophan declines rapidly in 10 days, and is later either zero or very low compared with the controls. Fractionation of tissue homogenized in isotonic sucrose has shown that tryptophan peroxidase is present only in the soluble phase of the cell, remaining in the supernatant after the components of the broken ergastoplasm have been spun down by centrifugation for 1 hr. at 59,000*g* in the 'Spinco' preparative ultracentrifuge. Thus, feeding the carcinogen, rather than inhibiting tryptophan peroxidase, prevents the cell from forming new soluble protein.

In order to decide whether the drop in adaptive enzyme formation is due to structural damage or to a block of the enzyme-forming system we administered single massive doses of the carcinogen (40 mgm. in 10 ml. corn oil) intraperitoneally to rats kept on a basal diet for four weeks prior to the experiment. The controls were injected with corn oil alone. 17 hr. after intraperitoneal injection half the control animals and half the experimental animals (3 of each) were injected with tryptophan. A parallel test indicated that in animals treated with the carcinogen a large amount of the carcinogen was protein-bound and could be liberated only after prolonged hydrolysis of tissue[6]. Assay, performed 6 hr. after injection of tryptophan, showed a substantial inhibition of tryptophan peroxidase formation in rats which received carcinogen.

We believe that these results provide evidence that 3′-methyl,4-dimethyl aminoazobenzene blocks the synthesis of tryptophan peroxidase, and possibly of other soluble proteins, by the enzyme-forming system of the hepatic cell.

Enterotoxicity of Bacteria-free Culture-filtrate of *Vibrio cholerae*

Two Ogawa strains of *V. cholerae* maintained for six months in the laboratory by fortnightly subculture on agar slopes, and two Inaba strains maintained similarly for about eighteen months have been used for this study. All the strains, which were smooth, were checked for their identity and particularly for their inability to lyse sheep red blood cells. 5 ml. of an 18-hr. culture of each strain in Dunham's peptone water medium was aseptically transferred to a 1-litre Roux bottle containing 200 ml. of a sterile medium of the following composition and a *p*H of 7·6: 'Bacto-peptone' (Difco), 5·0 gm.; sodium chloride, 0·5 gm.; water, 100 ml.

The bottle was laid flat in the incubator, with a maximum free surface of the medium exposed to the air, for about 18 hr. The liquid culture was spun in a 'Servall' superspeed centrifuge in the cold room (2–4° C.) for 10 min. to throw down the bulk of the bacteria. The supernatant was cleared further by high-speed centrifugation for 20 min. at about 14,000 r.p.m., at about 18° C. The clear supernatant fluid was filtered under suction through a Courtauld (later Oxoid) membrane filter. The filtrate was tested for sterility by inoculating 0·1 ml. into 2 ml. of each of Dunham's peptone water and of nutrient broth and incubating for about 42 hr. If unsterile, it was refiltered until sterile. 1 ml. of the sterile filtrate was injected slowly (taking 45–60 sec.) into the lumen of 4-in. loop of rabbit small intestine isolated by two silk ligatures. Essentially, a previous technique for studying the mechanism of action of *V. cholerae* on the intestinal mucous membrane was followed. A second loop of the same length in the same animal about one foot away from the first, was injected with the control medium (5 per cent peptone) treated in a similar way. Next morning, the animal was killed and changes in the loops were looked for. From the first preparation, three such experiments were performed. Two more preparations from the same (Ogawa) strain and three from each of the remaining three strains were tested once each on rabbit loops.

Each of the fourteen control loops was collapsed, and very little fluid, if any, could be expressed from inside them. All fourteen loops receiving culture filtrates were distended with fluid. Some appeared pale, in others blood vessels on the outer wall looked as if they had been injected, while still others appeared hæmorrhagic. The contained fluid was either like rice water, slightly pink, or definitely red. The volume of the contents was about 10 ml. and showed evidence of the presence of mucus, a few epithelial cells and a variable number of red blood corpuscles. The centrifuged supernatant was alkaline (pH 8–9) and had the following composition: nitrogen, 0·69 mgm./ml.; sodium, 144 m.equiv./l.; potassium, 5·6 m.equiv./l.; chloride, 85 m.equiv./l. Nitrogen was determined by Kjeldahl's method, the others by flame photometry. Cultures of scrapings from the mucous surface of the loops were negative to *V. cholerae*. The histological picture of the wall of the swollen loops was variable and included œdema of the mucosa and/or submucosa, infiltration of the mucous membrane with lymphocytes and occasional polymorphonuclear cells, congestion of the blood vessels and some denudation of surface epithelium. In places, the villi seemed to have disappeared altogether, leaving only a thin strip of mucous membrane still attached to the muscular wall. The control loops did not show any histological change.

Three filtrates prepared from an 18-hr. culture of an Ogawa strain in Dunham's peptone water medium, and one filtrate from each of the other three strains grown similarly did not produce any gross or microscopic change in the rabbit loops.

Further details of the activities of different filtrates will be published elsewhere. I am grateful to the Principal, Medical College, Calcutta, for permission to publish this work and to Dr. D. M. Bose, director, Bose Institute, for giving me full facilities of his laboratories. My thanks are due to Dr. Amitabha Sen for helpful criticisms, to Dr. M. L. Ghose for help in the animal experiments, and to Prof. M. L. Chakrabarty for carrying out the flame photometry.

Influence of L-3′,5,3-Triiodothyronine on the Oxidative Phosphorylation of Tumour Mitochondria

THE tumour cell differs from the normal cell mainly in its strong unco-ordinated growth. As any form of growth is combined with an increased consumption of energy, the tumour cell must consequently possess an increased energy metabolism compared with that of the normal cell. This increased expenditure of energy of the malignant cell cannot be completely explained by substrate oxidation via the tricarboxylic acid cycle, as the respiration of the tumour cell is no greater than that of the normal cell. According to Warburg[1] the respiration of tumour cells is even less than that of corresponding normal cells. As is well known, glycolysis, that is, the reduction of carbohydrates to lactic acid, which takes place also under aerobic conditions, is considered as a source of the additional energy production.

The synthesis of energy-rich phosphate bonds, which is coupled with respiration, is decisive for the energy production of the cell, that is, the so-called oxidative phosphorylation. According to Martius[2], Lehninger[3] and other authors, oxidative phosphorylation can be uncoupled by several substances. In this way the synthesis of energy-rich phosphates is disturbed and the cell suffers from energy deficiency.

Similarly, with regard to the energy metabolism of the tumour cell, it should be possible to disturb its energy balance with uncoupling substances and thus to retard the growth. Now, the vitality of a cell which is disturbed in its energy metabolism is impaired and that cell is inferior compared with other normal cells. Therefore, tumour cell damaged in this way should more easily succumb to the body's defence mechanisms and should also be more effectively influenced by cytostatica or radiotherapy. Starting from this hypothesis, we tested triiodothyronine, which was discovered by Martius[4] and Lehninger[5] to be an uncoupling agent of oxidative phosphorylation. As already reported[6], in optimal concentration it reduces tumour growth. Now it seemed to be essential to prove that triiodothyronine uncouples oxidative phosphorylation of tumour mitochondria, too. This, at first, does not appear to be obvious as its uncoupling effect depends on a 'swelling effect' of the mitochondria[5], but the membrane of tumour mitochondria differs considerably in its permeability from the membranes of normal mitochondria[7] and accordingly an uncoupling effect is not necessarily to be expected.

Table 1 shows the influence of triiodothyronine on the oxidative phosphorylation of mitochondria from Walker carcinoma. The mitochondria were isolated from necrosis-free tumour slices in an isotonic sucrose solution and were employed without previous treatment by triiodothryonine.

The comparatively high phosphorus/oxygen ratios of the tumour mitochondria where triiodothyronine was not added results from their greatly reduced respiration. This is possibly a consequence of the impaired respiration of tumour cells postulated by Warburg[1].

We consider that the considerable increase of X-ray sensitivity in experimental tumours and human cancers after administration of triiodothyronine, as recently demonstrated by Stein and Griem[8], can, partially at least, also be explained by a disturbance in the fundamental processes of oxidative phosphorylation. In addition, our experi-

Table 1. INFLUENCE OF TRIIODOTHYRONINE ON OXIDATIVE PHOSPHORYLATION.

The medium contained: 100 m.moles potassium chloride, 35 m.moles magnesium chloride, 10^{-3} m.moles cytochrome *c*, 12 m.moles keto-glutaric acid as substrate, 21 m.moles potassium dihydrogen phosphate, 10 m.moles adenosine monophosphate, 40 m.moles glucose, 30 units hexokinase and 50 m.moles histidine and hydrochloric acid to neutralize it. Triiodothyronine $7 \cdot 5 \times 10^{-5}$ moles, *p*H 7·4. Each deposit contained also 0·5 mgm. or 2·0 mgm. diphosphopyridine nucleotide. The respiration of the mitochondria was measured according to the Warburg technique, temperature 28° C., duration of experiment 20 min. The phosphate was determined according to Fiske and Subbarow (ref. 8)

Triiodo-thyronine added	DPN added (mgm.)	O_2 uptake (μmoles)	P (μmoles)	P/O	Inhibition (per cent)

A Cytopathogenic Agent from a Mammary Tumour in a *C3H* Mouse that produces Tumours in Swiss Mice and Hamsters

Stewart, Eddy *et al.*[1-3] recently reported that an agent derived from leukæmic *AK* mouse tissue produces a cytopathogenic effect in cultures of mouse embryo cells. Furthermore, after passage in tissue culture, this agent, which they term the S.E. Polyoma virus, produces a variety of tumours when it is injected into newborn Swiss mice and hamsters. This report describes observations on an agent with similar properties but derived from a different source.

Tissue from a mammary tumour in a *C3H*/Jax retired breeder was homogenized in a Potter–Elvehjem homogenizer and centrifuged at low speed. The supernatant was frozen. Later it was thawed, and 0·3 ml. added to a single Carrel flask culture of normal *C3Hf*/HeHa mouse kidney cells maintained in a medium consisting of *CMRL*-1066[4] supplemented with 20 per cent horse serum. An uninoculated sister culture was kept as control. The media were changed on the third and ninth days. A cytopathogenic effect was first observed in the inoculated culture on the twelfth day, and was extreme on the thirteenth day. The culture fluid was centrifuged gently, and 0·1 ml. of the supernatant was added to each of several cultures of mouse kidney cells. Cytopathogenic effects were then observed after 4 days. Ten further consecutive passages were made and at each passage a cytopathogenic effect was seen 3–6 days after the culture was inoculated.

The virus is cytopathogenic for normal kidney cells from two different sublines of *C3H* mice (*C3H*/StHa and *C3Hf*/HeHa), and for kidney cells and embryo cells of Swiss *ICR* mice. It has no apparent effect on kidney cells of monkey or rabbit. It remains cytopathogenic after being kept at − 10° C. for 3 months, or at 37° C. for 3 hr., or at 57° C. for 30 min. It has caused hæmagglutination of normal rabbit and guinea pig erythrocytes in titres to 1 : 2560.

Tissue culture fluid from the fifth passage was injected into 50 Swiss mice on the first or second day after birth. The mice exhibited early stunting and poor hair growth similar to that described in newborn mice injected with the polyoma virus[2]. 45 mice survived to weaning. Tumours were observed from the fourth month after injection. To date, nine months after injection, 16 mice have developed a total of 18 tumours. Eleven had parotid tumours, 3, all virgin females, had mammary adenocarcinomas, 2 had thymic lymphomas, and one had all three types.

53 newborn Swiss mice were injected with fluid from normal cultures of *C3Hf* kidney cells. Of these, 48 survived to weaning. No stunting was observed in these mice. Five months after injection, a parotid tumour was observed in one, and to date 3 have developed parotid tumours, and one had both a parotid tumour and a thymic lymphoma. The fact that these mice developed tumours suggests that they received some virus. There are at least three possible ways that this could have occurred: (1) the control cultures could have become contaminated with virus from the inoculated cultures; (2) tumour virus could have been present in the *C3H* tissues used to initiate the control cultures, and this would be consistent with the observation of Gross[5] that extracts of normal organs of *C3Hf* mice injected into newborn mice of the same strain can induce parotid tumours; or (3) the newborn mice might have become infected by air-borne virus. In considering these possibilities it should be mentioned that Mirand[6] has also observed tumours to develop in newborn mice injected with control culture material, and Buffett *et al.*[7] have shown that tumours sometimes develop in animals kept in close contact with others that were injected with subcellular particulates from tumours.

Ten of the tumours in our experimental group have been examined in the electron microscope. In two of these, large numbers of extracellular virus-like particles were observed (Fig. 1), and in four others, smaller numbers were seen. The particles were about 110 mμ in diameter, and many had a dense, central nucleoid body. No particles were seen in the remaining tumours. Three tumours that appeared in mice injected with fluid from normal cultures have been examined, and no particles have been found.

Virus from the twelfth passage was injected into newborn Syrian hamsters. A high percentage have already developed tumours, with deaths occurring from these tumours as early as ten days after injection.

Thus we have obtained, from a *C3H* mouse mammary tumour, a cytopathogenic virus with broad tumour-inducing properties. This may be a new tumour virus. But at least two other possibilities must be considered. First, our findings are so

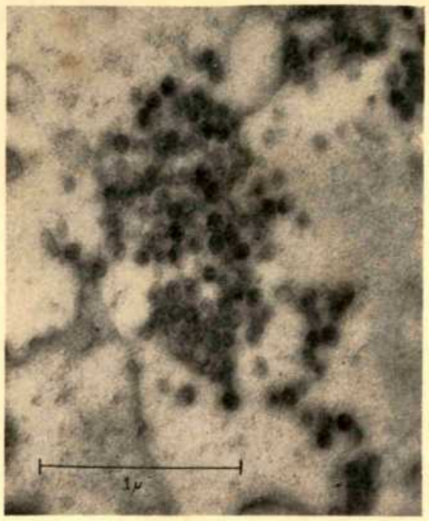

Fig. 1. Electron micrograph showing virus-like bodies in a parotid tumour induced in a Swiss mouse by the cytopathogenic tumour virus derived from *C3H* mouse mammary tumour

similar to those of Stewart and Eddy that they raise the question of whether or not we are dealing with the same virus as theirs. Since we were not carrying the polyoma virus in our laboratory at the time when the injections were made, our preparations could not have been contaminated with polyoma virus. The polyoma virus was obtained from leukæmic tissue of *AK* mice and ours was obtained from a *C3H* mouse mammary tumour. Therefore, if our virus is indeed the polyoma virus, it would mean that the *C3H* mammary tumour and the *AK* leukæmic tissue must have contained the same virus. There is no direct experimental evidence bearing on this point. Secondly, since the tumour from which our extract was made contained the milk agent[8,9] it is possible that this latter virus induced the variety of tumours which we observed. If so, we must assume that passage in tissue culture increased the pathogenicity of the virus to account for the wide tumour-inducing properties not hitherto associated with the milk agent. Finally, it is possible that our results could be accounted for by not one, but a mixture of viruses.

MICROBIOLOGY

Production of Acid from Arabinose and Xylose by Strains of *Azotobacter*

During investigations on the utilization of pentoses by *Azotobacter*, production of acid was observed in many cases in media with arabinose or xylose as sole source of carbon. This acid production is easily demonstrated by inoculation of nitrogen-free agar plates containing 0·5 per cent xylose and 0·5 per cent glucose and undissolved calcium carbonate. In this medium a distinct clear zone develops around the colonies (Fig. 1).

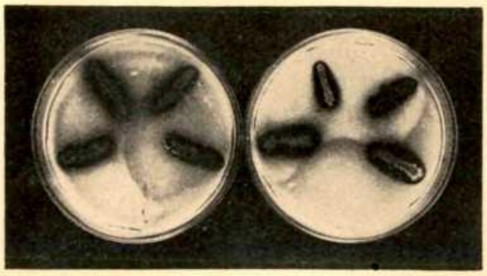

Fig. 1. Nitrogen-free agar plates with 0·5 per cent xylose and 0·5 per cent glucose and undissolved calcium carbonate, inoculated with 10 *Azotobacter* strains, of which eight show acid production

The *Azotobacter* strains were partly stock cultures kept from earlier investigations and partly new isolates from samples of garden soil. The basal medium used had the following composition (gm.): KH_2PO_4, 0·2; K_2HPO_4, 0·8; $MgSO_4 \cdot 7H_2O$, 0·2; NaCl, 0·2; $CaSO_4 \cdot 2H_2O$, 0·1; $Fe_2(SO_4)_3$, 0·01; $Na_2MoO_4 \cdot 2H_2O$, 0·005; 'Bacto' agar 1·0, in 1,000 ml. distilled water, *p*H 7·2. The pentoses were added in concentrations of 0·5 per cent.

*p*H determinations were made with a glass electrode after 14 days incubation at 25° C. The results are recorded in Table 1. Most of the cultures showed no visible growth. Only 5 strains of *A. chroococcum* and 1 strain of *A. beijerinckii* were able to grow well with arabinose as sole carbon source, and xylose was not utilized at all by these species. The strains of *A. vinelandii*, on the other hand, were better able to utilize both arabinose and xylose, although visible growth was in no case accompanied by acid production.

In subsequent experiments with 3 strains of *A. vinelandii*, production of acid, breakdown of xylose, and nitrogen fixation were measured simultaneously (Table 2). The acid produced was determined by back titration to the initial *p*H. Xylose was determined by the method of Somogyi, and nitrogen by the Kjeldahl method. The strains *P*-3 and *P*-4 showed

no visible growth and no nitrogen fixation could be detected, but distinct production of acid had taken place with simultaneous disappearance of xylose. In cultures without calcium carbonate this process was soon inhibited by the acid reaction, and only about one-fifth of the xylose was decomposed with production of about 1 equivalent of acid/mole of xylose. In cultures with calcium carbonate, however, four-fifths or more of the xylose was decomposed. Unlike these two strains, *P*-5 was able to utilize xylose and showed rather good growth. No production of acid had taken place and growth was equally good with or without calcium carbonate.

The decomposition of carbohydrates by *Azotobacter* is not normally accompanied by production of acid, but acid formation may take place in certain circumstances, and a few cases have been recorded previously[1]. Jensen proposes as a possible explanation that strains of *Azotobacter* can oxidize certain carbohydrates to the corresponding sugar acids, but are unable to metabolize these acids further, and this theory is supported by the ratio between acid production and carbohydrate dissimilation in the above experiments. The enzymes concerned with this initial oxidation are probably less specific than those concerned with the later steps of decomposition. No proof of these theories is available yet, but at least it seems clear that the breakdown of carbohydrates by *Azotobacter* follows a scheme different from that of Embden–Meyerhof, with production of acid in one of the initial reactions.

The Phenylalanine Test on Kligler's Iron Agar for the Identification of *Proteus*

BUTTIAUX and his colleagues[1] have questioned the reliability of the urea test for the identification of members of the genus *Proteus* in routine investigations of Enterobacteriaceae. They found many urease-negative *Proteus* strains, and, using Stuart's urea medium[2] they, moreover, detected many urease-positive strains of the genus *Paracolobactrum*.

The Providencia group, now renamed *Proteus inconstans* in the latest edition of "Bergey's Manual of Determinative Bacteriology"[3], is generally urease-negative. All *Proteus* strains, however, are able to deaminate phenylalanine oxidatively to phenylpyruvic acid, a reaction which other members of the Enterobacteriaceae are unable to effect. Buttiaux and his fellow-workers consider the phenylalanine test, which demonstrates this deamination, to be a much more reliable characteristic of *Proteus* than the urea test. Henriksen's[4] method of performing the phenylalanine test, and that of Buttiaux and his colleagues, described in the paper cited above, are too complex and time-consuming for many laboratories. Ben Hamida and Le Minor[5] devised a simple and rapid test using harvested cells from an agar slope, shaken in a buffered solution of phenylalanine; phenylpyruvic acid being tested for, after 10 min. shaking on a Kahn shaker, by the addition of a ferric chloride solution. An intense green coloration was positive, for the presence of phenylpyruvic acid.

This technique seemed admirably suited to adaptation, preferably with the view of extending the use of another diagnostic medium such as Kligler's iron agar, the cells washed from such a culture serving as the suspension for the phenylalanine test.

Forty or so strains of various members of the Enterobacteriaceae, including 18 in the genus *Proteus*, were inoculated on to slopes of Kligler's iron agar, the medium being stabbed to the foot of the tube from the lower angle of the slope.

This method was preferred to the usual one of stabbing the butt from the centre of the slope, for two reasons: (1) the yellow reaction from a positive glucose dissimilation did not spread to the upper half of the tube; consequently no false positive lactose reactions occurred due to incomplete acid reversal on the slope; (2) the blackening of the medium due to the formation of hydrogen sulphide was similarly confined to the butt.

After stabbing, the slope was well streaked out to ensure maximal surface growth for the performance of the phenylalanine test.

The reactions in the Kligler's tubes were read after 18–24 hr. incubation at 37° C. and the cells from each slope were then washed off with 0·5 ml. of a 0·2 per cent L-phenylalanine solution in 0·1 molar phosphate buffer to *p*H 7·4, the cells being removed from the slope into the buffer solution by rubbing with a wire-loop, to obtain the heaviest suspension. This suspension was then poured into a bijou bottle and shaken for 10 min. on a 'Microid' flask shaker.

The shaking was then stopped, 0·1 ml. of an 8 per cent aqueous ferric chloride solution added to the suspension, and the bijou reshaken for 30 sec. or so.

An intense dark green colour was produced in the presence of phenylpyruvic acid. In every case only the *Proteus* strains gave this positive reaction. The other strains produced yellow or brownish reactions. The results obtained with the strains using the phenylalanine method of Buttiaux *et al.*[1] agreed entirely with these results.

The presence of sulphides in Kligler's medium did not interfere with either the performance or the reading of the test.

The advantage of using one medium for as many reliable tests as possible is obvious when one considers the increased risks of contamination involved in taking two 'picks' from any one colony on a selective plate, to inoculate two tubes of media.

To inoculate a separate slope for the phenylalanine test from a cultured Kligler slope means that there is an 18–24 hr. delay before a rapid phenylalanine test, such as Ben Hamida and Le Minor[5] suggested, can be carried out.

The extremely simple extension in the use of Kligler's medium outlined above to include the phenylalanine test should prove of value where speed of diagnosis is essential.

Other multiple sugar media could presumably be so utilized instead of that of Kligler.

A Group of Pseudomonads able to synthesize Poly-β-hydroxybutyric Acid

POLY-β-HYDROXYBUTYRIC acid has been found to occur very infrequently in *Pseudomonas* although it is very common in the related genera *Chromobacterium*, *Spirillum* and *Vibrio*[1,2]. It is absent in authentic strains of *P. aeruginosa*, *P. fluorescens*, *P. aureofaciens*, *P. convexa*, *P. schuylkilliensis*, *P. pavonacea*, *P. lemonnieri*, *P. mildenbergii*, *P. syncyanea* and *P. chlororaphis*. Of classified strains tested it only appears to be present in the animal and the plant pathogens, *P. pseudomallei*[3] and *P. solanacearum*, which are scarcely typical of the genus. It has also been found in *P. antimycetica*[4] and a group of related organisms, which appear to be pseudomonads, referred to in previous publications[1,2] as "pseudomonads related to Hankey Culture Collection (HCC) B175". This group has now been studied in some detail and should, we feel, be considered members of *Pseudomonas*.

The strains were isolated mainly from Trinidad soils on glucose–'Marmite'–peptone agar plates. They form characteristic opaque yellow colonies which in some strains change after 2–3 days to an intense reddish-purple colour. They are all non-sporing, non-acid-fast, Gram-negative rods, 0·7–1·3μ × 0·4μ, occurring singly or in pairs; motile by means of a polar tuft of flagella varying from 3 to 8 in number. They are aerobic. They grow well at 37° C. and to some extent at 42° C. They will not grow below 15° C. All strains rapidly liquefy gelatin and peptonize milk. Citrates are utilized as the sole source of carbon. Neither indole nor acetoin is formed. Cellulose is not attacked.

The group is characterized by the production of massive inclusions of poly-β-hydroxybutyric acid on media containing a readily available energy source, and the production of a diffusible fluorescent pigment in asparagine–salts media[5] giving a violet fluorescence in ultra-violet light easily distinguishable from the bluish-green fluorescence of the normal fluorescent pseudomonads listed above. The strains all grow rapidly in a lactate salts medium. They have an oxidative metabolism[6] and rapidly oxidize glucose, sucrose and lactose. Their fermentative ability is weak—slight acid, no gas, from glucose but not from other sugars. They are strongly lipolytic. They hydrolyse æsculin but not starch.

They form two clearly defined sub-groups on the basis of pigment formation and nitrate reduction (Table 1).

Production of the purple pigment was examined. The best medium for pigment production was glycerol–peptone (2 per cent glycerol, 1 per cent peptone ('Oxoid'), 0·5 per cent sodium chloride, 0·1 per cent potassium nitrate). Strong aeration is essential. 1 litre of the above medium was inoculated with strain *B*175 and grown for three days in shake flasks. The purple pigment is insoluble in water and the usual organic solvents. The cells and pigment were therefore recovered by centrifuging and dried. The dried cells (about 10 gm.) were extracted with chloroform in a solvent extraction apparatus for 18 hr. The chloroform solution contained a small quantity of a yellow-green pigment and 3·1 gm. of poly-β-hydroxybutyric acid, m.p. 168° C. The residue was blended with 95 per cent ethanol containing 2 per cent v/v concentrated hydrochloric acid. This treatment causes the insoluble purple pigment to change to a yellow form soluble in organic solvents.

The purple form can be re-formed by making the solution alkaline. The alcohol extracts were concentrated to small volume and water added. The yellow pigment was extracted from the water layer with chloroform. The chloroform solution was chromatographed on silica gel, considerable dark-coloured material remaining adsorbed while pure pigment was eluted. The pigment was recrystallized from a benzene–*cyclo*hexane mixture as orange-yellow

* This isolate has already been studied by Sneath (designated by him *T*1, ref. 7)

needles, m.p. 237–238° C. (2·5 per cent yield). (Found: C, 58·0; H, 3·8; O, 28·7; N, 8·5; OCH_3, 9·3; NCH_3, 8·9 per cent; molecular weight, 340. Calculated for $C_{1}H_{12}N_{2}O_{6}$: C, 58·5; H, 3·7; O, 29·2; N, 8·5; 1-OMe, 9·4; 1-NMe, 8·9 per cent; molecular weight, 329.) Hydrolysis of the pigment with 2 *N* sodium hydroxide for 20 hr. yielded a red acid, m.p. 284° C. Zinc dust distillation of this acid gave a yellow-brown distillate from which phenazine (identified by melting point and ultra-violet spectrum) was isolated by crystallization and sublimation. The original pigment depressed the melting point of an equal quantity of phenazine-α-carboxylic acid by 40 deg. C., indicating the non-identity of the two compounds. The absorption spectrum of the pigment differs markedly from the spectra of violacein, pyocyanin, chlororaphin, iodinin, phenazine-α-carboxylic acid[8], and the blue pigment from *P. lemonnieri*[9]. The chemical structure of this new phenazine pigment is being studied.

The organisms are therefore a group of Gram-negative, polar-flagellated rods of oxidative metabolism. They produce a diffusible fluorescent substance and the pigmented members produce phenazine pigments. Following Tobie[10], they should be included in the genus *Pseudomonas*.

GENETICS and CYTOLOGY

Two New Basic Chromosome Numbers in the Musaceae

The scheme proposed by Cheesman[1], and now generally accepted, for the classification of the Musaceae depends partly on basic chromosome numbers. Two genera are recognized. The genus *Ensete* Horan. comprises species with monocarpic habit and $2n = 18$ chromosomes. Species of *Musa* L. form suckers more or less freely and are placed in four sections: Musa (Eumusa) and Rhodochlamys with $2n = 22$, Callimusa and Australimusa with $2n = 20$. This scheme includes nicely all the species thus far described, but among recent introductions to the Trinidad collections are two exceptional forms for which the classification will need to be elaborated.

Somatic chromosome counts were made from root tips by the method of Tjio and Levan[2].

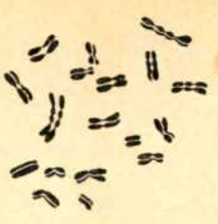

Fig. 1

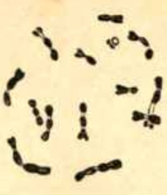

Fig. 2

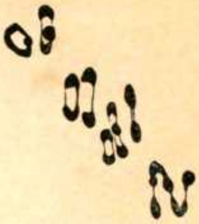

Fig. 3

Fig. 1. Somatic chromosomes of *I.R.* 503. (× 2,300)

Fig. 2. Somatic chromosomes of *I.R.* 510. (× 2,300)

Fig. 3. First meiotic metaphase in *I.R.* 503, showing a chain of four and seven bivalents. (× 2,300)

The first introduction, *I.R.* 503, is a seed collection from British North Borneo and is fairly certainly the unknown species noted by Simmonds[3], on the basis of herbarium material, as probably a new Rhodochlamys. Living plants, however, are more reminiscent of Callimusa; they differ from Callimusa spp. in seed characters and in the chromosome number, which is $2n = 18$ (Fig. 1). The second, *I.R.* 510, comes from the highlands of north-central New Guinea and is probably the largest herb in existence[4]. It has largish seeds, reminiscent of *Ensete*, but in some other respects resembles *Musa*. In its sparse suckering, especially if the leading stem is damaged, it is more or less intermediate between the two genera. The chromosome number is $2n = 14$ (Fig. 2). In neither case has the proper taxonomic position been decided, but at least one new section and perhaps a new genus can be envisaged. Indeed, it appears that a study of the wild bananas of the Indonesian area, still partly unknown, might enlarge the family considerably.

Only *I.R.* 503 has so far flowered in Trinidad and meiosis has been examined in acetocarmine smears of pollen mother cells of one plant. Chains of three or four chromosomes were seen at metaphase in occasional cells, indicating heterozygosity for a small translocation (Fig. 3). Structural diversity of this kind is frequently encountered in *Musa*. Translocation hybridity has been reported in cultivated clones of Eumusa, in hybrids between 22-chromosome species and in hybrids between geographical races of *M. acuminata*[5–7]. More recently, I have found (unpublished work) that homozygous translocations are distributed among the geographical sub-species and races of *M. acuminata* on a scale comparable with that found in *Gaillardia*[8], and have noted multivalents in several new crosses of 22-chromosome species and in one Australimusa hybrid. However, despite this high frequency of occurrence in edible bananas and in experimental hybrids, the present case is the first in which heterozygosity has been recorded in a wild collection. There is no evidence as to whether the translocation is a recent one or has been revealed by the mingling of already diverse populations.

Nuclear Fusion and Non-Fusion in *Theobroma cacao* L.

CYTOLOGICAL investigations carried out on *Theobroma cacao* have revealed the fact that the incompatibility reaction in this species is based on non-fusion between male gametes and female haploid nuclei carrying the same dominant S allele[1]. Incompatibility pollinated cacao ovaries contain approximately 25, 50 or 100 per cent of ovules wherein fusions between the first male gamete and the egg nucleus and between the second male gamete and the polar nuclei have not taken place. In such ovules, the egg and male nuclei appear always to lie in actual contact, each preserving its spherical shape; the second male gamete and the polar nuclei, however, do not show such regularity of behaviour, for the two polar nuclei may sometimes become dissociated from one another, the male nucleus lying elsewhere in the embryo-sac or in contact with one of the separated polar nuclei.

When fusion does take place between a male gamete and the polar nuclei, the male gamete invariably places itself at some point on the line of juncture of the two polar nuclei, so that the male nucleus lies in simultaneous contact with both female nuclei before fusion takes place. The male gamete appears not to fuse at random over the surface of one or other of the polar nuclei but always comes into the position where all three nuclei are in mutual contact. The male nucleus then insinuates itself between the polar nuclei, assuming a more and more fusiform shape as it penetrates. Finally, the contents of the male nucleus mingle with the nucleoplasm of one of the polar nuclei. The process is shown in diagrammatic form in Fig. 1.

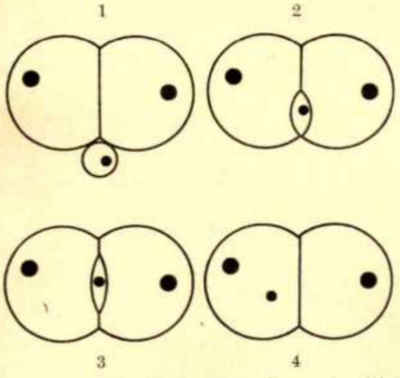

Fig. 1. Four stages in the fusion of a male gamete with the polar nuclei in cacao (diagrammatic)

This fusion behaviour can be likened to the coalescence of oil droplets in an extremely unstable oil/water emulsion; here the fusing oil droplets tend to share large areas of their surfaces and hence assume a polyhedral form[2]. The male nucleus, originally spherical (as is a single oil droplet), arranges itself between the polar nuclei in such a manner that its entire surface is shared with these two nuclei. Fusion with one or other polar nucleus is a purely random process.

In the case of non-fusing nuclei, entirely different interfacial conditions must exist and the system can be likened to a stable oil/water emulsion in which no coalescence of the oil droplets takes place. In emulsions stabilized, for example, with a protein, direct oil-to-oil contact between droplets is prevented by the presence of a monolayer of adsorbed protein at the surface of each droplet. This condition does not imply that the stabilized droplets cannot make contact, but rather that when contact is made they preserve their spherical form. Clusters of spherical oil droplets can be seen under the microscope in many emulsions.

The not infrequent separation of the two polar nuclei in ovules showing non-fusion leads us to suggest that this effect is brought about by the presence of a strongly but specifically adsorbed substance in the cytoplasm of the male nucleus carrying the dominant S allele. When both male and polar nuclei carry the same dominant allele (for example, S_1 nuclei in in $S_{1\cdot 2}$ selfed or in $S_{1\cdot 2} \times S_{1\cdot 3}$), the substance which 'interferes' with nuclear fusion diffuses from the male cytoplasm into that associated with the polar nuclei, from which it interacts with specific sites on the surface of both polar nuclei, leading to protection against fusion (or stabilization of all three bodies). In these circumstances the separation of the nuclei is understandable.

No specific adsorption sites, apparently, are present at the surface of polar nuclei which carry the recessive allele (for example, S_2 nuclei in the $S_{1\cdot 2}$ genotype) for fusion with any male nucleus will always take place. When the polar nuclei carry a dominant S allele different from that of the male gamete, fusion again will ensue; for example, S_3 polar nuclei in an $S_{3\cdot 4}$ genotype will fuse with S_1 male gametes derived from an $S_{1\cdot 2}$ genotype because the S_3 sites are not specific adsorption sites for the S_1 protective substance. If the male nucleus does not carry a dominant S allele, no protective substance is present in its cytoplasm; it will therefore always fuse with any female nuclei.

In view of the specificity of the non-fusion reaction, the protective substance is likely to be proteinaceous in character.

Genetics of Dieldrin Resistance in *Lucilia cuprina* Wied.

IN a comprehensive paper on insecticidal resistance in anopheline mosquitoes Davidson[1] demonstrated that resistance to dieldrin in *Anopheles gambiae* is due to a single gene, partially dominant. In this work the discriminating dose technique, supported by Milani[2], for genetical studies on insecticidal resistance in insects was utilized.

Employing this method in a study of the genetics of dieldrin resistance in *Lucilia cuprina*, in which insecticidal resistance has been demonstrated[3], it is indicated that dieldrin resistance in this insect is also due to a partially dominant single gene. To date information is available only from a cross between susceptible female flies and a single resistant male fly. The results, however, conform so closely to a Mendelian interpretation on a single gene basis that it can be expected that additional work will merely confirm the above conclusion.

In this preliminary study a single resistant male fly, which survived 4 μgm. of dieldrin, was crossed with ten susceptible female flies. The male fly was taken from a strain of flies undergoing selection in an attempt to develop a homogeneous strain of blowflies for genetical studies.

The male and female $F1$ progeny of the initial cross were intermediate in resistance. A dosage of 0·1 μgm. dieldrin/fly (the dose which consistently kills all susceptible flies) gave no mortality, while 4 μgm. dieldrin/fly gave complete mortality. Application of the discriminating dose (0·1 μgm. dieldrin/fly) on both males and females of the $F2$ resulted in close agreement with a 1 : 3 ratio (1 dead : 3 alive). The tests were made on 1,007 flies. The above ratio applied more closely to female than male flies.

In the back-crosses an approximate 1 : 1 ratio and complete survival resulted when the discriminating dose of 0·1 μgm. of dieldrin was applied to the progeny of $F1$ females × susceptible male (287 flies) and $F1$ females × resistant male (136 flies) respectively. Flies of both sexes were again treated.

The insecticide, dissolved in kerosene, was applied topically with a micro-applicator which delivered 0·5 μl./fly.

Thanks are due to Dr. J. R. Busvine of the London School of Hygiene and Tropical Medicine and R. Milani of the Zoological Institute, Pavia, Italy, for suggestions regarding this work. Acknowledgment is also made of assistance given by R. Hart of Geigy A/Asia (Pty.) Ltd.

Amounts of Deoxyribonucleic Acid in the Silk Glands of the Spider *Nephila maculata*, Fabr., 1763

THE major chemical components of a chromosome so far described are two types of protein and deoxyribonucleic acid. The amounts of the two types of chromosomal protein vary considerably between the tissues of one animal[1]. Deoxyribonucleic acid content is much less variable, however, and appears[2-4] to be approximately constant in the nuclei of the same species. However, recent work by Leuchtenberger and Schrader[5] indicates that the quantities are likely to vary in secretory tissues.

In the course of this investigation the silk glands of *Nephila maculata* were selected for analysis. There are five types of silk glands in this spider, namely : (1) aggregate glands ; (2) ampullate glands ; (3) cylindrical glands ; (4) aciniform glands ; and (5) pyriform glands. All these glands are highly secretory and are concerned with the production of silk for the construction of the web.

The tissues were removed from freshly killed animals as quickly as possible and were fixed in Carnoy's acetic alcohol (3 parts of absolute alcohol : 1 part of glacial acetic acid). The fixation period was usually 4 hr. The fixative was then thoroughly washed off the tissues, which were then embedded in paraffin, cut at varying thickness, and stained with Feulgen stain as described by Stowell[6].

Measurements were made on an apparatus similar to that described by Pollister and Moses[7], with an *RCA* 931*A* electron multiplier phototube and a light source consisting of a tungsten ribbon filament lamp, from which the 546-mμ wave-length was isolated by the Farrand interference filter (peak 550 mμ) to estimate the Feulgen reaction. Readings were taken on a 'Rubicon' galvanometer. The final values in arbitrary units were obtained as described by Swift[8].

Table 1

Cell type	No. of nuclei measured	Volume of nuclei (μ^3)	Deoxyribonucleic acid (arbitrary units)
Aggregate gland	49	36·810 ± 11·453	2·339 ± 0·444
Ampullate gland	49	44·525 ± 15·058	2·495 ± 0·477
Cylindrical gland	49	29·981 ± 6·082	2·475 ± 0·397
Aciniform gland	49	31·535 ± 6·260	2·435 ± 0·461
Pyriform gland	50	42·662 ± 13·23	2·891 ± 0·595

Table 1 gives the results obtained by photometric estimations.

It will be seen that there is considerable variation in the volume of the nuclei from different silk glands. Even in the nuclei of the same gland the deviation is quite significant. This is indicative of the differential secretory activity in the nuclei, as the volume of the nuclei will be directly related to the accumulation of the products of secretion liberated into the cytoplasm. On the other hand, the quantities of deoxyribonucleic acid are remarkably constant not only in the nuclei of the same gland but also in the nuclei of the different glands. This indicates that the quantities of deoxyribonucleic acid are not directly related to the secretory activity of the nucleus. This finding is in agreement with the hypothesis of constancy, but differs from the observations of Leuchtenberger and Schrader[5], who find that the quantities of deoxyribonucleic acid in *Helix*, though generally constant in body tissues, are likely to vary in secretory tissues. The decrease of deoxyribonucleic acid in the nuclei of the salivary gland of *Helix* is, according to Leuchtenberger and Schrader, the result of its utilization in the formation of secretory products in the cytoplasm. In *Nephila*, however, the amount of deoxyribonucleic acid is constant and does not bear any direct relation to the secretory activity.

HYDROLOGY

Marine Studies in the Inshore Waters of Antarctica near Mawson, 1956

THIS investigation, aimed at obtaining information concerning the hydrology and biology of the inshore waters of Antarctica, especially during the winter period, formed part of the scientific programme of the 1956–57 Australian National Antarctic Research Expedition to Mawson (67° 31′ S. lat., 62° 53′ E. long.) in MacRobertson Land. After a period of establishment, I began regular observations in June and continued at weekly intervals until February

1957. Two stations were occupied, one in 25 m. and the other in rather more than 100 m. of water. Observations were made at various depths throughout the water column. For the greater part of the period the surface was frozen to a maximum recorded depth in September of 115 cm. Water samples were taken in the normal manner with Nansen bottles but using modified operating techniques to meet the severe conditions. Plankton hauls, mainly vertical and entailing considerable difficulty, were run with $N50$ and $N70$ nets.

From the water samples, and in addition to records of temperature, measurements were obtained of pH, E_h, buffer capacity, dissolved phosphates and oxygen, and chlorinity. Measurements of submarine solar radiation were taken down to a maximum depth of 10 m. A high-speed continuous centrifuge was used to extract phytoplankton both for the determination of chlorophyll and for qualitative and quantitative examination.

Although the results are too extensive to be described in detail in this communication, it may be of interest to indicate briefly some of the features of particular interest. Chlorinity values obtained during winter were low, mean figures ranging from $16{\cdot}00$ to $18{\cdot}70\,^{0}/_{00}$. These chlorinities, combined with mean temperatures between −1·90° C. and −1·60° C., commonly produced freezing conditions extending well down into the water column and appeared to cause the formation of ice crystals in free suspension, apart from the sea ice formed at the surface. Chlorinities were appreciably higher during summer except for a temporary shallow surface zone of extremely low salt content produced by the melting of the sea ice. Evidence was obtained which indicates a process by which the summer waters undergo incomplete mixing and remain close to the coastline until their replacement by relatively homogeneous water of higher chlorinity with the onset of the following summer.

As might be expected in these latitudes, the incidence of submarine solar radiation was found to exhibit marked seasonal differences, being negligible during the long winter period partly because of the low elevation of the Sun and partly because of the highly reflecting layer of sea ice. Consequent upon such conditions, phytoplankton was virtually absent during the winter period although small numbers of zooplankton organisms were taken in the nets. It is of interest that phytoplankton appeared and began to increase and attached diatoms were found actively growing on the under surface of the sea ice while the ice itself was more than 100 cm. thick. Large-scale blooms did not occur, however, until the ice was in an advanced stage of disintegration during the thaw.

The striking qualitative differences between the phytoplankton extracted with the continuous centrifuge and that taken with the nets was particularly illuminating, especially as the greater part of the chlorophyll estimated must have been contributed by forms either rare or absent in the material gathered by conventional methods. Based on chlorophyll concentrations, it was estimated that the carbon content in the standing crops of summer phytoplankton lay between $0{\cdot}30$ and $14{\cdot}80$ mgm./m.^{3}.

Full details of the above investigation will be published elsewhere.

ARCHÆOLOGY

Apple-Scoops

Being a private collector of items relating to bygone dentistry, I was naturally interested to read Prof. Raymond A. Dart's communication (*Nature*, March 21, p. 844) on "An 'Australopithecine' Scoop from Herefordshire".

Apple-scoops (occasionally termed gouges) were freely used in apple-growing districts by edentulous persons to scrape small thin pieces off the fruit and thus facilitate mastication. This custom was particularly prevalent prior to the introduction into Great Britain, in 1855, of vulcanite as a base for artificial dentures. Until then, such restorations were expensive due to the time and labour necessary to carve them from hippopotamus or walrus tusks with the precision that would ensure an accurate fit: the alternative being natural or ivory teeth attached to a swaged gold foundation.

The most popular apple-scoops were undoubtedly home-made and fashioned from the metacarpus or metatarsus of sheep. Others were constructed of ivory. A silver (Birmingham hallmark 1830) specimen, which I possess, unscrews from its hollowed ivory handle and fits into this for portability. Incidentally, there is a small but very comprehensive collection of apple-scoops in the Folk Museum, Gloucester.

METALLURGY

Ductile Cleavage Fracture of Molybdenum

Most metals other than those having a face-centred cubic structure show a more or less rapid transition from ductile to brittle behaviour as the temperature is lowered. Well above the transition temperature the fracture surfaces are mainly fibrous with only a few cleavage facets, but at intermediate temperatures fracture occurs by cleavage after a strain of a few per cent. So far little attention has been paid to the mechanism of this ductile cleavage fracture. Recently, we have examined cleavage facets and longitudinal sections of a number of fractured specimens in which cleavage occurred after straining about 10 per cent at room temperature at a rate of strain of $0{\cdot}88 \times 10^{-4}$ sec.$^{-1}$. The tensile specimens, which had grain diameters of about 2 mm., were prepared from arc-cast deoxidized molybdenum and were 0·1 in. in diameter[1]. The results throw some light on the mechanism of fracture.

Part of a typical fracture edge is shown in Fig. 1. It is made up mainly of straight-line segments which often occupy one complete grain (see *A* in Fig. 1). Within about 0·5 mm. of each fracture edge a number of subsidiary cracks are observed (see *B* in Fig. 1) and often these are arranged in a characteristic configuration, an example of which is shown in Fig. 2. The cracks do not cross grain boundaries and those making up a configuration are always contained in one grain. Occasionally an 'ear', such as that shown at *C* in Fig. 1, is observed on the edge of the fracture. Such ears have been shown to be the result of the joining of two overlapping cracks on different cleavage planes by the shearing of the material

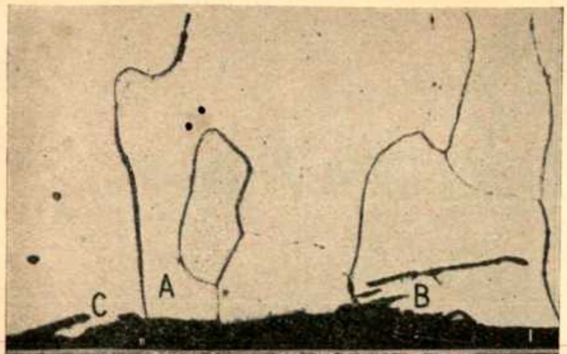

Fig. 1. Longitudinal section through the fracture surface of a molybdenum specimen which fractured after 10 per cent strain at room temperature. (× 250)

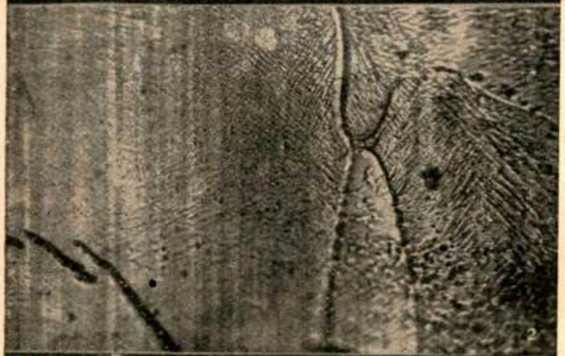

Fig. 2. A similar specimen to that of Fig. 1, but electro-etched, showing wavy slip lines and 'forced slip' near the grain boundaries. (× 250)

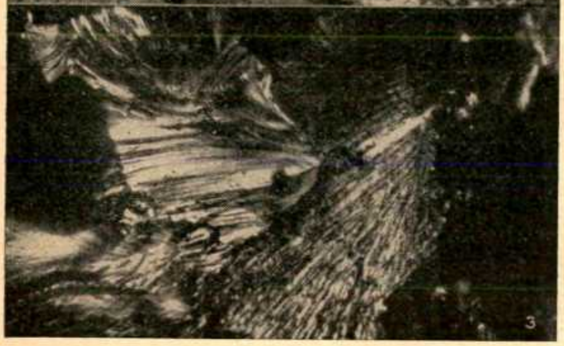

Fig. 3. Photograph of some cleavage facets on the fracture surface of a specimen similar to those shown in Figs. 1 and 2. (× 250)

between them[2]. The markings on the cleavage facets (Fig. 3) suggest that the growth directions are different for each crack.

We believe that these results show that fracture occurs by the joining of many cracks which grow co-operatively in a narrow band across the specimen. The grain boundaries provide barriers which are sufficient to prevent their propagation, and the final stage of the fracture is one of shearing at or near the grain boundaries to form the complete fracture surface. Some of the cracks are not needed to form the fracture surface, and these are left after fracture as subsidiary cracks such as those in Figs. 1 and 2. The existence of configurations of cracks such as that in Fig. 2 shows that cracks can occur on more than one crystallographic plane, even within one grain.

The wavy slip lines shown in Fig. 2 were revealed by electro-etching and are characteristic of body-centred cubic metals. Near the grain boundaries, 'forced slip' has occurred on intersecting slip systems and this would be expected to increase still further the difficulty of propagating a crack through a grain boundary.

A more detailed study of this type of fracture is being made and will be reported elsewhere. The work is being carried out while one of us (A. A. J.) is holding a University of London I.C.I. Research Fellowship and the other (B. J. S.) a U.K. Atomic Energy Authority Research Bursary.

A New Silicide in a 12 per cent Chromium Steel

In the course of an investigation into the tempering characteristics of a 12 per cent chromium steel (C 0·098, Mn 3·18, Si 3·02, Ni 4·06, Cr 12·56, Mo 0·49, V 1·09 per cent) a new phase was discovered. This phase (which we have called *H*-phase) could not be obtained in isolation but was always associated with $M_{23}C_6$. A residue extracted after tempering the steel for 50 hr. at 750° C., however, gave the maximum proportion of the new phase to $M_{23}C_6$. This was of the order of 2 : 1. This residue was examined in more detail by X-rays and a full chemical analysis was obtained.

The specimen was photographed in a 9-cm. diameter powder camera and a quadruple focusing camera, cobalt $K\alpha$ radiation being used in both cases. The interplanar spacings of the new phase fitted a cubic lattice with $a = 10{\cdot}735$ kX. The interplanar spacings are listed in Table 1, together with line intensities and indices. The X-ray pattern of the new phase shows marked resemblances to the pattern of M_6C. The space group of the new phase is probably *Fd*3*m*.

The full chemical analysis, converted to atomic percentages, is shown in Table 2. Due to the presence of $M_{23}C_6$ it is very difficult to form any definite conclusions about the composition of the new phase

PHYSICAL SCIENCES

An Effect of Oxide Layers on the Behaviour of Vacuum Arc Cathode Spots

IN the course of a preliminary experiment to study the effect of electrode surface condition on the behaviour of the cathode spot of a d.c. vacuum arc an interesting phenomenon was observed.

The surface of a vacuum-cast copper cathode was prepared by abrasion on emery paper and hand polishing on a 'Selvyt' cloth. After degreasing in a petroleum ether still, the surface was cathodically etched in argon and the grain boundaries were clearly revealed. The surface was then oxidized to cuprous oxide by heating in air.

The d.c. arc discharge was struck by touching a pointed tungsten anode on to the prepared surface, both electrodes being mounted in a glass vacuum chamber exhausted to 0·01μ mercury pressure. A mechanical switch shorted the arc after 20 millisec.

The cathode spots left characteristic continuous tracks on the electrode surface, and it was found that the markings were absent from certain grains as shown in Fig. 1. The characteristic tracks stop abruptly at the grain boundaries and it appears that the cathode spot is able to operate more easily on some grains than others, and a definite preferential action was observed.

This effect occurred when the current flowing before the electrodes were separated was 5 amp., and did not occur when the arc current was greater, for example, 50 amp. short-circuit current.

The λ-Transition in Helium

RECENT experiments on the inelastic scattering of neutrons by superfluid helium[1,2] have given a direct confirmation of the correctness of the elementary excitation spectrum (rotons and phonons) of Landau's theory[3]. As it is usually formulated, the theory postulates that the excitation spectrum is independent of temperature. However, the velocity of sound is known to vary somewhat with temperature[4], and the neutron scattering experiments[1] show an appreciable fall in the minimum roton energy Δ, as the temperature approaches the λ-point.

It is possible to understand the non-existence of superfluidity above the λ-point if one has reason to believe that Δ vanishes at the λ-point[5]. But if Δ really were to vanish at the λ-point, it would almost certainly imply the existence of an Ehrenfest[6] second-order transition, that is, a finite discontinuity in the specific heat. Recent measurements of the specific heat of liquid helium[7] show a more complicated anomaly—a finite discontinuity is superimposed on a logarithmic infinity.

A phenomenological model can easily be constructed for the dependence on temperature of Δ, leading to a specific heat anomaly of the kind observed, while agreeing closely with the observed $\Delta(T)$ within the temperature region covered by the neutron scattering experiments[1]. One such model for $\Delta(T)$ is :

$$\left.\begin{aligned} \Delta &= \Delta_0, & \xi &< -1 \\ &= \Delta_0(|\xi| + \xi\ln|\xi| + e^{-2})/(1 + e^{-2}), & -1 < \xi &< e^{-2} \\ &= 0, & \xi &> e^{-2} \end{aligned}\right\} \quad (1)$$

where

$$\xi = \alpha(T/T_\lambda - 1), \quad (2)$$

and the constant of proportionality α is to be chosen to give the best fit with experiment.

Fig. 1 illustrates the postulated behaviour of Δ (where the scale factor α in equation (2) has been put equal to 4); for comparison the experimental points of Larsson and Otnes[1] are also shown. The specific heat anomaly arises from the singularity in $d\Delta/d\xi$ at $\xi = 0$. This derivative has a finite discontinuity and a logarithmic infinity, and the ratio of the coefficient of the logarithm to the magnitude of the discontinuity is $\frac{1}{2}$. The experimental value[7] of this ratio is $\sim 0{\cdot}3$.

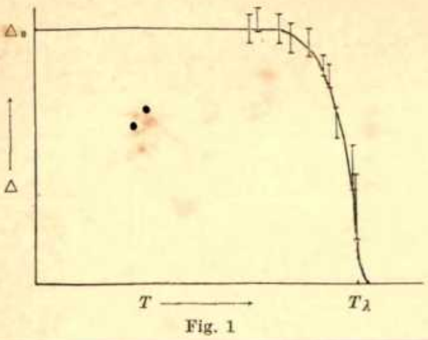

Fig. 1

If this phenomenological model has any significance, it implies that Δ does not vanish at the transition, but falls rapidly to zero for values of ξ slightly greater than zero (up to $\xi \sim 0\cdot 1$). It might be hoped that inelastic neutron scattering experiments in a temperature region containing the λ-point (say, 2·0 to 2·3° K.) could test the present suggestion; unfortunately the results reported suggest that the line width becomes prohibitively great near the λ-point.

The form of $\Delta(\xi)$ may well be more complicated than is proposed here—equation (1) has discontinuous second derivatives at $\xi = -1$ and at $\xi = e^{-2}$ which would give spurious Ehrenfest third order transitions at these temperatures. If Δ is indeed finite above the λ-point, then the value of Δ can fulfil the role of the short-range order parameter in an order–disorder transition. The absence of superfluid behaviour immediately above the λ-point will, however, require a separate explanation, and may possibly be linked with the increasing line-width for neutron scattering.

Townsend's First Ionization Coefficient in Pure Nitrogen

With equipment assembled for the measurement of Townsend's α in highly pure hydrocarbon gases, it was thought interesting to carry out preliminary but careful measurements in a common diatomic gas. Now that satisfactory agreement has been reported for hydrogen[1,8] which does not depend too critically on purity, it was hoped to confirm the latest results in pure nitrogen obtained by Harrison[2], which differ from all other workers (and those to be presented here) by up to an order of magnitude.

Previous results[3–8], corrected to 0° C., are shown in Fig. 1. Excepting the values of Ayers[3], overall agreement is reasonable (within 30 per cent, later results agreeing better) considering the unspecified nature of possible contaminants present in each case. As a reference, the values of Masch will be used[4] because, among other reasons to be given, his results provide a consistent set of values taken over a wide pressure range and cover the whole E/p_0 region under consideration. Bowls's[6] values, though obtained with a mercury-free system, only cover the higher E/p_0 region.

As shown, Harrison obtained values for (*a*) 99·99 per cent nitrogen, obtained from sodium azide; (*b*) 99·9 per cent purified cylinder nitrogen (0·06 per cent oxygen, 0·04 per cent argon, obtained by passing gas (*c*) through hot copper and a liquid nitrogen trap); (*c*) 99·9 per cent cylinder nitrogen. His results indicate that: (1) the presence of 0·1 per cent of common impurities such as oxygen or argon lowers α/p_0 by from 30 to 3 per cent; (2) the presence of a further $\simeq 0\cdot 1$ per cent of some other contaminant found in cylinder nitrogen and removed by liquid nitrogen lowers α/p_0 by another 35 per cent. These rather large effects would satisfactorily account for previously found discrepancies and would indicate that Masch's results should compare favourably with Harrison's (*a*) curve. Comparing the absolute magnitude of these two sets of results, however, reveals a discrepancy by a factor of 2–10; even using Harrison's (*c*) results still gives a discrepancy of 2–6 times. A shift in the E/p_0 axis of about 10 would give almost perfect agreement all round.

Values of mine obtained in 99·998 per cent nitrogen are also shown in Fig. 1 (impurities: $O_2 < 10$ vol./million; $CO_2 < 5$ v./m.; $H_2 < 1$ v./m.; $A \leqslant 5$ v./m.; gas supplied by B.O.C. Ltd.). These were obtained in a $\frac{3}{4}$-litre system incorporating ultra-high vacuum techniques and which will be described elsewhere. To make optimum use of the variable 0·2–1·2 cm. parallel-plate gap, the pressure of the samples covered 50–400 mm. mercury. Mercury contamination was completely eliminated using a differential pressure device. Conditions were such that no impurity greater than that originally present

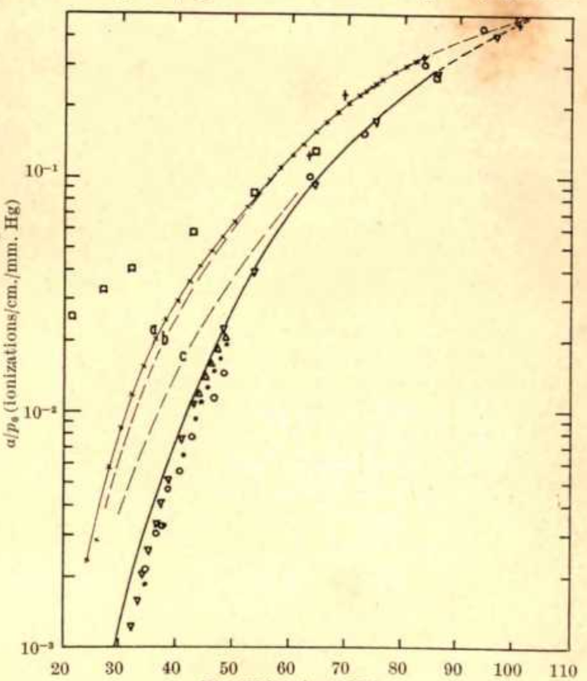

Fig. 1. Full curve, present work; □, Ayers; ▽, Masch; ○, Posin; +, Bowls; △, Dutton, Haydon and Llewelyn Jones; ●, de Bitetto and Fisher; ×, Harrison (*a*, *b*, *c*)

in the sample could possibly have been added. The use of a liquid-nitrogen trap in the gas supply line did not affect the results.

It is seen that the curve coincides with the values of Masch except at very low E/p_0. This agreement may seem surprising as the results of Masch were obtained in 99 per cent nitrogen in a mercury-contaminated system, which it is known increases the α/p_0 values. Although the presence of an impurity, as shown above, becomes more marked as E/p_0 decreases, the experimental means of obtaining these lower E/p_0 values necessitates for any particular system a corresponding use of increased gas pressures. In the case of Masch this pressure increase was exceptional, as he used a 6-mm. maximum gap. Thus, at $E/p_0 \simeq 100$, $p_0 \simeq 10$; at $E/p_0 \simeq 50$, $p_0 \simeq 700$ and at $E/p_0 \simeq 30$ a pressure of 2,000 mm. mercury was employed. At these pressures the effect of the presence of mercury should be small to negligible. A sharp break in the results of Posin[5] at $E/p_0 = 54$ at which the pressure employed was increased from 1 to 100 mm. mercury can also be attributed to the reduced effect of mercury contamination in the lower E/p_0 region. To check his gas samples Masch tested nitrogen obtained from sodium azide (as for Harrison's (*a*) curve) and could detect no difference.

Results obtained by N. J. Peacock (private communication) for 99·9 per cent cylinder nitrogen in a system with which excellent agreement was obtained for 99·95 per cent hydrogen[9], also agree with Masch's values and coincide with the present results. This agreement is important, as it enables α values obtained in necessarily large systems as a preliminary to the investigation of secondary processes to be used with confidence.

Thanks are due to Prof. M. W. Humphrey Davies for facilities provided. This work was carried out during the tenure of an Imperial Chemical Industries Fellowship, which is gratefully acknowledged.

Rise and Decay of Intensity of Luminescence of Short-Persistence Phosphors

RECTANGULAR-WAVE cathodo-excitation of short-persistence phosphors is known[1] to produce curves of intensity of luminescence of the shape indicated in Fig. 1, the sections of rise and decay each being represented by the sum of two characteristic exponential functions. These may be expressed, with the notation of Fig. 1, for the rise by:

$$L_r/L_e = 1 - [k_{r_1} \exp(-t/\tau_{r_1}) + k_{r_2} \exp(-t/\tau_{r_2})] \quad (1)$$

and for the decay, provided that the steady-state condition L_e has virtually been attained at $t < t_p$, by:

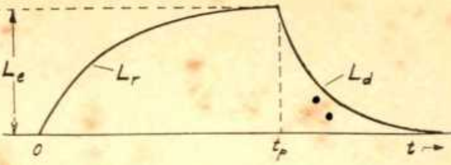

Fig. 1. Pulse of luminescence of short duration with rectangular-wave excitation

$$L_d/L_e = k_{d_1} \exp[-(t-t_p)/\tau_{d_1}] + k_{d_2} \exp[-(t-t_p)/\tau_{d_2}] \quad (2)$$

where $k_{r_1} + k_{r_2} = k_{d_1} + k_{d_2} = 1$, and $\tau_{r_2} \ll \tau_{r_1}$, $\tau_{d_2} \ll \tau_{d_1}$.

The short-period rise and decay of intensity of luminescence in phosphors of the respective types are commonly explained in terms of the random time an electron of a luminescence centre spends in an excited state. So far, no explanation appears to be available for the co-existence of the two exponential processes, with $\tau_2 \ll \tau_1$, during rise and decay.

The phenomenon that $\tau_2 \ll \tau_1$ may possibly be interpreted as the effect of a difference in the structures of luminescence centres, depending on whether they are situated in the body of a phosphor crystal or at, or near, its surface, and resulting in a considerable difference in the respective average time which an electron spends in an excited state. Measurements with phosphors of different crystal-sizes are to be made in order to clarify this question.

The rise and decay characteristics of the intensity of luminescence of the following short-persistence cathode-ray tube phosphors have been determined:

Phosphor *A*: ZnS: 0·005 per cent Ag
Phosphor *B*: ZnS: 0·005 per cent Ag: 0·0005 per cent Ni
Phosphor *C*: ZnS: 36 per cent CdS: 0·017 per cent Ag

(The phosphors were supplied by Derby Luminescents, Ltd.) Their spectral emission characteristics have the usual bell-shaped form with the peak at $\lambda = 0{\cdot}46\mu$ for phosphors *A* and *B*, and at $\lambda = 0{\cdot}525\mu$ for *C*. The phosphors were laid as screens in aluminized cathode-ray tubes of the flash-tube type[2], which were operated at an accelerator voltage of 15 kV. with rectangular-wave beam-current pulses of 30 μsec. duration at a frequency of 50 pulses/sec., the whole screen area of a tube being excited simultaneously and at a uniform density. The variations of intensity of luminescence were picked up with an electron-multiplier photovalve responding to radiation with $0{\cdot}30\mu < \lambda < 0{\cdot}65\mu$, and recorded with a high-speed recurrent-transient oscillograph.

The measurements were made for different values of electron beam density, J_b, and with the spectral response of the photovalve (*a*) corrected to that of the photometric standard observer for photopic vision, that is, eye correction, and (*b*) modified with a Chance *OX*7 filter so that the photovalve responded only to any ultra-violet radiation with $0{\cdot}30\mu < \lambda < 0{\cdot}43\mu$ transmitted through the cathode-ray tube face. The results are given in Table 1, the coefficients k and time constants τ relating to equations 1 and 2. The values of k_{r_1} and k_{r_2}, and of τ_{r_2} (see equation 1) are not given in Table 1, because they could not be determined accurately due to the fact that the beginnings of the rising curves were not accurately recorded with the existing equipment.

The results in Table 1 confirm[1] that $\tau_{d_2} \ll \tau_{d_1}$, and that increasing J_b tends to reduce the values of τ_{d_1} and τ_{d_2}. In addition, it is to be noted that (*a*) in all cases we have $\tau_{d_1} < \tau_{r_1}$, and (*b*) the values of τ

Table 1

Phosphor	J_b (m.amp./cm.^{2})	Visible radiation					Ultra-violet radiation				
		τ_{r_1} (μsec.)	kd_1	τd_1 (μsec.)	kd_2	τd_2 (μsec.)	τ_{r_1} (μsec.)	kd_1	τd_1 (μsec.)	kd_2	τd_2 (μsec.)
A	8·0	10·0	0·80	4·8	0·20	0·4	7·0	0·80	4·2	0·20	0·2
	2·0	11·2	0·80	7·0	0·20	0·5	10·0	0·80	5·2	0·20	0·2
B	5·0	8·5	0·88	5·5	0·12	1·0	4·5	0·80	4·0	0·20	0·4
	1·25	11·5	0·88	7·0	0·12	1·1	10·0	0·80	4·2	0·20	0·4
C	8·0	6·0	0·80	5·5	0·20	0·3	2·5	0·80	2·0	0·20	0·2
	3·0	10·0	0·80	7·0	0·20	0·5	7·0	0·80	5·5	0·20	0·9

for ultra-violet radiation are smaller than the corresponding values for visible radiation.

The difference in the values of τ for ultra-violet and visible radiations indicates a difference in the average time an electron spends in an excited state. It may perhaps be concluded that the difference depends on the height of the energy-level of the excited state and hence the magnitude of the energy-jump of the electron when returning to the ground-state, a higher energy-level being associated with a shorter average time in the state of excitation, and vice versa. This point is to be investigated in more detail.

The observation that $\tau_d < \tau_r$ contradicts existing theoretical considerations[1], according to which the time constant for rise should be smaller than that for decay.

Take approximations for the luminescence intensity curve (Fig. 1). Then for a rise in luminescence:

$$L_r/L_e = 1 - \exp(-t/\tau_r) \tag{3}$$

and for decay, with L_e independent of t_p,

$$L_d/L_e = [1 - \exp(-t_p/\tau_r)]\exp[-(t-t_p)/\tau_d] \tag{4}$$

The energy, W_r, stored in excited electrons during the rise is, from equation 3 and with a proportionality factor A,

$$\begin{aligned} W_r &= A\int_0^{t_p}(L_e - L_r)\,\mathrm{d}t \\ &= A\,L_e\,\tau_r[1 - \exp(-t_p/\tau_r)] \end{aligned} \tag{5}$$

The energy, W_d, converted from excited electrons to luminescent radiation during decay is, from equation 4:

$$\begin{aligned} W_d &= A\int_{t_p}^{\infty} L_d\,\mathrm{d}t \\ &= A\,L_e\,\tau_d\,[1 - \exp(-t_p/\tau_r)] \end{aligned} \tag{6}$$

From equations 5 and 6:

$$\tau_d/\tau_r = W_d/W_r \tag{7}$$

Because of non-radiative dissipation of energy of excited electrons when returning to the ground-state, we have $W_d < W_r$, and thus from equation 7 that $\tau_d < \tau_r$, which is in accordance with experimental evidence.

The magnitude of the ratio τ_d/τ_r is governed by the magnitude of non-radiative dissipation of energy and is therefore a measure for the probability of non-radiative return of an excited electron to the ground-state.

Estimation of Chain Fracture during the Cross-linking of Rubber Hydrocarbons by High-Energy Radiation

Exposure of hydrocarbon polymer molecules to high-energy radiation results either in a decrease in their molecular weight or intermolecular interaction, with the eventual formation of an insoluble network. The primary factor which determines what happens is the relative incidence of fracture of the main chain of carbon atoms to cross-link formation. The ratio of fractures to cross-links, β, has usually been estimated from studies of the solubility of irradiated polymers. The bulk of such work has been on polyethylenes, and even under comparable experimental conditions widely differing estimates of β have been reported. Measurements of the stress relaxation during irradiation have also been used in an attempt to obtain alternative estimates of the chain fracture during irradiation[1].

One of us has recently developed an analysis which permits the calculation of both degree of cross-linking and the molecular weight of primary molecular chains cross-linked into the network from simple extension stress–strain measurements[2]. This analysis requires the determination of two elastic constants C_1 and λ^*; the value of C_1 depends upon both the frequency of cross-links and the molecular weight of primary molecular chains, while the value of λ^* depends solely on the former.

These three methods have been used to study the fracture of purified natural rubber exposed *in vacuo* to a 4-MeV. electron beam. No quantitative analysis of the solubility data was attempted as it did not conform to the behaviour predicted by Charlesby and Pinner from theoretical considerations[3]. However, the results indicated that there was little consummated chain fracture as the sol fraction tended to less than 0·7 per cent after long periods of irradiation. Approximate values of β of 0·14 and 0·11 were obtained from stress–relaxation and stress–strain measurements respectively. The value of β obtained from stress–strain measurements may prove to be an under-estimate, as it is based on a calibration involving the assumption that no chain fracture occurred in the formation of networks by the thermal decomposition of di-*tert*. butyl peroxide.

An approximate calculation in which it was assumed that: (1) all bonds in polyisoprene have an equal probability of fracture and (2) the fracture of each carbon–hydrogen bond results in the formation of one cross-link gave a value of β of about 0·5. It thus appears probable that chain fracture followed by direct recombination was a frequent reaction. Such a reaction would escape detection by any of the three methods of analysis, although the stress–relaxation method should detect the combination of the ends of fractured chains into the network[4].

These three methods of analysis are now being used to investigate both the effect of additives and the temperature of irradiation on the value of β, and experimental data will be published in the near future.

Samples were irradiated at Wantage Radiation Laboratories (Atomic Energy Research Establishment), and we thank Dr. R. Roberts and members of the Technological Irradiation Group for their kind co-operation.

Etch Pits on Calcite Cleavage Faces

IN a recent communication, Watts[1] describes a number of etch pits found in freshly cleaved calcite, and in particular notes that three, four- and five-sided pits are found, with the first two types having some curved sides. I have also observed similar shapes, and have examined these under a surface-finish interference microscope (C. Baker of Holborn, Ltd.) using a × 40 objective and a mercury vapour lamp with a green filter ($\lambda = 0 \cdot 564\mu$). This type of interferometer compares the surface under investigation with a reference surface in the objective, and shows a magnified image of the surface crossed by fringes. These fringes are straight for a perfectly plane surface, whereas irregularities cause the fringes to be shifted into a pattern that may be likened to a contour map, of vertical spacing $0 \cdot 273\mu$. The number and direction of the fringes in the field may be varied by tilting the specimen.

All the investigations were on calcite plates that had been freshly polished to a high optical standard parallel to a cleavage plane, or parallel to the optical axis. These plates were first examined by various interferometric and optical transmission methods, and only those plates selected for the investigation in which no internal optical irregularities of any kind could be detected.

The surfaces were etched with 10 per cent hydrochloric acid for 10–60 sec., and then washed in distilled water.

Fig. 1*a* shows a cluster of four-sided etch pits in a surface parallel to a cleavage plane. The typical concave nature of the walls is clearly shown by the form of the fringes. A similar etch pit is shown in Fig. 1*b*, but with a single isolated pit in one wall of approximately an eighth of a micron deep. Fig. 1*c* shows a line of overlapping five-sided pits. Several lines of fringe disturbances appear to originate from the vicinity of the pits. It is possible that the line of pits may be due to preferential etching along a dislocation line.

The remaining photographs are of etch pits obtained on surfaces of plates cut parallel to the optical axis of the crystal. In this case, the pits are boat-shaped, as shown in Fig. 1*d*. With longer etching, the ends become more rounded (Fig. 1*e*), but the pits never appear to become circular. If the microscope stage and the specimen are tilted, the fringes can be made to cross a pit, as in Fig. 1*f*, to show its typical rounded bottom.

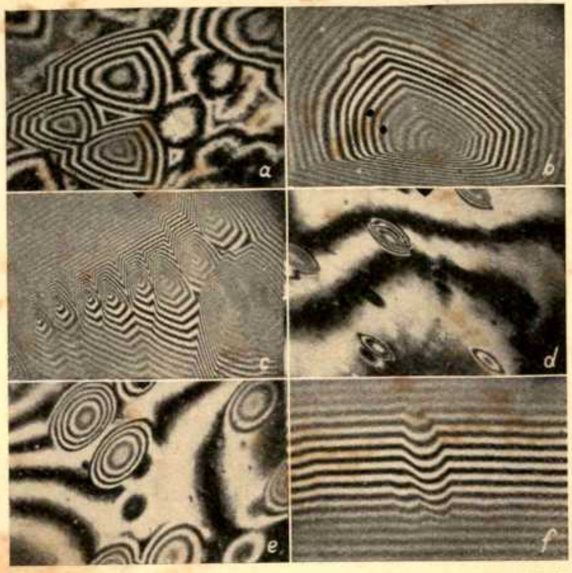

Fig. 1. (*a*) Four-sided etch pits, 20 sec. etching; (*b*) four-sided etch pits, 20 sec. etching, showing isolated hole in curved wall; (*c*) line of overlapping pits, 60 sec. etching; (*d*) boat-shaped etch pits, 10 sec. etching; (*e*) boat-shaped etch pits becoming rounded after 30-sec. etching; (*f*) rounded bottom of boat-shaped etch pit, 10-sec. etching. (× *c*. 40)

It is most noticeable, in these interferograms, how precipitous is the edge of a pit; there appears to be no rounding of the fringes at an edge.

I am indebted to the directors of C. Baker, Ltd., at whose works these photographs were obtained.

Origin of Libyan Desert Silica-Glass

SINCE first reading of Libyan Desert glass[1], I have been intrigued concerning its origin. In the course of investigation of impurities in the glassy state, the role of trace germanium in fused silica was studied[2,3]. All fused silica produced artificially from natural quartz contains trace germanium impurity. Two different fused silicas investigated contained 0·9 p.p.m. of germanium[3]. It occurred to me that the trace germanium content of Libyan Desert glass might offer a clue to its origin, as no trace germanium would be expected to volatilize selectively (as germanium(II) oxide) during sudden melting and quenching of a high silica-content glass.

Table 1 gives the results of trace analyses of germanium, using a modified method of Schneider and Sandell[4], in Libyan Desert silica-glass, Libyan Desert sandstone, a Libyan Desert quartzite, two Libyan Desert sands, Aouelloul crater 'impactite' glass, two obsidians, the average for tektites from eleven different localities, including all known sources except Billiton (Darwin glass and americanites excluded), and the range for the non-magnetic portions of six meteoritic stones. It is seen that the Libyan Desert silica-glass contains very nearly the same germanium content as Libyan Desert sands. The average germanium content of the four materials from the Libyan Desert (other than glass) is 0·77 p.p.m. This agrees very closely with the value 0·80 for the Libyan Desert silica-glass and is not too different from the value for impact glass from the

Table 1. Spectrophotometric Analyses of Trace Germanium in Silicates

Silicate	Source	Ge content (p.p.m.)
Libyan Desert silica-glass	25° 2′–26° 13′ N. 25° 24′–25° 55′ E.	0·80
Libyan Desert sandstone	Gebel Qatrani District, north El Fayum, approx. 29° N. 31° E.	0·52
Libyan Desert quartzite	Gebel Qatrani district, north El Fayum, approx. 29° N. 31° E.	0·95
Libyan Desert sand	Gebel Qatrani District north El Fayum, approx. 29° N. 31° E.	0·77
Libyan Desert sand	From dune 50 km. north of Ghat, Libya, approx. 25° N. 10° E.	0·85
Aouelloul Crater glass Impactite	20° 15′ N. 12° 41′ W.	0·64
Obsidian	Lipari, Ægean Sea	1·67
Obsidian	Iceland	1·68
Average for tektites from eleven localities		0·23 ± 0·13
Range of non-magnetic portion of six meteoritic stones		0·09 – 3·02

Aouelloul crater. Obsidian, in general, has about twice the germanium content of the Libyan glass. Tektites, with which Libyan Desert silica-glass is sometimes classified, all have lower germanium contents than the latter. However, stony meteorites bracket the value of 0·80.

In Table 2 an analysis of the Libyan glass is compared with that of Aouelloul glass and sandstone, as well as an Ivory Coast tektite. It is seen that its trace elements match the sandstone more closely than even the impact glass and is quite different from the tektite. According to the results of Friedman[6], the Libyan Desert glass contains an order of magnitude higher water than any tektite and three times as much water as the Aouelloul glass. The latter difference may be correlated with the higher silica content of the Libyan glass.

The dark areas in Libyan Desert silica-glass were found by absorption spectral measurements to be due to streaks of ferrous iron. The inhomogeneity, the presence of crystallites, and the streakiness of the ferrous-containing regions indicate that the glass remained molten for only a short time.

I conclude from the chemical and mineralogical content that Libyan Desert silica-glass is terrestrial in origin, being formed from Libyan Desert materials, most likely by impact of some cosmic body. In this regard the area around 22° 18′ N. and 25° 30′ E., containing explosion craters (as well as volcanic evidence)[9], should be more thoroughly investigated. Ehmann and Kohman[10] indicate a cosmic origin for Libyan Desert silica-glass based on the apparent presence of aluminium-26 and beryllium-10. However, the level of activity of aluminium-26, for which the measurement was the more reliable, is lower than that in chondrites and in australite, and may be due to some other cause than free-space cosmic radiation.

Table 2. Analyses

Element (oxide)	Libyan Desert silica-glass*	Aouelloul: Sandstone‡	Aouelloul: Glass‡	Ivory Coast tektite§

Diurnal Lapse of Signals from *Sputnik III*

The radio signals from Satellite 1958 δ 2 have been observed consistently on close transits at Blaxland, near Sydney, in Australia, since shortly after its projection into orbit in May 1958. Until recently no definite failure of signal was observed, although the pulsed modulation code has at times been erratic.

Since early in March, however, there have been definite lapses of modulation. Systematic observation with equipment previously described[1] has established that the modulation is now present only when the satellite is actually in sunlight and ceases soon after it enters the Earth's shadow. This can lead to confusion in casual observations as the transmission may be detectable for only part of a transit. In a particular transit it may actually be received by an indirect propagation path when the satellite is approaching or receding, but not during the closest part of that transit when direct transmission would be expected.

An interesting feature is that, on very close transits, in the absence of the pulse modulation, a weak continuous-wave signal can still be detected with sufficient strength to record the Doppler shift. The rate of Doppler shift definitely establishes the signal as transmission from the satellite. It can thus be very useful for radio tracking in the absence of modulation. This continuous radiation is audible, and visible on the records, as a background when the modulation is present, as can be seen in the diagram in the communication mentioned. The reason for this background radiation would no doubt be apparent if we had a little information on the emitting equipment.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Tuesday, June 2

Bone and Tooth Society (at the Institute of Orthopædics, 234 Great Portland Street, London, W.1), at 2.55 p.m.—Annual General Meeting, followed by Scientific Papers.

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Prof. C. M. Robertson: "Animals in Ancient Greece".* (Fifth of six lectures on "Animals in Archæology". Further lecture on June 9.)

Wednesday, June 3

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. D. Stafford-Clark: "The Contribution of Psychiatry to Modern Medicine".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. N. Rast and Mr. R. V. Beavon: "The Nomenclature and Diagnostic Characters of Ignimbrites, with reference to Snowdonia"; Dr. D. S. Weedon: "The Gars-bheinn Sill, Isle of Skye".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. C. F. Powell, F.R.S.: "The Origin of Particles of Great Energy in the Cosmic Radiation".

Thursday, June 4

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. D. M. S. Watson, F.R.S.: "The Myotomes of Acanthodians"; Mr. G. R. Coope: "A Late Pleistocene Insect Fauna from Chelford, Cheshire".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Mr. W. B. Fagg: "A Field Report on Yoruba Art".

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Some Polarographic Problems Encountered in a Private Consulting Practice" introduced by Mr. F. Kenyon.

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Assistant Lecturer (with a science degree, with special qualifications and preferably postgraduate experience in entomology or helminthology) in Zoology—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (June 5).

Laboratory Steward (over 21 years of age, with previous laboratory experience, and preferably experience in the preparation of biological materials and in photography) in the Department of Botany—The Registrar, University College, Singleton Park, Swansea (June 6).

Lecturer (with research experience in pure mathematics) in Mathematics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (June 6).

Principal (with high academic qualifications and teaching and organizing experience in a university department, grammar school or technical college) of Croydon Technical College—Chief Education Officer, Education Office, Katharine Street, Croydon (June 6).

Senior Lecturer (with a degree in chemistry or pharmacy and a postgraduate qualification) in the Pharmacy Department, to direct research and to undertake a limited amount of postgraduate teaching—The Registrar, The Technical College, Sunderland, Co. Durham (June 6).

Research Fellow (with a Ph.D. degree or equivalent research experience in physical-organic chemistry or biochemistry) in the Chemistry Department, for an investigation of the mode of action of germicides—The Professor of Chemistry, The University, Hull (June 8).

Research Fellow (with a Ph.D. degree or equivalent research experience) in the Chemistry Department, for work on adsorption from the liquid phase by carbon adsorbents, in collaboration with Dr. J. J. Kipling—The Professor of Chemistry, The University, Hull (June 8).

Lecturer (graduate in either physics or engineering) in the Department of Physics, either to develop electronic instruments for application in nuclear physics or to undertake development work on the Department's synchro-cyclotron or other accelerating machines—The Registrar, The University, Liverpool (June 10).

Lecturer (with qualifications in genetics, preferably with emphasis on animal genetics) in Animal Genetics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (June 10).

Senior Lecturer in the Department of Anatomy, to be primarily responsible for the organization and teaching of anatomy in courses for postgraduate students—The Secretary, The University, Edinburgh (June 10).

Junior Lecturer (preferably with medical qualifications) in Physiology—The Secretary, Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (June 12).

Lecturer in Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (June 13).

Assistant Lecturer in Philosophy—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (June 15).

Lecturer or an Assistant Lecturer in the Department of Physics—The Deputy Registrar, The University, Birmingham 15 (June 16).

Geologist (with an honours degree in geology) at the New Zealand Oceanographic Institute of the Department of Scientific and Industrial Research, Wellington, for research in problems of marine geology and particularly those of sedimentation—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. B.11/21/8 and mentioning *Nature* (June 17).

Lecturer in Chemistry, a Lecturer in Geology, a Lecturer (with a good honours degree in electrical engineering or physics, and preferably research experience in solid-state electronics) in Electrical Engineering, a Lecturer in Mathematics, a Lecturer in Psychology, an Assistant in Physical or Inorganic Chemistry, and an Assistant in Biochemistry at Queen's College, Dundee—Joint Clerk to the University Court, The University, St. Andrews (June 17).

Assistant Lecturers in Botany (2), Chemistry, and Psychology—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (June 19).

Assistant Lecturer in Physics—The Registrar, The University, Manchester 13 (June 20).

Lecturer (preferably with a knowledge of the theory and practice of mechanisms and automatic controls) in the Postgraduate Department of Applied Mechanics—The Registrar, The University, Sheffield (June 20).

Demonstrator (Assistant Lecturer) in Physiology—The Registrar, The University, Leeds 2 (June 22).

Chair of Theoretical Physics in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (June 27).

Demonstrator in the Department of Organic Chemistry—The Registrar, The University, Leeds 2 (June 30).

Head of the Department of Pure and Applied Physics—The Registrar, Royal Technical College, Salford 5, Lancs (July 1).

Senior Lecturer for postgraduate teaching in the Department of Pathology—The Secretary, The University, Edinburgh (July 1).

Lecturer in Psychology at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 6).

Senior Lecturer in Organic Chemistry at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (July 31).

Assistant Lecturer (with an honours degree and interested in research work) in the Biology Section of the School of Pharmacy—The Secretary-Treasurer, Royal College of Science and Technology, George Street, Glasgow.

Biometrician (graduate in mathematics with an interest in biology) in the Section of Statistics, for duties involving consultation and research on the design and analysis of experiments—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 59/7.

Research Assistant (with a degree or diploma in agriculture or allied subjects with some interest in grassland), for work in connexion with grassland, with some lecturing duties—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon.

Senior Geologist (preferably with a Ph.D. degree in geology and experienced in subsurface stratigraphy, and an interest in economic geology) in the Research Section of the Petroleum and Natural Gas Branch of the Department of Mineral Resources, Regina, Saskatchewan—The Agent-General for Saskatchewan, 19 Chester Mews, London, S.W.1.

Senior Physics Master—The Rector, Glasgow Academy, Glasgow, W.2.

The Unicam S.150 High Temperature Powder Camera makes possible the study of material by X-ray diffraction photography at all temperatures up to 1400°C.

The camera is suitable for capillary or fibre specimens rotated as for normal Debye-Scherrer cameras, and for small block specimens, which may be scanned vertically and oscillated for glancing-angle and back-reflection photographs.

The instrument is fully described in an illustrated brochure, which will be sent free of charge on request.

ACADEMIC FREEDOM AND THE UNIVERSITIES OF SOUTH AFRICA

IT was taken for granted by the working party on higher education in East Africa, which recently formulated recommendations for the re-organization and extension of the Royal Technical College of East Africa, that it—as well as Makerere College and the University of East Africa, to be created eventually—would be multi-racial institutions as an indispensable element of their fully liberal nature and outlook. The University College of Rhodesia and Nyasaland has already been established as an inter-racial institution; although the two groups of students there live in different hostels, they mix without distinction in their academic work, in sport, and socially. This separation has indeed been challenged in Parliament in Great Britain, but the challenge brought not merely the desired reassurance but also evidence of a clear understanding of the nature of a university and deep respect for its autonomy.

These are vital factors if a young university institution is to establish conditions which will attract both Europeans and Africans, and enable them so to work together that the several races may make their full contribution to the development and welfare of the community. Already it is apparent that neither in Africa nor elsewhere is nationalism—or racialism—enough, and that if mankind is to gain control over events there must be the fullest possible contact of trained minds. The responsibilities which rest upon these young university institutions—and indirectly on the universities in Great Britain which have accepted special sponsoring relationships—are indeed heavy, and would tax all the experience of a mature university, with long and high traditions and an accepted place and wide influence in the community.

Even without the acute and inter-related problems of an adequate flow of students of high standard, sufficient well-trained teachers, facilities and opportunities for research, and appropriate relations with the community, including the support which professional associations are often able to give in Britain, it would not be easy for the university institutions which have developed overseas during the past fifteen years to meet the demands made on them for leadership. How much depends on the quality of leadership in the territories now achieving or verging on independence can scarcely be over-emphasized. But it is also true that the quality of the leaders forthcoming from the Colonial and overseas universities depends just as much as it does in Britain and the Dominions on the maintenance of the tradition of university autonomy, on the power of the universities to decide for themselves what students they shall admit, to select their own staff, to choose their fields of inquiry and to serve the community in such ways that their own experience and judgment indicate as best consonant with the work—in short on the tradition and ideals and the resources of a university.

The vital importance to-day of the contribution which the universities can make to leadership in society brings this question of academic freedom into the forefront. A university can only make its proper contribution to national life when it is assured of freedom to teach, to investigate, to discuss and to criticize. Deprived of any one of these, the quality of its intellectual life will decline, creative work may be stifled, research discouraged or discontinued, and ultimately the quality of its teaching sink to that of the school class-room. Amid the almost universal call for more scientists and technologists, for men and women capable of exercising responsibility and leadership in all walks of life, for handling with wisdom and vision the complex technical and human issues in an age of rapid technological change, and the unceasing discussion of how best such men and women can be found and trained, there is sometimes danger of the fundamental conditions which determine the quality of their training being overlooked.

Although there is impressive evidence from the past generation of the damage which is done to a country's real interests and to the character of its leadership by failure to respect the autonomy of its universities, the lesson does not appear as yet to have been fully learnt everywhere. That is a main reason why the whole academic world has followed with profound interest and concern the passage of the Separate University Education Bill, which on April 30 had its third reading in the South African House of Assembly. The Bill, which has been strenuously contested throughout by all the Opposition groups, has now only to go through the Senate before becoming law.

It is sufficient here to point out that the Bill provides for the creation of a series of colleges of higher education for the different Bantu peoples in South Africa, and separately for the Cape coloured people and Indians, but also prohibits the entry of non-white students to the present multi-racial universities of Cape Town and the Witwatersrand; it also removes from the University of Natal the powers it at present explicitly possesses of determining in what place a student is to receive instruction. The background was reviewed in *Nature* early in 1957 (179, 745; 1957), but since then the Committee on Science and Freedom has devoted two successive issues of its *Bulletin* to this question, the second of which (February 1958) reported very fully the impressive meeting on *apartheid* and the world's universities held in London in November 1957 (cf. *Nature*, 180, 1163; 1957). The Council of the University of the Witwatersrand also published papers relating to an interview regarding the Bill with the Minister of Education, Arts and Science in April 1957*.

These papers are still worthy of note for the dignity with which the Council of the University of the Witwatersrand affirms its opposition in principle to legislative enforcement of academic segregation on racial grounds, and deplores the interference of the Bill with the autonomy of the independent university institutions. Noting with deep regret the failure of the Government to consult any of the university institutions concerned in these matters, the Council affirms its conviction that although the university colleges for non-whites as proposed in the Bill may be able to provide instruction for the purposes of the examinations of the University of South Africa, these institutions cannot provide the equivalent of the university education which is available to non-whites at the open universities, and that the establishment of these institutions does not justify the Government in prohibiting the University of the Witwatersrand from continuing to accept non-white students. The provisions of the Bill are accordingly regarded as not merely repugnant to the tradition of universities, but also as specially repugnant to the South African university tradition, which does not admit the idea that the whole of a university staff should be subject to appointment by a Minister and that they should be controlled in all their university activities by Ministerial regulations and by a statutory code of discipline which stifles the academic conscience.

The meeting in London in November 1957 left no possible doubt as to the strong support which is forthcoming among the universities of the world for the South African universities in their protests against the Bill, or the extent to which their belief that the Bill will be grievously injurious to university education in South Africa; and their alarm as to the implications of the Bill are shared. In commenting on that meeting, however, *Science and Freedom* points out that, while Prof. L. J. du Plessis, of Potchefstroom University, gave convincing proof by his personal views and bearing that there are people in the Afrikaans-speaking universities of South Africa who sincerely believe that the development of the natives will best be fostered in their own segregated communities and in universities specially established to serve them on a tribal basis, he failed completely to convince the meeting that the Government of South Africa is equally sincere in this purpose, and that it is not primarily concerned to perpetuate the supremacy of the white race in South Africa. Concern as to possible effects if non-whites, by entering the universities and other cultural centres, should become competent to enter leading positions in the State continually frustrates positive elements in the Government policy; and there appears to be no room for consideration of the nature of a university and how it exerts its influence in society.

The openly expressed view of the Council of the University of the Witwatersrand that unless the Bill is withdrawn no independent university can in the future feel secure from Government interference with its academic freedom is further supported by the correspondence quoted in the papers referred to earlier. They record an attempt by the Minister of Education, Arts and Science to misrepresent in Parliament the University's attitude, which of itself would arouse grave suspicion as to the honesty of the Government's purpose. So far from attempting to explain to Parliament the nature of the university tradition and the dependence of the vitality of a university upon the freedom of teaching, of investigation, of discussion, and of administration that have long been accorded to such institutions in the civilized world, the Minister distorted what was said by the Chancellor of the University, and when challenged tried to gloss over the matter as of no significance. Nowhere in the long reply printed in these papers does the Minister show the slightest understanding of the argument put forward by the University, or of the extent to which its views as to the nature of a university and the conditions for its effective work are shared throughout the universities of the Commonwealth and the free world.

Nor are the authorities in universities of South Africa alone in protesting against the Bill. The National Union of South African Students has been no less active, and is convinced that the issues under test in South Africa are of more than local significance. It believes that the immunity of a university from State direction is one of the most necessary and valuable of our common heritages, the worth of which has been attested in many countries and many ages, and that the State should exercise its power to guarantee this right to a university and the right of all students to choose where they will be educated, not abuse it by enforcing conformity to its political doctrines.

An 'open letter' on the threat to the South African universities sent out by the National Union of South African Students in June 1958 explained clearly the doctrine of *apartheid* and the three measures (the other two are the Fort Hare University College Transfer Bill and the Durban Medical School Transfer Bill) which are designed to force this policy on the universities. The implications of these measures for academic freedom are indicated, and the letter points out that, although the Commission appointed at the last session of the South African Parliament to consider the details of the Separate University Education Bill was prevented from discussing the principle of the Bill, the evidence heard was almost unanimous in its condemnation of the main sections of the Bill. The letter admits, however, that it is unlikely that the Commission will make any recommendation which has not received the prior approval of the Cabinet; it was sent out in the hope of arousing interest, particularly from university men and women, but also from all who cherish the integrity of learning and the aspiration of youth to develop its talents freely and creatively.

* University of the Witwatersrand, Johannesburg. Papers relating to the interview between the University Council's Deputation and the Hon. the Minister of Education, Arts and Science on 1st April, 1957, on the matter of the Separate University Education Bill. Pp. 1+12. (Johannesburg: University of the Witwatersrand, 1957.)

Another message, from the International Committee on Science and Freedom, was published in the *Cape Times* and the *Cape Argus* on January 29, 1959. This Committee, which represents members of 296 universities in 52 countries, condemns in this statement the policy as striking at the roots of genuine university education and menacing the standing of South African universities as members of the world community of learning, and calls on the South African Government to take heed of the disastrous consequences of its policy and to abstain from its further pursuit. Both statements direct attention to the way in which the Government sees fit to ignore informed and responsible criticism, and the ill consequences to South Africa which may well follow if it comes to be regarded as a country which does not recognize the university autonomy common to the rest of the free world.

These newspaper comments show that the Government of South Africa, despite its denial of the opportunity of consultation to the universities, its refusal to meet and examine argument and the very dubious measures to which the Minister has stooped, has not been able to conceal the extent of the opposition to the Bill and the misgivings with which it is regarded. So late as April 16, a protest meeting was held in the Great Hall of the University of the Witwatersrand in Johannesburg, in which the principle at stake was once again emphatically affirmed: "We affirm in the name of the University of Witwatersrand that it is our duty to uphold the principle that a university is a place where men and women without regard to race and colour are welcome to join in the acquisition and advancement of knowledge and continue faithfully to defend this ideal against all who have sought by legislative enactment to curtail the autonomy of the university".

The meeting did not, however, limit itself to the reaffirmation of a principle: "Now therefore we dedicate ourselves to the maintenance of this ideal and to the restoration of the autonomy of our university". The affirmation is one required continually of every member of a university, be he a member of the academic or administrative staff, or student, and the service of the ideal of the free university calls for a like dedication. To the extent that it is publicly made in the universities of the Commonwealth, the members of the universities of South Africa should be encouraged, if not more tangibly supported, as they seek to fulfil their own hard task of restoring the autonomy of their universities. The goodwill in their task which is extended to them by their colleagues in the universities of the world will be reinforced by that of men and women everywhere who recognize that societies need centres of independent thought and criticism for survival, and the dependence of that function upon the guarantee of freedom and the free university. The future of mankind is so bound up with what is happening in Africa that it must still be hoped that the South African Government will reconsider its university policy, which must inevitably destroy its own powers of exercising the wise and humane and inspired leadership that is needed throughout Africa to-day.

EVOLUTION OF GENETIC SYSTEMS

Evolution of Genetic Systems

By Prof. C. D. Darlington. Second edition, revised and enlarged. Pp. x + 265. (Edinburgh and London: Oliver and Boyd, Ltd., 1958.) 21*s*. net.

More than a quarter of a century has passed since, as a young man, C. D. Darlington summarized and synthesized the then recent advances in (nuclear) cytology. The last chapter in this early book (1932) was entitled "The Evolution of Genetic Systems". It dealt with the origin of chromosomes and mitosis, the sexual cycle and meiosis, the spindle mechanisms, the cytology of differentiation, the stabilization of hybridity in apomixis, complex heterozygotes, and polyploids. Seven years later the chapter had grown into a small volume, published separately, in which the author "attempted to show genetics as the study of systems of heredity and variation which rest on the basis of the chromosomes and are related to one another by processes of natural selection". This book belonged to that famous group of evolutionary treatises by Fisher, Haldane, and Dobzhansky which integrated twentieth-century genetics with nineteenth-century evolutionary thought. It assigned to chromosomal cytology, as studied at the level of the light microscope, its place in evolution. This was a brilliant contribution of fundamental significance.

Once more twenty years have passed, and Prof. Darlington offers us a second edition of his work. He feels that genetics, while grown beyond many expectations, "does not seem to have grown beyond the framework I tried to give it". Many of the chapters of the new edition, therefore, are largely unchanged from their original form, although some additions and deletions everywhere show that this is more than a reprint. But there are also new chapters. One, on "The Management of the Cell", introduces all too briefly cytological aspects of development and differentiation such as the chemical hierarchy of deoxyribonucleic acid, ribonucleic acid and protein, and interrelations between nucleus and cytoplasm. Two other new chapters, near the end of the book, are entitled "Types of Plasmagene", and "Heredity and Infection". They "admit a third begetter" of genetics, Pasteur, "whose ideas on microbes and molecules", with those of Darwin and Mendel, "are becoming clearly imprinted on our diagram of nature". In these sections, Darlington discusses our knowledge of extra-nuclear transmission in *Drosophila*, *Culex*, witches' brooms, rogues in peas and tomatoes, and in other cases, and tries to unify it with modern insights into viruses, microbial genetics, and cancer. In a final new chapter on "Initiative in Evolution", the author compares what he calls "the general opinion of Darwinian geneticists" with his own conclusion from the analysis of the evolution of genetic systems. To the others he ascribes the view that natural selection can only produce results which are of immediate utility to the species, while he himself stresses the principle of pre-adaptation in which species acquire an infinite variety of mechanisms which are of no immediate use to them but prepare them for unexpected events. "An automatic property of foresight" is the ingenious label which he applies to this concept.

It cannot be expected that a revision of a book which had an important impact in the 'thirties will do the same in the 'fifties. The earliest insights have long become part of our thinking, either as possessions or as starting points for different views. The newer opinions on plasmagenes, infection, and differentiation seem less unique and more ephemeral. In details, one wonders why a wool-thread model of crossing over is still discussed and only a mention of molecular models of deoxyribonucleic acid and their relation to crossing over, why chromosomes are unreservedly called "molecules of immense size", why there is nowhere a treatment of the recent work on nuclear transplantation and differentiation, why the special X-chromosome–autosome balance in *Drosophila* is made to appear as a general scheme of sex determination, why "the virus" is called "a protein molecule", and why the references to the literature include so many minor items when some of the major ones are omitted. But we should not demand painstaking accuracy and coverage from an author whose merit has been to give us stimulating, if subjective, treatments of the place of cytology in genetics and evolution.

CURT STERN

NEW LIGHT ON OLD DARKNESS

Listening in the Dark

The Acoustic Orientation of Bats and Men. By Prof. Donald R. Griffin. Pp. xviii+413+16 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1958.) 60*s*. net.

IN 1946, when zoologists everywhere were disentangling themselves from war-service jobs and trying to catch up with six years of unread literature, the most exciting discovery was Galambos and Griffin (1941) on "Obstacle Avoidance by Flying Bats". This short paper, though it raised more questions than it answered, carried instant conviction. Here evidently was the solution in principle of a problem which had rankled for 150 years. It only remained to determine in detail how the echo-location system of bats worked with the necessary sensitivity and precision.

This enchanting and enthralling book tells of the events leading to that epoch-making paper in 1941, and of the subsequent eighteen-year effort to answer the questions which it raised. But it tells much more. Dr. Griffin is no narrow specialist. He is that rare combination, a first-class experimenter who is also a first-class naturalist. A lesson implicit throughout the book—and a lesson that zoologists disregard at their peril—is of the degree to which the successful solution of a problem is dependent on the correlation of laboratory experiment with close and well-directed observation in the field.

The book opens with two chapters on the general biology of bats, including sections on their economic and medical importance and on migration and homing. Then there is an account of the genesis of the echo-location problem from Spallanzani's first observation in 1793 that bats, unlike owls, could avoid obstacles in complete darkness and Jurine's demonstration in the following year that this capacity was lost if their ears were blocked, to the suggestion of Hartridge in 1923 that bats emit high-frequency sound which generates a detectable echo.

There follow chapters on the voices of bats and on their hearing, on critical tests of their ability to avoid obstacles, and on the evidence of their catching insects by echo-location. So far the account is based principally on the Vespertilionidæ, which Dr. Griffin has known best and longest. Chapters 8 and 9 deal with echo-location in the long-eared bats, the horse-shoes, the fish-eating bats, the fruit bats and the vampires.

The remaining chapters carry the implications of echo-location beyond the Cheiroptera. There is an account of Dr. Griffin's own demonstration of echo-location by *Steatornis*, the oil-bird of Caripe, and of Schevill's evidence for echo-location by whales. There are instructive comparisons with the navigational devices of electric fish described by Lissmann and with the British inventions of Asdic and R.D.F. (now called sonar and radar respectively in deference partly to American susceptibilities and partly perhaps to euphony). There is a chapter with implications of serious practical importance on echo-location by the blind. Finally, Chapter 15, entitled "The Experimental Naturalist in Modern Science", is a persuasive and beautifully written plea for the preservation of an open mind, a plea which every zoologist should read with self-critical attention.

Although Dr. Griffin freely acknowledges the assistance he has received from physicists, it is clear that he has on occasion been hampered by their *obiter dicta* about what is possible and what is not, as Darwin was hampered by Kelvin's confident and erroneous assertions about the age of the Earth and the time available for evolution. *A propos* the possibility that *Noctilio* echo-locates fish just below a water surface (p. 244), "one physicist has told me that if I should persist in even considering it seriously he would cease to believe anything I ever have to say about bats and their acoustic orientation!" Dr. Griffin was more moved than he need have been by this horrific threat, which must have been based on prejudice and a failure to consider the conditions. A fish possessed of an air-bladder and situated half a wave-length below the surface will 'look like' a hole in that surface to an echo-location system situated above it: and the detection of such a hole would surely not offer any special problem to animals which can find a crevice in a solid wall or avoid a wire 0·25 mm. in diameter.

The index and bibliography seem to be both adequate and accurate. The book is well produced and misprints are very few. The text is also accurate wherever I have been able to check it, though I take exception to the statement on p. 146: "Under favorable conditions experienced human subjects can estimate the angular position of a sound source with an error slightly less than 10°". Under favourable conditions even inexperienced human subjects can do a great deal better than that: and so can cats and dogs and chickens, as Englemann showed long ago.

There is one inconvenient omission. Dr. Griffin, after thirty years of intimacy with bats, has altogether too much confidence in the non-cheiropterist's ability to assimilate and retain the systematic information in the first chapter of the book. There is nowhere to be found a table of bat affinity; and many readers may feel compelled, as I did, to make for themselves one showing the orders and families of bats and the position therein of each genus mentioned in the text, and its geographical distribution. It is to be hoped that future editions will include such a table in a form which allows quick reference.

On its factual content this book is well worth its place (and its not inconsiderable price) on any reference shelf, but content does not fully explain why, once begun, it is so difficult to put down until it is finished. Its grip is only partly due to the fact that it is written in vigorous, grammatical and intelligible English. On reflexion it seems to me that its charm lies in the candour with which Dr. Griffin recalls his expectations at every stage in his long pilgrimage, even when they led him astray, and the frankness with which he records the difficulties, practical and theoretical, administrative and financial, real and imaginary which he has encountered. Because he does not mind admitting his mistakes, one comes to realize that they have been extremely few. But the reader is carried expectantly and more or less effortlessly from crisis to crisis. The virtues of the authoritative treatise have been seamlessly welded to the virtues of the 'Whodunit', and the book can be recommended with confidence not only to the zoologist who must have it, but also to anyone at all with an I.Q. of more than 100 who can afford to buy it or who can beg, borrow or steal it. R. J. PUMPHREY

COSMIC-RAY SHOWERS

Extensive Air Showers

By Dr. William Galbraith. Pp. xvi+211. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 40*s*.; 7.50 dollars.

DR. GALBRAITH'S book on the extensive air showers of the cosmic radiation is a welcome addition to the rather limited number of books which deal with cosmic-ray phenomena. The author, in his preface, states that it is primarily intended for physics students and graduates who wish to find out what has been done in this field of research, and it may also find a more general appeal to workers in other realms of physics. It may be said at once that the book is ideally suited for a research student embarking on a study of some aspect of the cosmic radiation or nuclear physics, but I fear it is to be doubted whether those not directly interested in this limited field will be prepared for the concentration which is needed when reading this book.

In his introduction, the author gives an excellent résumé of the crucial experiments performed since extensive air showers were discovered in 1938 and the development of the theoretical concepts associated with them. The main body of the book contains eight chapters. The first chapter is mainly theoretical and deals with the photon-electron cascade in detail and the nucleon cascade rather more briefly, with a note on the problem of fluctuations. Five further chapters contain accounts of experiments, with the necessary theory interposed, and deal with the lateral density distribution of electrons, the penetrating particles, the density spectrum, longitudinal development and variations in the rates of extensive air showers. The two remaining chapters deal with experiments performed underground and the Čerenkov light produced by air-shower particles.

The impression that is left on reading this book is that here is a subject of such inherent complexity that there has been a definite tendency to set up apparatus and record results, rather than perform planned experiments with definite objectives in view. As a result the subject abounds with experimental results many of which are difficult to analyse in a way which furthers our understanding of extensive air showers. Dr. Galbraith's book will therefore be of the greatest use to future experimenters as he is not only a keen judge of an experiment from a practical point of view but is also able to see whether it leads to a better understanding of the subject. For this reason, Chapters 2–5, which at first sight may seem to be no more than catalogues of experiments, will repay careful reading. In the chapter on the Čerenkov effect we find traces of the enthusiasm for this fascinating subject which led Dr. Galbraith to participate with such success in the early experiments in which Čerenkov light was found to be associated with extensive air showers.

I should have preferred a fuller account of the statistical nature of the arrival of shower particles with a discussion of the Poisson distribution early in the book. The notation used where the Poisson distribution is discussed on p. 98 tends to be confusing, as the symbol m is used for the number of particles crossing a detector while m is used as an abbreviation for metre and in one case the italic m occurs as an unfortunate misprint. In general, the text of the book is very well set out and misprints are rare. Many of the diagrams, however, are small and confusing and some contain information which is not referred to in the text or contain symbols which do not agree with those of the text.

R. M. TENNENT

ADVANCES IN VETERINARY SCIENCE

Advances in Veterinary Science

Vol. 4. Edited by C. A. Brandly and E. L. Jungherr. Pp. xi+414. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 12 dollars.

THIS volume is composed of ten sections each dealing with problems of practical importance to the stock owner and the veterinary surgeon.

Of these sections, the second, which brings us up to date with information on radiation injury, and the eighth, which presents the current picture of the toxicity of insecticides and herbicides to livestock, will be more avidly scrutinized. At a time when civilization itself may seem to be at the mercy of radiation, the very full information and generous bibliography afforded by this volume are of real assistance to all whose duty it may be to plan and organize civil defence schemes.

As the authors wisely observe—"the widest port of entry into human beings of fission products is through animal products, particularly milk", and the role of veterinary science in maintaining a safe food supply in the face of radiation hazards becomes increasingly obvious.

The entry into the field of agricultural and veterinary parasitology of new insecticides, including the chlorinated hydrocarbons and the organic phosphorus compounds, has posed many problems. Knowledge in this new field is necessarily limited, but the chapter on this subject, if short, is none the less valuable and well supported by its references.

Chapters on defence against imported animal diseases, X-ray therapy in veterinary medicine, genetics and disease, and the epizootiology of leptospirosis bring further knowledge to that already marshalled in current veterinary literature and serve to emphasize once again the basis of a rational approach to these subjects.

Infectious diseases of sheep occupy an important chapter in which bacterial, rickettsial, viral and protozoal diseases of both lambs and adults receive full consideration.

Pigs have two chapters devoted to them—one on infectious atrophic rhinitis and one on enzootic virus pneumonia, and Glasser's disease. In view of the somewhat confused state of knowledge and understanding of these diseases, the clarity with which these chapters are written will be highly appreciated by all readers.

The chapter on Jöhne's disease is of paramount importance to British readers; with the anticipated eradication of bovine tuberculosis from Great Britain within the next few years, the problem of Jöhne's disease assumes new prominence. Indeed, it may well be that Jöhne's disease may be the next target of the animal health authorities in Great Britain. The problem of diagnosis of this disease is apparently far from solved, but, piece by piece, evidence on modes of infection is building a picture from a study of which must one day come a rational means of control and maybe eradication.

The contributors to this volume all deserve the highest praise for the quality of their essays; unnecessary diction is in all cases reduced to a minimum and references are unstintingly given.

If illustrations are somewhat regrettably few in number, the reader will appreciate the difficulties involved in copious illustration of the particular subjects covered. The verdict on this recent work must surely be that it appears at a time when the information it gives is urgently needed and that its readers acknowledge with gratitude the magnificent effort made by its distinguished contributors.

H. BURROW

CONTROL FUNDAMENTALS

Handbook of Automation, Computation, and Control

Edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge. Vol. 1: Control Fundamentals. Pp. xx+1006. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 136*s.* net.

THIS is the first of a series of three volumes and is prepared by a staff of 29 contributors from an impressive cross-section of American universities and industrial organizations.

A handbook is expected to contain a body of material which is related by a common theme. The theme of this work is "Control Fundamentals", but this term has clearly been given a more general meaning than is currently ascribed to it in Britain. Only about half the volume is concerned directly with closed-loop control systems and their analysis and synthesis. The rest is devoted to general mathematics, numerical analysis, operations research and information theory.

The principle followed in Section *A* on general mathematics is to present the notation and major ideas and theorems of each subject chosen for treatment. For rigorous proofs the reader is referred to the generous bibliographies at the end of each chapter. The presentation is necessarily concise and applications of the various techniques described are not given. This leads to the obvious danger that the material may be regarded as insufficiently rigorous by the mathematician and insufficiently practical by the control engineer.

Three chapters in Section *A* are devoted to set theory, matrix theory, and Boolean algebra, respectively. Eight chapters are concerned with algebraic, integral, finite difference and differential equations, complex variable theory, conformal mapping, operational methods and Laplace transforms. Finally, two chapters deal with probability theory and statistics, respectively.

Section *B* on numerical analysis is likely to be of increasing interest as the use of digital computers becomes more widespread. Here are described interpolation and curve fitting methods, numerical differentiation and integration, matrix inversion, eigenvalues and eigenvectors and methods of solving differential and partial differential equations. Computer storage requirements and number of operations are given in tabular form for the various techniques.

Section *C* on operations research occupies 129 pages and is a fairly complete description of the methods used in obtaining optimum solutions to problems arising in industrial systems. It forms a useful introduction to the subject for the control engineer.

Information theory and transmission, in Section *D*, occupies 114 pages and contains a full exposition of the main concepts of information theory, prediction, data coding and the design of optimum filters. Useful curves and tables are given for the design of Butterworth–Thomson filters.

Feedback control in Section *E* occupies 427 pages. Here are presented the well-established techniques for the analysis and synthesis of control systems, with many valuable tables and curves. The first two chapters on methodology and fundamentals include tables of typical component equations and lists of analogous elements of electrical, mechanical and hydraulic form together with their transfer functions. The chapter on stability deals exhaustively with the use of the various graphical methods for stability determination. Transient and frequency response determination is described by analytical numerical and graphical methods. Design charts are given for deriving closed-loop transient and frequency responses from open-loop characteristics and a four-place table of sin x/x is provided for use with a numerical method of transient response determination. Feedback system compensation by series and feedback methods is described and tables are provided showing electrical, mechanical, hydraulic and pneumatic compensating networks and their transfer functions.

The chapter on noise deals with its mathematical description and measurement and with the response of linear systems to noisy inputs. Optimum design for stationary random inputs is treated.

In the penultimate chapter methods of non-linear system analysis are described with particular emphasis on the describing function method. Tables of describing functions are given for a large number of amplitude-dependent non-linearities. A surprising omission is the subject of noise in non-linear systems, on which much work has been published in the past few years.

Sampled data systems are rather briefly treated in the last chapter but useful tables are given of output transforms for basic sampled systems.

This handbook, in addition to presenting most of the existing techniques used by control engineers, also presents the mathematical framework on which much future development will depend. It will appeal most to research workers and development engineers in the ever-widening field of automatic control.

P. H. HAMMOND

Transistor Technology

Vol. 3. Edited by F. J. Biondi. (The Bell Telephone Laboratories Series.) Pp. xiii+416. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 94*s*.

DOUBTS were cast in the review of Vol. 1 and 2 of "Transistor Technology"—a review (see *Nature* of January 10, p. 72) written before the third and final volume was available—of the likelihood of the three volumes satisfactorily filling a serious gap left in the coverage of text-books and reference books. The doubts are largely dispelled by Vol. 3, however. It is only little more than half the size of either of the two earlier volumes, but it contains by far the best descriptions yet given of most of the modern techniques for making junctions and triode structures—many of them brilliantly conceived, carefully worked out and adaptable to large-scale production. It should appeal as strongly to newcomers seeking more than a superficial understanding of the techniques as to the more experienced research workers, technologists and teachers (though as yet this part of the subject is apparently little taught).

The book opens with chapters which classify the methods used to control impurity distributions and to form junctions in germanium and silicon, and show how the several ideas based on liquid-phase freezing and on diffusion in the solid can be exploited. The processes which monocrystalline semiconductors undergo in becoming diodes or transistors are next described. Some chemical processes and the making of ohmic contacts apply widely; others are more specialized, for example, jet etching, alloying and diffusion, the last two being treated in the detail warranted by their importance to-day. The last quarter of the book is on other branches of the subject. Some of the methods for measuring the rate of recombination of minority carriers, both in the bulk semiconductor and at the surface, are described; and a basis for designing equipment to measure selected parameters of transistors is analysed, in terms of ease, accuracy and value to the user. A few pages are devoted to reliability, a subject which is gaining importance.

The presentation of all three volumes conforms with the high standard of the series. It is to be hoped that we can look forward to further volumes, at intervals of a few years, keeping us up to date on material preparation and on device design, fabrication and performance.

J. R. TILLMAN

Studies in the Mathematical Theory of Inventory and Production

By Kenneth J. Arrow, Samuel Karlin and Herbert Scarf. (Stanford Mathematical Studies in the Social Sciences, No. 1.) Pp. x+340. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1958.) 70*s*. net.

THIS book consists of a series of interrelated research papers. The results have been obtained during the past three years and are now published as the first volume of the new series of Stanford Mathematical Studies in the Social Sciences. Most of the research was carried out at Stanford University, largely under the auspices of the Office of Naval Research.

The quantitative study of inventory and production is a relatively new branch of applied mathematics; hence about the first fifty pages of the book are taken up with the historical background, the nature and structure of inventory problems, and summaries of the results of succeeding chapters. It is essential for the reader to study this part of the book, in order to grasp the general mathematical concepts which are developed later in special contexts. Part 2 consists of four papers covering the determination of optimal policies in the case of deterministic processes. One relates to production with marginal cost increasing with time, another to production planning with no storage facilities, and a third is concerned with the smoothing of production. Part 3 relates to stochastic processes and includes several papers on various aspects of the Arrow – Harris – Marschak dynamic model, and a paper relating to a hydroelectric model. The last part of the book is concerned not with the determination of optimal policies but with the operating characteristics of given 'simple' policies, and this is realistic in cases where it is impossible or too difficult to determine the optimal policy. There is a very important and interesting chapter on the application of renewal theory, including recent results of L. Takács.

It is only fair for the reviewer to point out that the present work involves advanced mathematics in every paper, and it is not likely to be understood by either managers or operational research workers who have only taken mathematics as a subsidiary subject at a university. It is certain that results of practical significance are implicit at various points throughout the book. But a good deal of sifting and simplification are necessary before the operational research man can find a result which he can take away and use at once.

L. S. GODDARD

Looking and Finding

By Geoffrey Grigson. Pp. 120. (London: Phoenix House, Ltd., 1958.) 9*s*. 6*d*. net.

ALTHOUGH well known as a writer on poetry, art, history and archæology, this is Geoffrey Grigson's first book for young people. The subtitle describes it as a help to "looking and finding and collecting and reading and investigating and much else". This breathless approach is continued throughout the whole of the not extensive text in which young people are advised how to start with maps and charts; how to use books and read them in "skipping and picking and jumping"; how to make discoveries about the houses they live in and what this has to do with inscriptions and phoenixes and salamanders; about yew trees and green men in churchyards; how boys and girls can make maps of their own manors with the fields, mills and ponds, and how to find, in the country, pack-bridges, toll-houses, tithe barns, wells, springs, withy beds, canals and locks, lime-kilns and many footpaths. In addition, young people are advised where to make archæological and palæontological discoveries and how to make use of museums. For those who wish there are also hints about how to make and manage their own art galleries.

Mr. Grigson's object in writing a book of this sort is wholly admirable, and parts of it will appeal considerably to some extraordinary children with somewhat unusual parents. The majority will find its pace too rapid, its frequent change of direction too violent, and its repeated exhortation to go and do something not so inviting as those sections where the author takes time off to show them what they should look for.

T. H. HAWKINS

MICROSEISMIC RESEARCH AT THE NATIONAL INSTITUTE OF OCEANOGRAPHY

By Dr. H. M. IYER and B. J. HINDE

GREAT BRITAIN is a good place for detailed research on microseisms, because the large number of storms with varying speeds and intensity that form in the Atlantic Ocean each year are usually well charted, and wave information is also available. Three important contributions which appear more or less as milestones in the history of the subject have been made from the British side. These are: (*a*) the wave-interference theory of microseism generation[1]; (*b*) the correlation technique for the estimation of composition and direction of propagation of microseisms[2]; (*c*) the design of the electronic-feedback seismograph[3].

Iyer[4], working on seismograph records from Kew Observatory, made a detailed analysis of microseisms associated with a number of Atlantic storms. The direction of approach of the waves at the recording station was estimated using a modified form of Darbyshire's correlation technique. The following were some of the results.

In general, there exists a composite microseismic source in the wake of a moving storm. The microseisms consist of a mixture of Rayleigh and Love waves. The Rayleigh waves form the main part of the information and the Love waves resemble background noise. The ratio of Rayleigh to Love waves resembles the usually accepted signal-to-noise ratio in any similar phenomenon, and appears to be a function of the distance of the generating source. Thus the farther microseisms travel, the smaller this ratio.

In the winter of 1957–58 nearly twenty major 'microseismic storms' were recorded by an experimental east–west component seismograph at the National Institute of Oceanography. Nothing more than visual reading of the records was possible from these single-component data, and the aim has been to have a three-component microseismic station equipped with a rapid data-handling system.

The new microseismic station has now been installed at the National Institute of Oceanography, Wormley, Surrey. It has two sections, the seismographs and the automatic analyser.

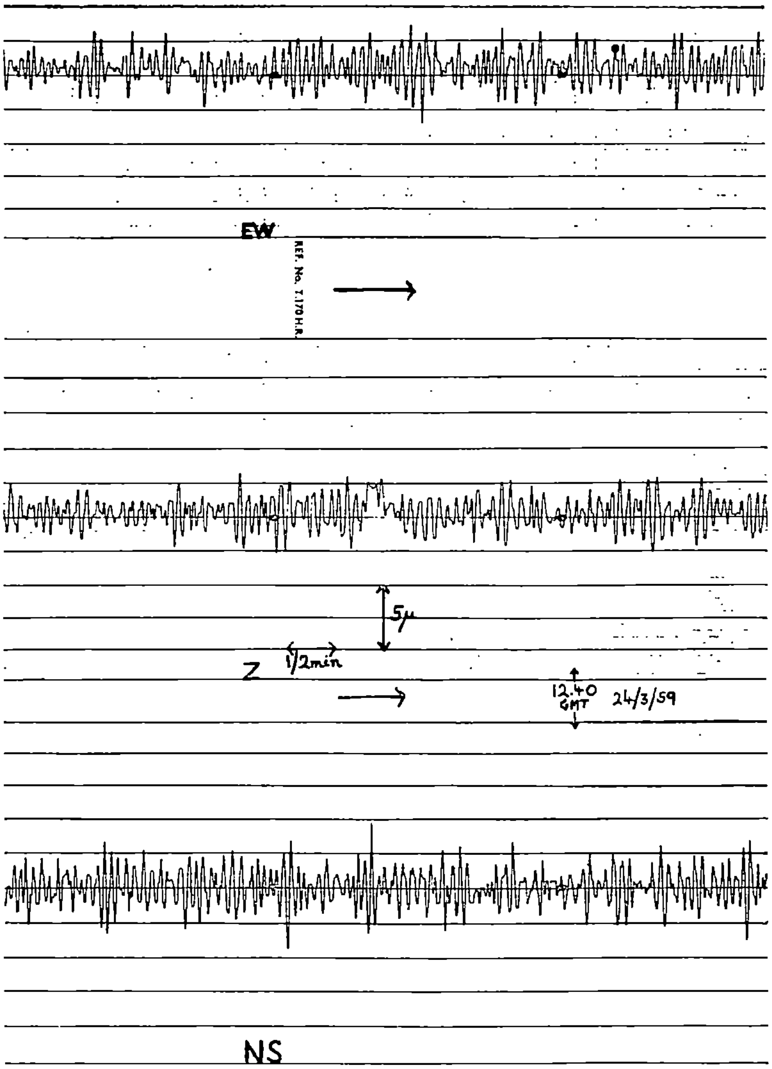

Fig. 1. Sample microseism record taken at the three-component microseismic station of the National Institute of Oceanography

The electronic feedback seismographs developed by Tucker[3] are used at the station. The seismograph has a very high magnification (up to 18,000) and a flat response from 1 to 10 seconds period, a combination of characteristics rarely obtained, though essential for microseismic research. The instrument is mechanically robust and easy to calibrate. In the properly engineered model both east–west and north–south components are incorporated in the same instrument, thus reducing the overall size of the station. The aim is to have a self-levelling system for the seismograph so that it can be buried in a borehole, thus eliminating the need for elaborate and costly seismograph vaults. A vertical-component seismograph employing the same principle has also been designed and is in operation. The instruments

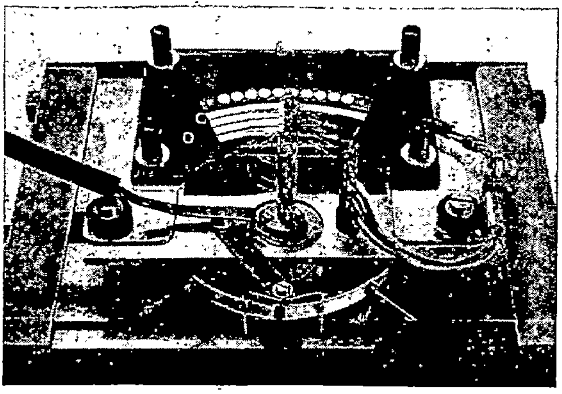

Fig. 2. The contact galvanometer used for directly analysing microseisms from seismographs

are at present accommodated in a brick-lined pit in the lawn, and the proximity of buildings, trees and the railway does not have any spurious effects. The electronics associated with the seismographs and the recorders are kept in the main building and are connected to the pit by cables. Fig. 1 shows a sample record taken on the three-channel recorder.

The information needed from the seismograph signals is root mean square amplitude, period, and the correlation coefficients between the components (for computing composition and direction of propagation). These computations must be made as the information comes through from the seismographs without any appreciable time delay.

The output from each seismograph is fed to a robust moving-coil meter provided with a system of platinized contacts (Fig. 2). The 'dot' or circular contacts are used for measuring root mean square amplitude and the 'strip' contacts for period and correlation measurements.

It is not proposed to explain here the detailed operation of the analyser. It will only be mentioned that the correlation coefficients are calculated by using the meters in two different channels to indicate automatically at regular intervals of time whether the arms are deflected in the same direction or opposite directions. This method has been used with great success by Akamatu[5] and Aki[6] in Japan for the study of short-period microseisms, in conjunction with an electronic computer for the analysis.

Fig. 3 shows schematically the final layout of the microseismic station. The filters can be set to study microseisms of different periods, and this as well as the complete sampling programme is controlled by the time-control circuit. The phase-shift network is used to correct for the phase difference between the horizontal and vertical components of Rayleigh waves in microseisms. For storage of information an automatic camera photographs the counters at the beginning and end of each operation.

Apart from the interest in microseismic study, such a seismic station should be of considerable interest to earthquake seismologists. A three-channel recorder has been provided for continuous recording for the benefit of those interested. The high magnification in the 1 to 10-second region should be of particular interest in earthquake studies.

Fig. 4 shows a sample record of an earthquake (epicentre 71° N., 8° E.) taken on the new seismographs (the three channels were recorded independently and put together). A very interesting pattern of long waves (75 seconds period) was recorded by the experimental east–west component seismograph on

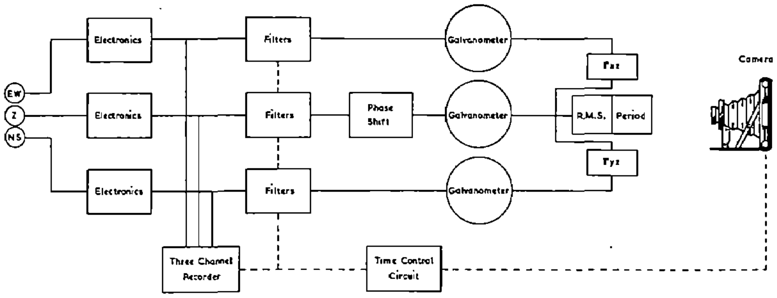

Fig. 3. Schematic diagram of a proposed microseismograph station

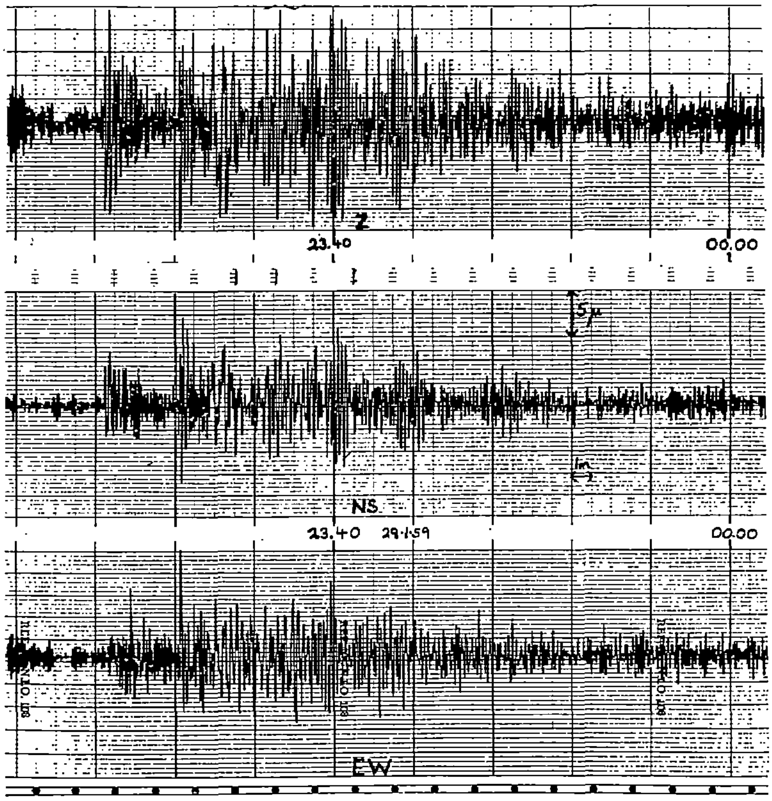

Fig. 4. A sample earthquake record (epicentre 71° N., 8° E.)

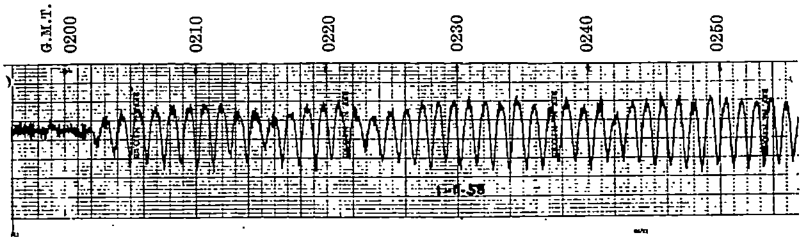

Fig. 5. A peculiar long-period record obtained on the east–west experimental seismograph between 0200 h. and 0250 h. G.M.T. on November 1, 1958

November 1, 1958 (Fig. 5). This could not be attributed to any earthquakes listed in the U.S.C.G.S. epicentre cards.

The system described might form the basis of a simplified storm-warning system in areas where such warnings are still needed. Vast expanses of the Pacific and Indian Oceans are inadequately covered meteorologically, and microseismic stations would be of great value in such areas. It is too early to predict the full utility of the new microseismic station from this point of view, but at least it can be said that it is a simple system with a sound theoretical and practical basis.

INITIATION OF THERMAL REACTIONS BY THE FLASH ILLUMINATION OF ABSORBING BODIES

By Dr. J. L. LUNDBERG and Dr. L. S. NELSON
Bell Telephone Laboratories, Inc., Murray Hill, New Jersey

MINUTE particles, filaments and foils of materials which absorb light have been heated to temperatures as high as several thousand degrees by absorption of a single intense flash of visible light. Heating by flash illumination may be used as a general technique for initiating thermal reactions rapidly, and in comparatively large volumes. The requirements are a high luminous flux falling on an absorbing body immersed in a transparent insulating medium. Using a variety of matrices and absorbers, many thermal processes, such as explosions, pyrolyses and phase changes, have been initiated within the few milliseconds of duration of the flash.

Heating by absorption of continuously emitted visible light has been used for many years[1]. Although Eggert[2] has used intense flashes of light to ignite explosives and oxidize thin aluminium foils, little has been reported on the dependence of thermal effects on the shapes and dimensions of absorbers or the nature of the matrix surrounding them.

Heating by flash illumination of heterogeneous systems first occurred in these Laboratories when samples of commercial polymers were placed, as shown in Fig. 1, along the axis of a spiral quartz discharge lamp (similar to lamp III described by Christie and Porter[3]) and flashed, using 5,000 J. from capacitors charged to 4,000 V. The heterogeneous pyrolysis of the polymers took place around normally occurring particulate impurities, yielding gases, carbon and fluorescent products[4]. Fig. 2 shows polyethylene sheet which had been placed in a borosilicate glass tube and degraded by exposure to one flash. The degradation is essentially independent of the chemical nature of the polymer, since polytetrafluoroethylene, regenerated cellulose, nylon,

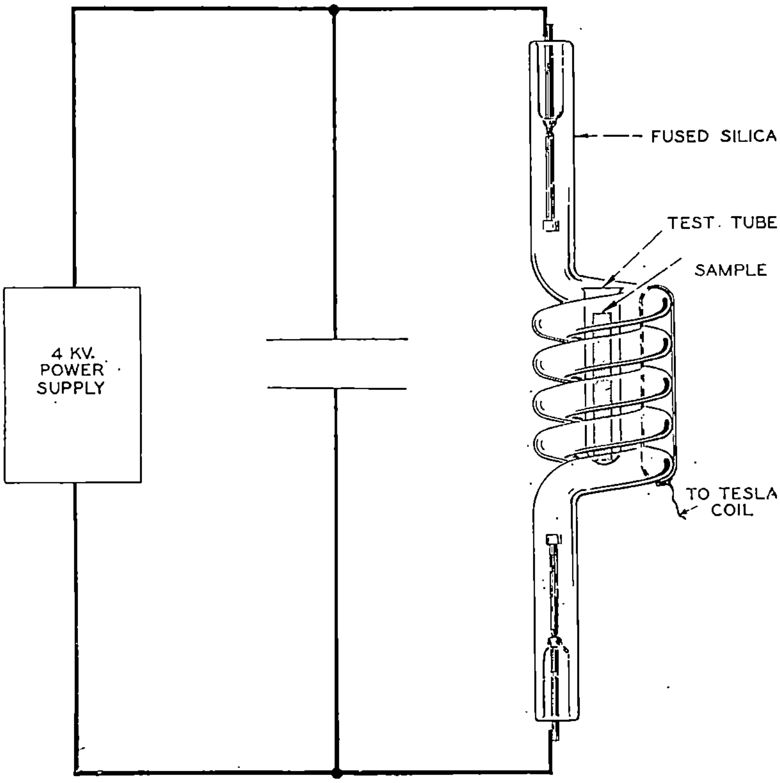

Fig. 1. Experimental arrangement for heterogeneous flash heating

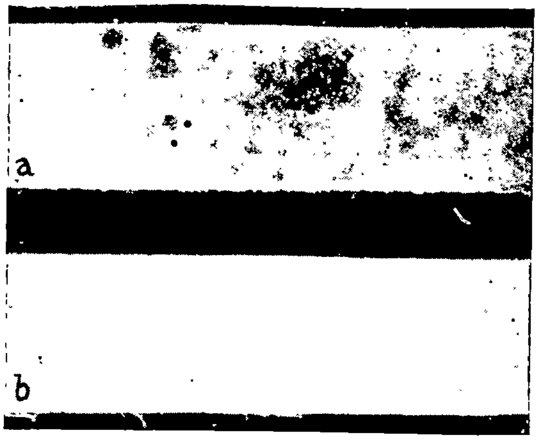

Fig. 2. (*a*) Polyethylene degraded by one flash of 5,000 joules at 4,000 V. (*b*) Control sample

polyethylene, polystyrene and poly*iso*butylene all behave similarly, unless carefully prepared without trapped particulate matter. Clean polymers do not show this type of decomposition in the flash, but can be degraded if absorbing bodies are suspended in them.

If an isolated absorber of small dimensions is irradiated in a transparent matrix, the rise in surface temperature can be estimated from simple heat-balance equations[5]. Fig. 3 shows temperature rises estimated in this way for graphite spheres, cylinders and plates of various radii or thicknesses suspended *in vacuo* or in a liquid hydrocarbon and flashed at half our maximum energy (648 μF., 4 kV., 2·5 msec.). As the radius r of the heated body decreases from large values (1,000μ) the temperature increases, because gradually less energy is used to heat the absorbing body by inward conduction. *In vacuo*, where no outward conduction into the matrix can occur, the surface temperature continues to increase as r decreases until the limit of black-body re-radiation of the incident energy is reached—for these flash conditions at about 4,100° C. for bodies of radius less than 1μ. The validity of this estimate was demonstrated by vaporizing *in vacuo* tungsten and molybdenum as well as carbon of these dimensions almost explosively in a single flash.

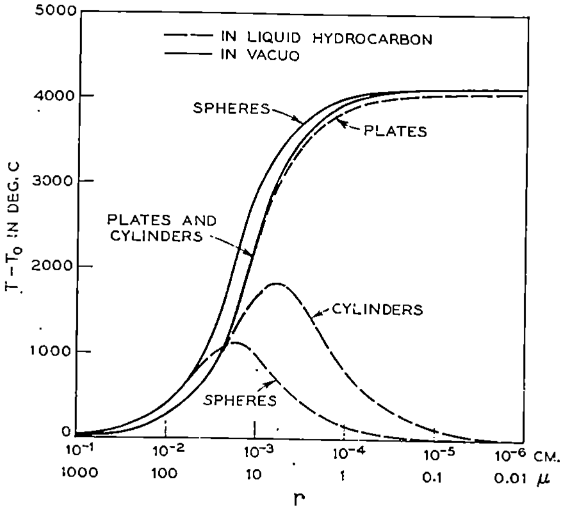

Fig. 3. Rises in temperature estimated for graphite-like absorbing bodies of various sizes exposed to flashes of 2·5 msec., 5,000 joules, 4,000 V.

When spherical or cylindrical absorbers are placed in a condensed transparent matrix such as a liquid or polymeric hydrocarbon, conduction of heat away from the absorbing surface occurs, and the surface temperatures decrease after going through maxima near 10μ. Thus, carbon particles of large diameter (1,000μ) and also carbon black of very small particle size (very much less than 1μ) do not initiate degradation in polyethylene, whereas particles in the size-range 1–100μ cause severe decomposition of the type shown in Fig. 2.

Absorbing foils or platelets, however, should achieve essentially similar surface temperatures in the flash, whether *in vacuo* or in a condensed medium, because heat conduction outward from a foil is not a function of thickness, compared with the strong dependence on radius in the case of spheres or cylinders. Thus, the highest maximum temperatures in condensed matrices should occur with absorbing foils less than 10μ thick.

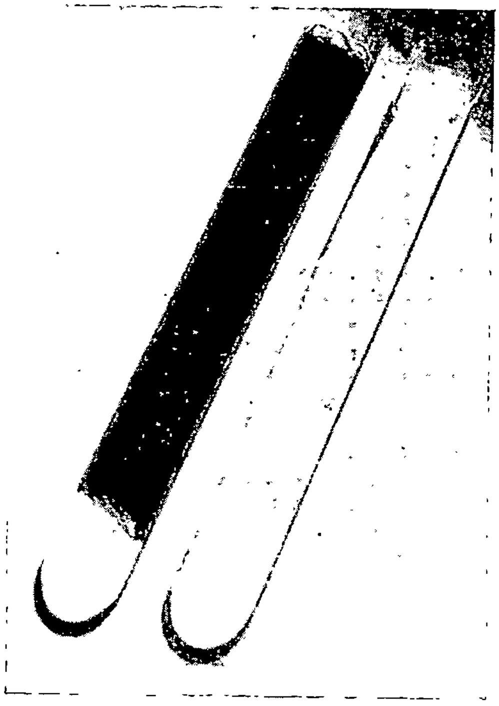

Fig. 4. Mineral oil flashed once at 10,000 joules at 4,000 V. Opaque sample contained 25 metres of 7·5-micron tungsten wire before flashing. Clear sample had no heterogeneous absorber

Because of experimental difficulties, we have never measured temperatures directly, but our experiments seem to be quite well explained by these estimates.

Higher maximum temperatures can probably be obtained by increasing the light intensity either by increasing the energy input to the lamp, or better, by decreasing the duration of the flash. Certainly, the temperature-range of ordinary chemical interest (up to 10,000° C.) seems readily achievable in heating times of 100 microsec. or less by flash heating with relatively modest energy inputs (of the order of 10^4 J.).

Heating by flash illumination has been used[5] to evaporate *in vacuo* powdered silver, carbon, chromium, molybdenum, nickel, tungsten and zinc of particle diameters less than 100μ. When flashed at fairly low intensities, metal foils 5–10μ thick were etched, revealing microstructure of the metal. At higher intensities the foil melted into a small droplet, and at still higher intensities vaporized[6]. Powdered coal has been vaporized and pyrolysed by flashing *in vacuo* and in hydrogen and halogen atmospheres[6].

Flash heating has been used to pyrolyse methane in the presence of 7·5μ tungsten wire; hydrogen, ethane, ethylene, acetylene and carbon were formed[6]. Explosions have been initiated in the systems methane–oxygen and hydrogen–oxygen by flashing these gas mixtures in the presence of borosilicate glass wool. While glass wool is certainly not a simple black-body absorber in triggering these explosions, nevertheless, the glass wool was heated to fusion temperatures[6].

Mineral oil has been flash pyrolysed using suspended molybdenum (less than 74μ) and carbon (less than 36μ) powders, glass wool (8μ) and tungsten wool (7·5μ) as absorbers. Flashing above a threshold energy caused the oil to become black with suspended carbon, effervesce, and fluoresce when excited by 3661-A. radiation. Fig. 4 shows two borosilicate glass tubes of mineral oil flashed once at 10,000 J. The tube with the opaque black suspension contained 25 metres of 7·5-μ tungsten wire, whereas the other had no absorbing material present before flashing. If the solids are filtered from the oil, an absorption spectrum is obtained which is similar to that of an oil degraded in service as a high-voltage insulator.

If a slurry of zinc dust in mineral oil or glycerine is flashed, the metal is evaporated and re-deposited in finer form but without degradation of the matrix. Zinc boils at 907° C.; thus, in the vaporization-redeposition process it must reach a temperature sufficient to pyrolyse the hydrocarbon. Upon flashing zinc dust suspended in polyethylene, zinc was evaporated, but no degradation of the polymer took place. It is possible that the quenching of free radicals by zinc vapour occurs, as in the Paneth mirror removal reaction[7].

Dark particles smaller than 90μ in diameter embedded in polymers become sufficiently hot to cause degradation when flashed above 10^3 J. Carbon, hydrogen, water, carbon monoxide, carbon dioxide, methane, acetylene, ethylene, ethane, and small amounts of higher hydrocarbons are produced when unclean polyethylene is flashed[4,8]. Since the carbon formed with one flash acts as an absorber during the next flash, the amount of degradation in polymers is cumulative with the number of flashes. Empirically, the total amount of gas formed from polyethylene is nearly proportional to the square of the number of flashes[8]. In addition, wax-like degradation products are expelled from the polymer during flashing, and fluorescent materials are deposited near the carbonized centres.

In gaseous or vacuum matrices, absorbing sheets or cylinders, such as wires, fibres or filaments, are the most convenient experimentally since they have known dimensions and shape, are self-supporting, and can be placed in known orientations in the system. Particulate absorbers may be suspended in liquid systems, but for careful work they always show the difficulties associated with agglomeration, poorly known shape, and a distribution of diameters. In very viscous liquids or polymers it is always difficult to incorporate materials without accompanying gas pockets or other disturbances, and reproducibility is never high. In most systems cylindrical absorbers are the most easily handled experimentally.

The experiments described here demonstrate the applicability of rapid heating by flash illumination of absorbers of small dimensions. Further, the similarity of the time-scale and experimental arrangements to the flash photolysis technique[9] suggests its use for preparing free radicals in systems which do not absorb light from the usual flash sources. The chemical effects are somewhat similar to those of shock waves but can be produced in liquid and solid systems as well as gases, to form much greater instantaneous volumes of reaction intermediates. In effect, heating by flash illumination is a heterogeneous sensitization which transfers optical energy from photons unable to cause discrete photochemical processes via thermal excitation into chemical energy, an over-all process quite analogous to true homogeneous sensitization. However, unlike flash photolysis with or without sensitizers, flash heating of absorbing bodies depends little on wave-length of the flash; it often has a threshold intensity below which no discernible reaction occurs, and it has present a hot reactive interface or, in more extreme cases, hot vapour from the absorber, to complicate the reaction.

DARWINISM AND THE STUDY OF SOCIETY

TO mark the centenary of “The Origin of Species”, a conference was arranged at the instigation of the Scottish Branch of the British Sociological Association and held in Adam House, Chambers Street, Edinburgh, during April 8–10. Originally it was envisaged as something of an investigation into the origins and development of Social Darwinism. This intention underwent some change at the hands of the *ad hoc* organizing committee of natural and social scientists from Scottish universities, but the public purpose of the conference emerged as a discussion of the effect of the publication of “The Origin of Species” on social theorizing, and an examination of the present bearing of biology on sociology.

These two main themes became at times closely interwoven, and the core of the conference discussions was, in many ways, Prof. C. H. Waddington's paper on “The Human Evolutionary System”. This was nothing less than an attempt to fit Social Darwinism out in modern dress: to read human history and social development in the light of the biologist's interpretation of evolution.

Waddington began with a concise but extremely lucid exposition of the evolutionary system, under four headings: (1) exploitation, the 'choice' of a particular environmental niche out of the range of possibilities open to any creature, and the possible modification of that environment; (2) epigenesis, the complex and interacting processes by which the development of the fertilized egg into the mature organism is controlled, processes which possess resilience in surmounting obstruction or damage, tend towards the coherent organization of all the single parts, and seek pre-determined end-points of growth; (3) genesis, the transmission of separable hereditary characteristics actually or potentially present in the parents; (4) natural selection, the environmental factors which may favour, challenge, or destroy the possibilities of reproduction. This four-fold system applies, of course, to man as to other animals, but Waddington proposed that it might provide a theoretical model, or at least a number of interesting suggestions, for the interpretation of the evolutionary processes apparent in human history. If one sees the creation of the mature organism from the fertilized egg as a continuous series of chemical accretions and processes going on under controls established by the 'information' stored in chromosomes, then, at this level of abstraction, the theoretical system devised by biologists to account for evolutionary change might conceivably apply to the changes occurring in the more complex, but essentially similar, passage of information from generation to generation of men by a multiplicity of extra-genetic channels.

For example, the genetic make-up of a population tends to resist disturbances which might change it by natural selection; after such a disturbance is withdrawn, the frequencies of genes in the gene pool return towards their previous values. "Something near to this biological genetic homoeostasis in its strict sense . . . are the somewhat nebulous, but often easily recognizable, qualities which are often spoken of as national characteristics, such as Jewishness, or Indianness". Another specific analogy is suggested by the process of introgressive hybridization in plants, which results from the persistence or loss of whole chromosomes. When this happens, a whole "chunk of genetic information", more or less randomly associated, is passed over. The agglomerations of cultural items passed between social groups sometimes appear to be fortuitously associated in a similar way, like trousers with Western technology.

Mr. Maynard Smith's commentary, and the subsequent discussion, fastened on the empirical character of genetic transmission and mutation on one hand, and human history on the other, and not on the conceptual utility of Prof. Waddington's models. Prof. Waddington's picture of an epigenetic landscape formed into watersheds, gullies and valleys by developmental controls is presumably a crude heuristic representation of a very complex process about which, even yet, little is known; it is a way not so much of explaining facts as of keeping what is to be explained in mind. Seen in this light, there is probably something to be gained by a method-starved science like sociology from such broad sketches, taken not as a means of suggesting testable hypotheses but as illustrations of the conceptual strategy employed in a related, and more sophisticated, discipline. Mr. Maynard Smith, however, chose to attack this—and by implication, any other—attempt to work from biological to historical explanation. The material differences he cited are not in dispute: the sub-human evolutionary system works with little or no transference of characteristics acquired metagenetically, whereas there is continuous alteration of social institutions and culture by the interaction of individuals with each other, with their social inheritance, and with their physical environment.

In fact many, if not most, of the sociological analogies quoted in Waddington's paper are very dubious parallels to the genetic and epigenetic models brought into play. The resilience and durability of Jewishness can scarcely be equated with lack of adaptability; this is a familiar sociological instance of cultural adaptation to manifest or latent subordination, along with the well-defined characteristic speech and manners of Negroes in the southern States of the United States: and the association of trousers with steam-engines and trading posts is only non-functional in a very restricted technological sense.

Maynard Smith took the view that the Marxist interpretation was the best attempt so far made at a usable theory of history, its weakness lying not in any fundamental error in Marx's own approach but rather in the failure of his followers to treat his ideas critically or to modify them in the light of advances in other fields. He did not think that one could usefully start from evolutionary theory and then attempt to find historical analogies for the various entities and items involved. Prof. Waddington, he said, had failed to point to any process in history comparable to natural selection, the most important single concept in the theory of evolution.

I have little doubt that a quick glance through the record of patented inventions, or the history of revolutionary epochs in England, France and Russia, even a reading of "Doctor Zhivago", would reveal plenty of instances of natural selection at work in the field of technological or political innovation. The crux of the difficulty lies, as Dr. J. Bronowski hinted at the end, in our present incapacity to isolate a single 'billiard-ball' entity from which to build explanations of variation in human society, as biologists have done with the gene—the unitary member of a pool of available characteristics constantly replenished by mutation and reduced by natural selection.

For Bronowski, this represented a failure by sociologists to respond to the challenge of Darwin's work. It was a double challenge, and a double failure. The first was the implicit question in his work of how variation occurred, a question which the later science of genetics was developed in order to answer. The second was the introduction of the notion of chance into rational explanation. This had, he claimed, proved a necessary foundation for the future not only of biology but also of physics.

In reality, chance has figured very largely in the historian's rendering of his subject. It accounts partly for the outlawing of pattern, interpretation, and theory by historians, and becomes explicit, though disguised, in the remark of H. A. L. Fisher's, quoted with such approval by K. R. Popper: "Men . . . have discerned in history a plot, a rhythm, a predetermined pattern . . . I can see only one emergency following upon another . . . only one great fact with respect to which, since it is unique, there can be no generalisations". But historians have used chance as a flag of surrender rather than as a weapon, and students of society have been content to name tendencies rather than establish laws. Prof. Morris Ginsberg's paper, "Social Evolution", was itself an admirable demonstration of the classic procedures of sociologists, and of the very different manner in which they have developed the concept of evolution and met the questions it poses. It discussed at some length attempts by nineteenth-century and later social scientists to develop evolutionary interpretations of the course of development of language and technology, and less successfully, of religion and law. He then presented his own view of social evolution as a process of development through higher levels of organized complexity of rational ideas, this process being effected by the human capacity for the intercommunication of ideas and skills.

Prof. Lancelot Hogben, by contrast, made his contribution on "Darwinism and Human Society in Retrospect" an exercise in the interpretative view of history he has made his own—which one would like to call philotechnic commensalism: the fortuitous concurrence and subsequent interaction of circumstances, generating complex causal processes which determine the direction and the variations in the rate of cultural development in different sections of the human species. The technological backwardness of the African is thus related to the susceptibility of horses to trypanosomiasis, which "has condemned Africans south of the tropic of Cancer to be their own beasts of burden in territories where malaria, yellow fever, hook-worm infection, schistosomiasis and many other diseases only lately recognized by medical science exact a heavy toll from the vitality of the people". Furthermore, "every change of the human environment through human interference signalizes a new accretion of transmissible experience and a new potential of further change. Because of this, human society is a unique ecological system". Thus, Darwin's work fits logically into its historical position when seen in the context of the stage reached by technological developments available in England by the mid-nineteenth century; the most significant circumstances being the greater facilities for sea travel offered by steam power, which "both greatly enlarged opportunities for a global survey of living beings and forced the problems of geographical distribution on the attention of naturalists", the accumulation of evidence for evolutionary succession provided by the work of survey and excavation undertaken during the railway-building period, and the major improvements in the microscope. The formulation and reception of Darwin's contribution to evolutionary theory similarly falls into place among the controversies over the criteria which should determine admission to the universities, the Civil Service, commissioned rank in the army and other controllerships, the debate over free competition as a principle of economic welfare and a social ethic, and the re-sharpening of the Abolitionist conflict in the years before the outbreak of the American Civil War.

In turn, the grand theological debates of the next forty years appear now to be locked firmly within their ideological setting; and the fruitless search for a complete genealogy of organic creation, Hogben also suggested, is visible now as the inescapable fate of a biology unprovided with the means of distinguishing adequately between hereditary transmission and genetic variation.

While Hogben's and Waddington's contributions inevitably dominated the conference, as latter-day reflexions by Darwin's scientific successors on the possibilities and limitations of a biological view of human society, other topics bulked larger than this short notice can easily show. Prof. Basil Willey's introductory account of the descent of Darwin's own theories from previous writings, although stretching back to Empedocles, was subject to a good deal of emendation in later discussions; his restriction of the effect of his work to the theological debate was deplored, and his view of Darwin's ultimate religious position as "helping to restore buoyancy to religion by forcing it to abandon some of its more untenable defences" was rejected by both *rapporteurs*. His paper also, however, bore on Darwin's introduction of the notion of chance into the rational interpretation of universal destiny, ideas far more disruptive than Newtonian mechanics, which had made the retention of the notion of design and of Designer plausible.

Mr. S. A. Barnett, in the last session, returned to the attack on Prof. Waddington's side with a range of suggestions from the study of the behaviour of bees, rats, birds and fish which might throw some light on behaviour in infancy, on motivation or emotion, and on the nature of language and human communication in general. Mr. Tom Burns, in the final paper, regarded these suggestions as limited to a very small field of human conduct, which characteristically selected courses of action from the wide range of possibilities available as normative guides to members of any society.

At the close of this conference, Dr. Bronowski remarked that no title could have lent itself better to so diverse an array of papers on such different subjects. Survivors of conferences on cybernetics may dispute this, but a conference which began with observations on the "history of man's endless probings into the mystery of existence; his thoughts about the nature of reality, about the administration of the universe . . ." and ended with a muted discussion on chance as the mechanism of irreversibility, and thus as the instrument of the universal order apprehended by man, has some claim to catholicity. It was also, far more frequently than one expects any conference to be, absorbingly interesting and seminal.

The conference papers will be published in book form.

TOM BURNS

OBITUARIES

Dr. L. J. Spencer, C.B.E., F.R.S.

LEONARD JAMES SPENCER, who died on April 14 at the advanced age of eighty-eight, was fourth in a line of distinguished keepers of minerals in the British Museum. His predecessors were Story-Maskelyne, appointed the first keeper of the department a century ago, Sir Lazarus Fletcher and G. T. Prior. All three were Fellows of the Royal Society, to which Spencer also was elected in 1925. He was made C.B.E. in 1934, he was given the Murchison Medal of the Geological Society in 1937, and the Roebling Medal of the Mineralogical Society of America in 1941. He was an honorary member of the Mineralogical Societies of Germany and of America, a senior Fellow of the Geological Society of London, and was president of the Mineralogical Society during 1936–39, and its foreign secretary from 1949 until his death.

Spencer was born at Worcester on July 7, 1870, the eldest son of James Spencer, for many years headmaster of the Day School Department of Bradford Technical College. According to a note in a local paper on the occasion of his appointment to the British Museum, he was "nurtured on examinations" and "when he had just completed his seventh year he turned his serious attention to geology . . .". From Bradford he went with a Royal Exhibition to the Royal College of Science for Ireland, taking a first in chemistry. Thence with a scholarship he went to Sidney Sussex College, Cambridge. He won the Harkness Scholarship in 1893 and successfully competed for a vacancy in the Department of Mineralogy in the British Museum (Natural History) in the same year. He then went for six months to Munich to study under Paul Groth, using his Harkness Scholarship money for the purpose, and returning to take up his appointment at the Museum on January 1, 1894. He married in 1899 Edith Mary, daughter of Islip J. Close, of Mortimer, Berkshire, and leaves a son and two daughters.

Spencer's main achievement in the Department of Mineralogy, apart from his scientific research work, was the establishment of the system of registration, labelling and card-cataloguing the mineral collection. After Prior became keeper in 1909, Spencer did a great part of the registration himself, and one result of his work and of his careful training of those who followed him is that the National Collection of Minerals is now probably the best documented and indexed in the world.

In addition to all his meticulous work on the collection, Spencer's output of original papers was considerable. His publications number well over a hundred and range over a wide field of descriptive mineralogy. He published two books, on minerals and on precious stones, and he translated from the German two large quartos on the same subjects. He took up the study of meteorites after Prior's retirement in 1927 and contributed many papers on this subject to the *Mineralogical Magazine*.

The discovery of the meteorite craters at Henbury in Australia and Philby's discovery immediately afterwards of the crater at 'Wabar' with its slag-like masses of silica-glass black with included millions of tiny spheres of nickel-iron gave great impetus to Spencer's work in this field and led him also to take up the problem of the origin of tektites. He strongly advocated the theory that tektites are the product of the impact of great meteorites on the Earth's surface, a theory that still finds many supporters but remains unproved. It was his interest in these problems that led him at the age of sixty-four to accompany an expedition into the heart of the Libyan Desert to investigate on the spot the masses of yellow silica-glass discovered in 1932 by P. A. Clayton. He hoped to find a meteorite crater there, but returned with the problem of the origin of the glass still a mystery. Spencer retained a very active interest in meteorites right to the end of his life, and his very last publication on meteorites was a communication in *Nature* of March 8, 1958.

Spencer's work at the British Museum would have filled the working life of some men, but he seemed always to be doing the work of three. In 1901 he took over the editorship of the *Mineralogical Magazine* from Miers, and he continued to edit it until the end of 1955. Previous to 1901 he had catalogued mineralogical papers for the Royal Society Catalogue for 1883–1900, and he continued this for the International Catalogue of Scientific Literature for 1901–14. In 1920 the Mineralogical Society commenced publication of *Mineralogical Abstracts*, and Spencer edited it and prepared more than half the abstracts himself. When he retired he had edited twelve volumes covering thirty-six years. A dinner in his honour was given him by his friends in November 1950 on the completion of his fifty years as editor of the magazine, and he lived to see *Mineralogical Abstracts* appear in a new format as a joint British–American publication aiming at a still wider international coverage of the science.

W. Campbell Smith

Dr. Eric Berkeley Higgins

Dr. Eric Berkeley Higgins, who died suddenly on April 8 at the age of seventy-three, was an inventor of the classical industrialist type, which pioneered industrialism, and is still not quite extinct. He had the peculiar flair for chemical development which seems to combine art and science. After early success with Dr. Ormandy, he invented the use of nickel formate in the hydrogenation of oils, and found his capitalist in Hamburg, where he was busy getting the process started when the First World War broke out.

Higgins was arrested in November 1914, and became one of a large number of Englishmen collected, under very unpleasant conditions, from all over Germany. These finally arrived in the Ruhleben racing stables at Spandau, where most of them stayed for the duration of the War, under the supervision of neutral diplomats. The American ambassador soon condemned one barrack (twenty-four horse boxes with hayloft above) as unfit for human habitation, so this was handed over to the already very active representatives of the arts and sciences among the prisoners. The scientists included established research men in physics, chemistry and biology, one of whom eventually became a Nobel prizeman. Soon a laboratory for teaching and research in all these branches came into existence, and Higgins was one of its most active spirits. He had arrived at the camp with two young men just gazetted out of Woolwich, with a sound mathematical training but no science. Higgins made them both change to science as a career, and one of them received his knighthood for it.

The power which Higgins had to enthuse gifted youth, and gain their warm personal regard, played no small part in his subsequent success, which culminated in Catomance, Ltd., which he worked up from small beginnings on his inventions in waterproofing and mothproofing materials. When he showed the latter some years ago at a chemical exhibition in London, he directed attention to it by providing a few live moth grubs engaged in chewing wool, with a microphone and loudspeaker which made them audible to visitors. This naturally appealed to the B.B.C. reporter touring the exhibition, and all the world heard the nasty little fellows munching.

Higgins had a mind the energy of which seemed entirely undiminished by several spells of ill-health. He would be at it hammer and tongs, first at Liverpool making soap, then at Brentford on water-softening compounds and naphthol *AS* dyes, then at Welwyn Garden City on the intensive development work which brought prosperity. He enjoyed to the end the affection of the men and women who formed the firm which he created, and all his life-long friends.

H. Stafford Hatfield
